HAM RADIO FUN SECTION

On the cover: Winning entries from *73's* "QSL of the Month" contest, June 1996 through January 1997. Winners for each month have received a free one-year subscription or extension.

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateur Radio Today*, 70 N202, Peterborough NH 03458-1107. 73 Amateur Radio Today is owned by Shabromat Way Ltd. of Hancock NH.

Contract: Have you tried microwaves? How about amateur television? When's the last time you home-brewed a piece of equipment? Reading this contract commits you to trying something new or long-neglected. The *73* advertisers can supply you with whatever you need ... just don't forget to tell 'em *73* sent you.

Number 1 on your Feedback card

NEVER SAY DIE

Wayne Green W2NSD/1

Resolutions

The beginning of the new year is a good time to make changes. The Christmas holidays wind up the old year, giving us a chance to make a fresh start with the new one. What changes are you going to make?

Yes, of course I have some recommendations. Hey, if you give me an inch, I'll try to revamp your whole life for you. For the better. Are you game to try some changes that will (a) Make you much healthier? (b) Happier? (c) Wealthier? (d) Do a better job with your kids? (e) Bring adventure into your life? (f) Accomplish something you'll be proud to be remembered for?

That's a tall order, but doable, unless your (bad) habit patterns are so thoroughly ingrained that you are no longer even capable of change.

Let's start with adventure, since that's closest to home, hamwise. Pick something you haven't done yet, but which sounds like fun, and get cracking. It could be slow-scan, RTTY, packet, 6m, 10 GHz, the ham satellites, or even 160m. Read, ask questions, start setting up the gear, and learn. I hope you'll keep careful notes so you can help others avoid the pitfalls and blind alleys. Maybe I can even get you to do some articles for *73*? If I can just get you started, I guarantee you'll be in for adventure.

Take 6 meters for instance. When the band was opened after WWII, I didn't think much about it. I was busy having fun up on 10m and 2m. Then one day I turned on my old pre-war Meissner FM tuner. The FM broadcast band, as I recall, used to be at 50-56 MHz, with the 5m ham band from 56-60 MHz. Suddenly I was hearing a whole bunch of S-9 W6s and W7s pouring through. Well, it didn't take long for me to convert an SCR-522 transmitter to 6m and build a converter for my SX-28. As far as I know, I was the first station on 6m in New York City and I had a ball.

In those days everyone was crystal-controlled, so with my surplus frequency meter I could tell who was who locally just by checking the frequency. There was a scattering of hams around Northern New Jersey, Long Island, upstate New York, and Connecticut.

To help other hams find out when the band was open I set my rig up on 50.1 MHz with a code wheel keying it as a beacon. That attracted Perry Ferrell, who had a contract with the Air Force to investigate the propagation characteristics of the band. I got a nice Radio Amateur Scientific Observations (RASO) certificate from the Air Force for my participation.

Later, when Perry became the editor of *CQ*, this helped me get him interested in my RTTY work. And that led to my doing a RTTY column in *CQ*, which led to my getting Perry the job as editor of *Popular Electronics*. And that led to my becoming the editor of *CQ*. And *that* led to my starting *73*.

But then, every new thing I've done in amateur radio has led to some sort of adventure for me, so I hope you won't get fed up with me prodding you to try new modes and bands. I get so discouraged when I listen to 75m nets and 20m round tables, where it is obvious that everyone is just marking time with their lives until the Silent Key guy comes calling. How is that better than watching ball games or sitting in bars? It's like going to a gourmet feast and eating a hamburger.

I've written about health, wealth, and happiness before. Should I keep repeating myself? A good part of happiness is in your family. So how much attention are you paying to romance? While a new rig may really get *your* juices going, your wife will be far more responsive to romance. And don't you forget it.

One of the easiest ways to rekindle romance is with dancing. Yes, I know, you're a klutz and would rather turn off your linear and run barefoot than go dancing. So get one of Sherry's how-to-dance videos and see what happens. You could use the romance and Sherry can use the extra business. Call 800-43-DANCE for a catalog.

What will it take to get you to make the big health change for '97? With daily exercise, a healthy diet, stopping poisoning your body, drinking enough water, and stuff like that? No chance, eh? Well, 1997 is going to be whatever you make it, and the new year is a fine time to make the big changes in your life that will see you living healthier, happier, and wealthier. Or not. You can make my year for me by letting me know that I've helped you decide to make changes. Will I be getting a note from you, or perhaps a handshake and some encouragement at a hamfest?

I haven't been invited to the '97 HamVention yet, but perhaps I'll see you there in '98? A new, trim, slim, grinning you?

I got a letter recently from a reader who thanked me for pushing him many years ago to start his own electronics-oriented business. His company is now one of the top in the field and he's having the time of his life.

The Camel's Nose

As if we don't have enough trouble with the FCC slicing off chunks of our unused ham bands, now Congress is forcing the FCC to hack away at us. Yes, of course our ARRL ham lobby in Washington should have prevented this. But I'm not sure we have even a vestibule there, much less a lobby.

Congress, a collection of politicians (mostly lawyers) you keep re-electing, can smell money through 10 feet of lead. And their main purpose in getting elected seems to be to spend as much of your money as they can, including borrowing as much as possible from the future. So the aroma from the recent FCC spectrum auction made Congress impatient with the FCC's slowness in generating more money for their pork futures.

Just before going home for the holidays, Congress whipped through Public Law 104-208, and it was signed by Clinton Oct. 4th. This little baby slices off two 5 MHz chunks of our 13 cm band to be put up for auction. Slice and dice.

I know you won't forgive me for going back in time 30 years. That's when the ARRL stopped our ham growth dead and almost totally destroyed our American ham industry, wiping out about 90% of our ham dealers as well. But if this catastrophe had not happened—if amateur radio had been permitted to continue growing as it had steadily in the previous 17 years—today we'd have over 5 million hams, and our country would have over 4 million more technicians, engineers and scientists than it does now. And I don't think we'd have either unused microwave ham bands or any problem with Congress and the FCC slowly putting what's left of us out of our miseries.

I don't think we would have lost all of our consumer electronics industries to Japan either.

Where have the kids all gone? They're rushing to the Internet, where you'll find endless teenagers having a ball with chat rooms instead of chasing DX or gabbing on 75m. Or getting on our ham satellites with packet.

If an ARRL director were to come to you, wringing his hands, asking what, oh what, can be done about this, what would you say?

I'll give you a hint. There are two things I can think of that the League could do to start turning this situation around. No,

LETTERS

From the Ham Shack

Neil V. Friend W2AMY. Thank you for printing WA8YKN's article on "free energy" devices which appeared in the September issue. Having read several articles on "zero-point" energy without the term being defined, I found his explanation enlightening.

Concerning the discussion of the "N" machine, however, I submit that the machine follows known laws of electrical power generation by mechanical-magnetic means and draws no power from "N space" or other sources. Any voltage or current generated is strictly the result of relative motion between a conductor and a magnetic field as occurs in any generator or alternator (read your *ARRL Handbook*). I also submit that the magnetic field does rotate as one with the magnetic cylinder, in spite of Tesla's reported conclusion that it remains stationary (a point discussed later).

Anyone determined to construct a copy of DePalma's machine would be well advised to first build an inexpensive small-scale version, as I did, for testing after considering the following discussion.

In this discussion, it is assumed that the copper disc, shaft and magnets shown in **Fig. 3** of WA8YKN's article all rotate as a single unit and the disc is electrically connected to the shaft. Observe that in **Fig. 3** of the article the magnet flux (not shown) surrounds the entire cylinder, while becoming weaker with distance from the cylinder. This is basic magnetic theory.

Again referring to **Fig. 3**, note that the brush (and part of its lead closest to the brush) in contact with the copper disc is bathed in the outer magnetic flux from the cylinder. The brush and its lead are stationary while the magnetic field rotates so that there is relative motion between them, which induces a voltage in the brush and that part of its lead within the field. The induced voltage will depend on the speed of rotation and flux density but, due to the limited exposure to the field, the voltage will be low. *This is the sole source of any power generated by this machine* as evidenced by the observations. If the copper disc is replaced by one of significantly greater diameter, the brush and lead will be isolated from the rotating magnetic field with a consequent reduction or elimination of generated power.

Going back to the smaller copper disc, we can relocate the brush to a slip ring mounted on and insulated from the shaft and well out of the magnetic field. Restore the circuit by soldering a jumper wire between the outer edge of the copper disc and the slip ring. Once again, with this brush and its lead now isolated from the rotating magnetic field, the power generated will be zero.

I have verified the above with the help of a fractional horsepower DC motor, four 1.12" diameter ring magnets and some lathe work. Measured output at 2,300 rpm while using a 1.2" diameter brass disc was 2.75 mV open circuit and 1.6 mA short-circuit current. With a 1.5" diameter brass disc or the slip ring version there was no detectable output.

WA8YKN also notes that rotating the magnet alone produced no voltage in a stationary disc and caused Tesla to conclude that the field did not rotate with the magnet. This conclusion is unreasonable if one considers a cylindrical magnet that has a non-uniform field. It appears to absurd to imagine that the non-uniform field would remain non-uniform and stationary while the source of this field rotated.

WA8YKN cites a DePalma test which produced 1.05 volts at 7,200 amps, but it is not stated whether this was an open circuit voltage and short-circuit (no load resistor) current. Such a high current would be expected in a short circuit fed by the interaction with an intense magnetic field rotating at high rpm. Both current and voltage can be expected to drop dramatically if measured with a suitable load on the output.

I have a copy of a data sheet on another DePalma test which shows 1.872 volts and 3.492 amperes, which they multiplied together to get an output of 6.538 watts. From the data sheet it is obvious that these are open-circuit voltage and short-circuit current readings and the computed output is therefore meaningless (again, read your *ARRL Handbook*).

With this machine all may not be as it at first seems and your efforts may be better expended on some other device.

Spoilsport... Wayne.

Warren Rudolph W4OHM. Wayne, you wondered how many still have the October 1960 37¢ issue. I have every issue from #1 to now, all in binders. I was licensed W4OHM after WWII and have held the same call ever since. I am a chartered member of the Shenandoah Valley Amateur Radio Club and obtained my first class commercial license and radar endorsement. I've also written articles which have been published in several radio magazines. I went on the Winchester police force in 1942 as a dispatcher and retired as Chief of Police in 1980 with the rank of major. I am presently active on 10 and 2 meters and am an active member of the local radio club.

Don Walters WA8FCA. Re your August editorial and keeping our 144, 220, and 420 MHz bands: Perhaps we should pitch to the potential buyers that we need at least a couple of MHz for amateur radio because it provides a "hands-on" training ground for and a place where future technicians and engineers can develop an interest in communications and electronics, something they do not get in trade schools and colleges. And regarding the sale of the spectrum, I believe that it should be leased for a period of time with the lessee paying an initial fee which is the highest bid and then a yearly lease payment based on a percentage of what they paid initially for the term of the lease. This provides a continuing revenue stream to the government for a public resource being used for commercial and private gain. Why? Because the spectrum is a national resource that should be kept publicly held while generating an initial and a continuing revenue stream for the private use of this public resource. *(1)*

I have been a ham since 1962 and have learned much from it that has provided countless hours of fun and learning, as well as provided a training ground for learning some marketable job skills that have enabled me to always find a job. But just as mainframe computer programmers are dinosaurs, nearly having outlived their usefulness, could it be that amateur radio has also outlived its usefulness? I hope not. If not then we must redefine amateur radio and what benefit to our society/country it can/does provide and then let our society and country know!

Detroit radio station WJR is now airing Art Bell's show. It's a little too late at night for me to listen to it, but I might start taping it.

When is *73* going to get an E-mail address for letters and perhaps sending manuscripts for articles? *(2)*

Amateur radio/computer swap and shops do not advertise as much as they used to. I remember the local swap and shops always being crowded and people knowing about them substantially before their date. But not these days. There is just not the same level of advertisement and promotion that there used to be. *(3)*

I have a younger brother whose past lifestyle may now be causing him medical problems. He is not HIV positive, but appears to be sick too often with viral infections and the like. I am seriously thinking of building the Bioelectrifier circuit to see if it will help him. If I do build one I will let you know if the results are promising or not. *(4)*

Keep up the *great* work, rattle those chains, keep pushing us all to do something, keep the editorials interesting and mind expanding. Perhaps it might just get enough, or at least some, people moving!

Hmm. Don, on (1), for some leaping liberal reason you are expecting corporations to actually consider the future. It doesn't happen with people, corporations or politicians. Get real. (2) Now and then I look to see what has accumulated at Design73@AOL.com. (3) Ham radio, as well as our hamfests, has sunk below the public awareness horizon. When will clubs and hamfest organizers get live PR persons? I got a hamfest announcement for a Detroit October hamfest a week after my October 73 came. (4) The bio-e won't hurt and could work wonders for your errant brother. Lemeno... Wayne.

NEVER SAY DIE

Continued from page 4

they're not doing either one. Instead they're passing the hat, asking for more money.

But, let's see what you come up with. How's your creativity doing?

ARRL Worried

I've been getting form letters from the League confirming that they are, at long last, starting to worry about the potential loss of ham bands which I've been gloom-and-dooming about in my editorials for a couple of years or so. Naturally they've used this as an excuse to rattle their tin cup, begging for donations. Hey guys, you're a multi-million-dollar publishing enterprise. If you need more money for something, raise the subscription price for *QST*.

As far as donating money for the protection of our frequencies is concerned, it seems to me that I remember money being set aside for that before. $100,000 comes to mind. Of course, I'm getting old now and maybe my memory isn't as good as it used to be, but I seem to remember visiting the lavish League hotel suite in Geneva's most expensive hotel during an ITU conference, and the flying over of directors for parties, all at the members' expense. And hey, wasn't there something about a League president who vacationed away a big bunch of that frequency-saving money with a girlfriend in the Caribbean? Golly, what was his name? I forget if I ever wrote about that or not.

The League letters confirm that there really is a major problem—that our UHF ham bands in particular are in serious jeopardy. As I've been saying. But, you know, I didn't see anything in the letters about what the League would do to stop the incoming tide. The demand for more and more satellite and other UHF channels is going to continue to grow exponentially, and we have the League saying they need more money. To do what, guys? What are you going to do, send baskets of money to Washington to be doled out (no pun intended) to Congress? You can't possibly match the commercial lobby money, so what will you do if we send you a big check? Party some more?

Yes, I have some good ideas on what could be done to help stem our loss of satellite bands. But first I want to know if (a) a significant number of our active hams really give a damn; and (b) what the Tech/Novice hams (now over half of us) think. Do many of them really care? In other words, if the League actually came up with a workable plan, but needed the support of the membership, would they get it? However, as far as I can see, other than begging for money, they have no plan of action.

Why should a 75m op care one whit about what happens to our 3300 MHz band? Or even 1300 MHz, for that matter? I suppose that the 20m DXers, contesters, certificate hunters, rag-chewers, the CW-forever crew, and so on couldn't care less what happens to our unused (and presumably unneeded) bands.

Until nearly 1970 the top half of 2m was a virtual desert. Heck, when *CQ* magazine proposed taking it away and making a new CB out of it there was almost no fuss. Then along came repeaters. Now we're willing to fight to hold onto our precious repeater band. But hey, why bother about our 500 MHz-wide band up at 10 GHz? Or a couple of unused 5 MHz segments of the 2300 MHz band? People in general, and hams in particular, don't think much about the future. If they did they wouldn't smoke or be grossly fat. These are denials of the future consequences of our actions.

So, guys, if we send you money, what will you really do with it? Will it be like sending money to Washington? Will it just go in the pot and be that much more to spend on current enthusiasms?

The Michigan Miracle

Maybe you can remember not long ago when Michigan had one of the highest unemployment rates in the country. When the state was a national disaster, verging on bankruptcy. While I'm not a fan of all the Republican party planks, the

Continued on page 22

QRX . . .

FCC Stops Renewal Reminders

As of October 22, the FCC has ceased issuing Form 610R license expiration notices—reminders to hams that their tickets are going to expire within the next 90 days and that they must request renewal. The last notices sent by FCC covered into February 1997, although the specific date was not available. A Form 610R for renewal must be returned by mail only to the FCC.

The demise of the Form 610R means that hams—whose licenses are issued for 10-year periods—must take the initiative to remember the renewal date of their tickets and file a Form 610. AN FCC spokesman in Gettysburg says the Commission hopes to have a Form 610 available soon on the World Wide Web to permit on-line renewals.

From *The Repeater*, official newsletter of the Alamo Area Radio Organization, San Antonio TX.

Have You Applied for a Vanity Callsign?

The FCC will not start making any grants for first-day filers until all day-one applications have been entered into the FCC's computer. Then applications will be processed randomly from among those in the first-day pool.

The number of hams taking advantage of Gate 2 has been less than anticipated. As of September 25, 1996, the FCC had received 5,297 Gate 2 applications. First-day vanity filers totaled 4,527, a number that even surprised the FCC, which had been expecting a larger flood of Gate 2 filings. The FCC said 4,188 paper applications and 339 electronic applications were received the first day. Another 770 applications, mostly paper, had showed up by Wednesday, September 25. Slightly more than 7% of the applicants used the FCC's newly inaugurated electronic filing system.

Among the major headaches for the folks in Gettysburg are applications that contain illegible information. FCC personnel have been instructed to skip over requested callsigns they cannot decipher. Also, some electronic filers have been sending their payments to the wrong Post Office box in Pittsburgh and using the FCC Form 159 designed for use by those filing on paper. The FCC said that contrary to instructions on the electronic application form, electronic filers should not forward a copy of their license to the FCC by mail. FCC personnel have no way to match up licenses with applications, and they don't need the license copy to process the application.

The FCC said that some applicants apparently have had second thoughts about changing their callsigns and have contacted the FCC to pull their Gate 2 paperwork. The FCC says that cannot be done. Those issued a vanity callsign who decide they like their old callsign better will have to pay another $30 and reapply under Gate 1.

If the FCC is unable to grant any of your vanity callsign requests, your application will be dismissed, and the FCC will notify you to that effect. But the Commission will not return your $30 until you request a refund in writing.

Excerpted from *Harmonics*, October 1996, official newsletter of the South Jersey Radio Association.

Alaskan Hams Sizzle During Forest Fires

It's a sign of how times have changed that ham radio was not even considered as a communications link by Emergency Management, because of the wide use of cellular phones, during the recent disastrous forest fires in the Big Lake area of Alaska. The Amateur Radio Emergency Service Net wasn't part of the scenario. Hams were used for some of the communications during the Miller's Reach fire, but only after going to the Emergency Management people to make their availability known.

Communications ground to a halt when telephone lines and cellular phone frequencies were so overloaded they jammed. So many people were trying to get in touch with loved ones in fire-threatened Southcentral Alaska that the local cellular companies had radio stations begging people not to use their cellular phones; landlines were taking a minute or more just to come up with a dial tone.

Hams to the rescue! "My XYL, who is not a ham, and rarely pays attention to what I am listening to or doing on the radio, was totally impressed with the number of hams who suddenly came from nowhere to be just about everywhere," wrote Bob NL7QP, editor of *Mara News*. "We must continually make our communities aware of the importance of amateur radio during a disaster. We need to make better use of the bands we have, and encourage that use so we can retain those bands."

Condensed from an editorial in *Mara News*, the official newsletter of the Matanuska Amateur Radio Association, Wasilla, AK.

The Boy and the Frog

A boy was crossing a road one day when a frog called out to him, "Kiss me and I'll turn into a beautiful princess."

The boy picked up the frog and put it in his pocket.

The frog said, "If you kiss me, I'll turn into a beautiful princess, and I'll stay with you for a week."

The boy took out the frog, smiled at it, and returned it to the pocket.

The frog cried, "If you kiss me and turn me back into a princess, I'll stay with you forever, and do anything you want!"

Again, the boy took out the frog, smiled at it, and put it back. After a long pause, the frog asked, "What is it? Why won't you kiss me?"

The boy answered, "Look, I'm an amateur radio operator. I don't have time for girlfriends, but a talking frog—hey, that's cool!"

Learn More About QRP

Founded in January 1994, CQC brings amateurs interested in low power together, and endeavors to expand their interests and give them a forum in which to discuss problems and accomplishments. Besides its bimonthly meeting for local members, CQC publishes a bimonthly newsletter, *The Low Down. The Low Down* contains technical articles, product reviews, member news, upcoming activities, and an activities calendar. CQC membership is open to anyone interested in QRP.

In eastern Colorado try the Colorado QRP Club net every Monday evening at 8 PM on the 147.225 repeater in Golden, and on the 145.160 machine in Colorado Springs. They also use 146.445 simplex. On HF, call "CQ CQC" at 8 PM on 3710 kHz (the national 80 meter QRP frequency).

For an application form, send an SASE to Mark Meyer, 14153 West First Drive, Golden CO 80401. Membership dues are $10 a year, including a subscription to *The Low Down.*

The ScopeMixer

An adventure in ham radio systems integration.

Dave Evison N6GKC
153 Park Avenue
Palo Alto CA 94306

How would you like to adjust your antenna tuner while your rig is terminated in a dummy load? (Your final amplifier and fellow hams sure would!) Or how about monitoring your SSB signal and checking the peak envelope voltage for clipping and crossover distortion? (Wow, talk about good operating practice!) And wouldn't it be great to check the rise and decay time of your CW envelope and be able to *see* those chirps or clicks? Or how about being able to detect and measure harmonic radiation and other spurious products (just like the big guys)? Well, even if you're sitting on a very thin billfold, you can manage all of this—and more—with a ScopeMixer System. While it's primitive by commercial standards, it can provide you with a versatile measurement system at very low cost. The ScopeMixer will empower you (without spectrum analyzers and other professional laboratory instruments) to produce superior, well-tested designs.

The ScopeMixer System is an example of ham radio systems integration: a couple of simple circuits containing only one active component (a 10-cent transistor), an inexpensive 40-year-old kit oscilloscope ($15 at any ham flea market), a secondhand MFJ SWR Analyzer used as a local oscillator (about $40—but you may already have one of these handy little devices). Now that's real ham engineering!

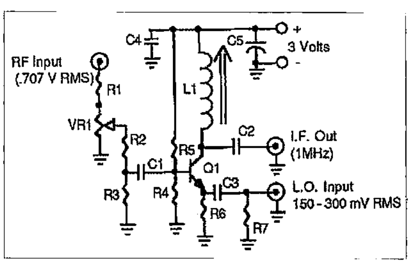

Fig. 1. ScopeMixer schematic.

The ScopeMixer is a good example of recycling older technology that is rarely used today: the wave analyzer. The wave analyzer has been supplanted by the spectrum analyzer in most commercial laboratories, but it's still simple, inexpensive, and provides an impressive measurement capability.

The design criteria for the ScopeMixer were to keep the cost and parts count low and use only readily available parts. The result is a straightforward bipolar mixer using a 2N2222A transistor (**Fig. 1**). The RF is applied to the base, the local oscillator to the emitter, and the IF taken from the collector—it really couldn't be simpler—and with 2N2222 transistors selling for less than 10 cents, it couldn't be much cheaper. There is no IF transformer. Instead, an old broadcast "ferrite loopstick" is used. The unit draws less than 10 mA and requires only a 3 volt supply (a couple of AA batteries in series).

How it works

The ScopeMixer is a simple application of a heterodyne mixer. It converts the RF input to a 1 MHz intermediate frequency, which is well within the bandpass of the ancient oscilloscopes. While any frequency between about 550 kHz and 1600 kHz can be used for the IF, 1 MHz simplifies setting the local oscillator when measuring harmonic and other spurious products.

The ScopeMixer was designed to use an MFJ (or Autek) SWR Analyzer as a local oscillator working either 1 MHz above or below the RF. Harmonics and other spurious emissions are measured by establishing an IF reference level at the carrier frequency, then tuning the local oscillator up or down from the carrier frequency and observing signals that develop an IF of 1 MHz. For example, if a reference carrier of 7 MHz having a second harmonic component is connected to the ScopeMixer, it will produce an IF of 1 MHz at 6 MHz and 8 MHz (reference frequency) and at 13 MHz and 15 MHz (the second harmonic). The amplitude of the harmonic responses when compared to the amplitude of the reference carrier will determine their relationship in decibels (dB).

To understand the input circuit refer to **Fig. 1**. The values of R1 through R4 were calculated to deliver 25 millivolts rms to the base of the 2N2222 when 707 millivolts (.707 volt) rms is applied at the RF input. While the 2N2222 in this configuration will work with levels significantly greater than 25 mV at its base, it becomes quite nonlinear. Maintaining 22

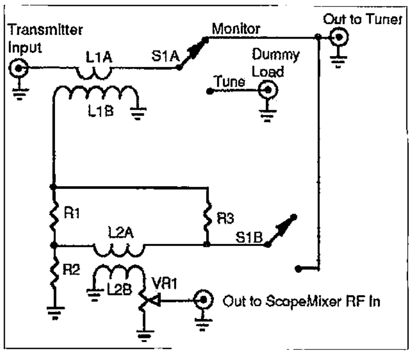

Fig. 2. ScopeMixer Range/SWR Unit.

to 28 mV at the base will enable the ScopeMixer to display levels as low as -30 dB (referenced to the input level).

The pot will allow fine-tuning to the desired 25 mV when levels slightly greater than 0.707 V rms are applied to the ScopeMixer RF Input. I recommend that the pot be kept full-on and that the input to the mixer be trimmed using the range control pot on the Range/SWR Unit.

The Range/SWR Unit samples the RF source to be monitored. It accommodates RF levels from 180 mW to over 100 W. It also includes an antenna bridge for performing "stealth" antenna tuner adjustments. In **Fig. 2,** you see that the RF signal to be monitored/measured is sampled inductively by L1A/L1B. With S1 in the tune position, the RF source is terminated in an external dummy load, and a small sample of the RF energy is used for antenna bridge excitation. R1, R2, R3, and the antenna system are configured as a simple antenna bridge—and the ScopeMixer is used as the detector. Using the oscilloscope readout of the ScopeMixer provides great sensitivity, smoothness and resolution. L2A/L2B transfer the signal developed by the unbalanced condition of the bridge to VR1 which provides level control to the ScopeMixer. VR1 functions as the RF range control. With S1 in the monitor position, the unbalanced bridge signal is fed to the ScopeMixer through L2A/B and VR1. This signal is used as both the calibration level for SWR measurements and reference level for attenuation measurements.

ScopeMixer construction

I'm a great fan of Wes Hayward and his Ugly Construction, and my ScopeMixer is an excellent candidate. If you're not familiar with ugly construction, check the *ARRL Handbook* (it's actually listed in the index of some issues under "Ugly"). The accompanying photo shows a prototype ScopeMixer mounted in a small metal box (note that ugly construction was retained).

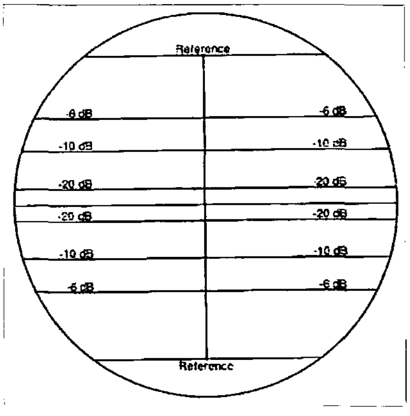

Fig. 3. Calibration overlay grid.

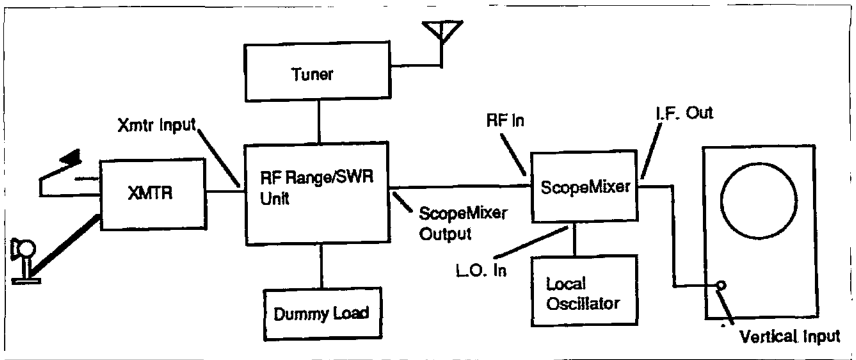

Fig. 4. ScopeMixer Range/SWR Unit system setup.

Range/SWR Unit construction

L1 and L2 are RF transformers made by winding secondaries over off-the-shelf Radio Shack™ 100 µH RF chokes (RS #273-102). Before winding the secondary onto L2 (30 turns #26 enameled), it's a good idea to put a layer of masking tape over the windings of the choke. The primary (L1A) is four turns of stranded, insulated wire (about #20).

The Range/SWR Unit should be enclosed in a suitable chassis box for both shielding and prevention of RF burns. Use a good quality wafer-type switch (do not use a toggle-type switch) and ensure the switch is a break-before-make type.

Making a calibration overlay grid

A pattern for a calibration overlay grid is shown in **Fig. 3.** Using this overlay grid will simplify measurements and increase accuracy.

Make an overlay from the magazine pattern by copying the image onto an overhead transparency sheet. Then cut the overlay out and place it on the face of the cathode ray tube. Align the center horizontal line of the overlay grid with the oscilloscope trace.

Measurements

The ScopeMixer will allow you to make attenuation measurements in decibels (dB). Since dB measurements are relative measurements (compared to an identified reference level) you will be able to rely upon the basic accuracy of the oscilloscope's vertical deflection linearity—which in the case of the older kit scopes works out to be about 5%. Overall accuracy is cumulative and factors such as local oscillator leveling, gain-bandwidth product of the 2N2222, noise, etc., all contribute. But, after all, the ScopeMixer is for ham applications, not rocket science.

To minimize identified noise and gain problems, measurements should be performed on the X1 range and utilize the large CRT deflection (4 to 5 inches). In this manner, deflection accuracy will be limited to the vertical deflection linearity and the gain control will be closer to halfway on.

Using the scope attenuator to provide 20 dB gain (for example, establishing a reference level on X10, then setting the scope to X1 for measuring attenuation—equivalent to 20 dB gain) is not recommended because noise components increase dramatically as the variable gain control is set at or near maximum. A second reason for not using the scope attenuator in the measurement scheme is that above 1 MHz the scope's internal attenuator compensation adjustments greatly influence the actual gain/attenuation between steps, and among the three kit scopes used for this project, all three had severely maladjusted attenuator compensation.

Oscilloscopes with wider bandpass characteristics *do not* work well with the ScopeMixer system as they are sensitive to unwanted signals appearing in the IF output (local oscillator, RF fundamental, etc.). If a wideband scope is used, an IF transformer with a tuned primary and secondary will be required. The low cost of the older oscilloscopes, and their performance

in this application, justify their dedication to the system.

For amateur applications, measurements are generally made while performing adjustments for peaking or nulling. For example, you've just finished a QRP rig and you want to check for, and if necessary attenuate, harmonics and other spurious products. In this case your concern is not the accuracy of the harmonic level, but rather to be able to detect it and reduce it as much as possible. In this case the ScopeMixer will be able to display the spurious signal. You peak the display using the local oscillator, and then make adjustments to the rig, or substitute new components in the circuit, to reduce the level of the spurious signal.

There is nothing particularly critical about setting up the system. Use high quality RG 58U coax cable and BNC connectors, and ensure that excessive RF is not applied to the Range/SWR Unit. The power level should not exceed 100 watts. Interconnect the equip ment as shown in **Fig. 4**, and set the equipment as specified under "Equipment Setup."

In adjusting the loopstick, start with the slug in about halfway. Apply the local oscillator frequency (approximately 1 MHz above or below the RF input signal); set the pot on the ScopeMixer fully clockwise and adjust the Range/SWR Unit pot to the level of RF to be applied.

Key the transmitter and apply a CW signal to the system. Fine-tune the local oscillator to produce maximum vertical deflection and stabilize the display. Adjust the focus control for best trace. Then adjust the variable gain and vertical position controls to set the waveform peaks to the reference levels **(Fig. 6)**.

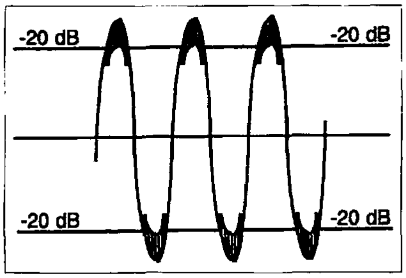

Fig. 5. Although the peak-to-peak amplitude of this waveform measures greater than -20 dB, "subtracting the fuzz" results in a more accurate measurement of -20 dB.

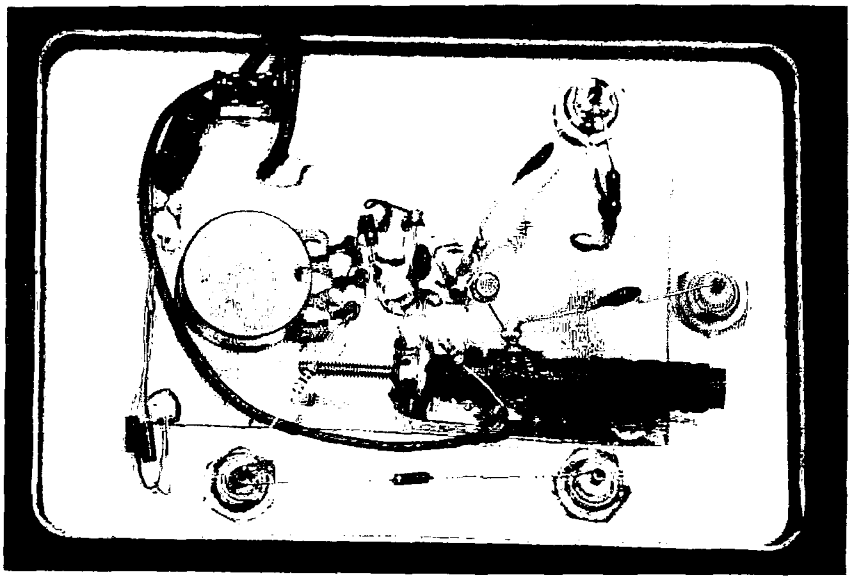

Photo A. *A peek inside the ScopeMixer.*

Note the frequency of the local oscillator and compare it to the frequency of the applied RF. If the frequencies are separated by more than 1 MHz, adjust the slug further into the coil: if separated by less than 1 MHz, adjust the slug out of the coil. Repeat this process until a 1 MHz ±10% IF is achieved.

To check the SWR function of the Range Unit and adjust the tuner for minimum SWR, interconnect the equipment as shown in **Fig. 4**. Set the Range/SWR Unit to the tune position, then remove the antenna tuner from the Range/SWR Unit. Key the transmitter and apply a CW signal. Fine-tune the local oscillator, and peak and synchronize the IF display. Set the waveform peaks at the reference levels (**Fig. 6**). Remove RF power.

Connect a 50Ω non-inductive resistor to the tuner port, then key the transmitter. The peak-to-peak display should be approximately 1/4 inch or less (**Fig. 8**).

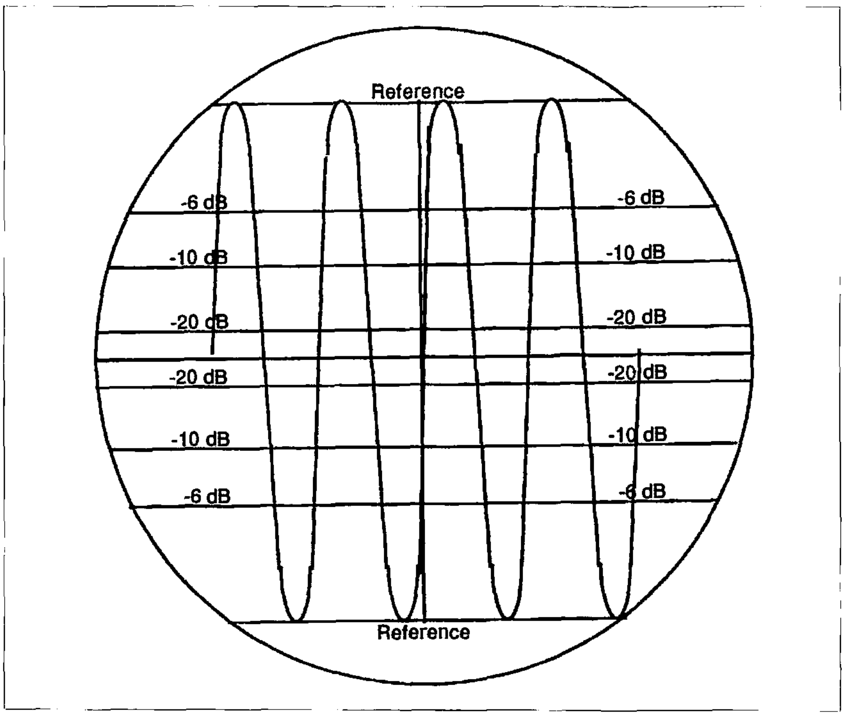

Fig. 6. *Reference level.*

Remember to subtract the fuzz. Remove RF power from the system. Remove the 50Ω resistor and reconnect the tuner and antenna system. Key the transmitter and adjust the tuner for minimum deflection.

Equipment setup

Oscilloscope front panel control settings:
- Vertical attenuator: X1
- Variable gain: 40
- Horizontal sweep: 100 kHz
- Horizontal vernier: 80
- Horizontal gain: 20
- Sync selector: Int +
- Intensity and focus for best trace.

Local oscillator (LO) (MFJ or Autek SWR Analyzer) settings:
- Frequency: 1 MHz below the RF source to be measured.

ScopeMixer settings:
- RF input pot fully clockwise, power switch on.

RF range/SWR unit settings:
- Set tune-monitor switch to monitor
- Set range pot according to the amount of power to be sampled. If possible limit the RF level for initial settings from 5 to 10 watts.

Measuring harmonics and other spurious products

First, establish a reference level at the fundamental carrier frequency being measured. Once set, the vertical gain control should not be readjusted until all measurements have been made and noted. The local oscillator is then adjusted above and below the carrier while watching the scope for intermediate frequency responses. Harmonics, of course, will be multiples of the carrier frequency, but other spurious responses will not. Once a response is detected, peak the signal using the local oscillator, and read its amplitude (in dB) from the calibration grid. The frequency of the spurious signal is determined by adding or subtracting 1 MHz (depending upon whether the local oscillator is operating above or below the spurious response).

Note: Below -20 dB, noise and the width of the trace significantly limit accuracy. With experience, you can improve such measurements by "subtracting the fuzz" from the measurement (**Fig. 5**).

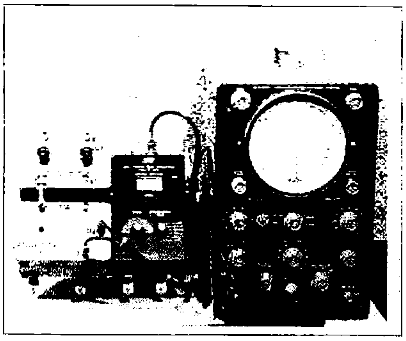

Photo B. ScopeMixer system with scope...

Monitoring modulation

Monitoring modulation is limited to observing the modulation envelope, but a great deal of information can be gathered in this manner—single sideband peak envelope voltage clipping and crossover distortion can be observed. Refer to the *ARRL Handbook* for more information on these parameters.

Examining keyed carrier waveforms

With the transmitter in the CW mode, key the transmitter by sending a series of evenly spaced dits and adjust the horizontal vernier to observe the keyed envelope.

Measuring SWR

Remove the antenna tuner from the Range/SWR Unit, then set the RF Range/SWR Unit to the tune position. With the transmitter in the CW mode, key the transmitter and fine-tune the local oscillator to peak the oscilloscope display. If the rig is SSB-only, set it to tune. Adjust the Range pot until the peak-to-peak signal is set to the reference levels on the calibration overlay grid. The oscilloscope vertical position control may

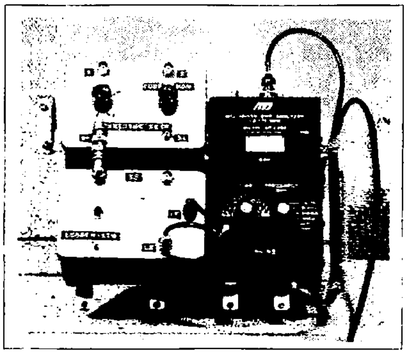

Photo C. ... and without the scope.

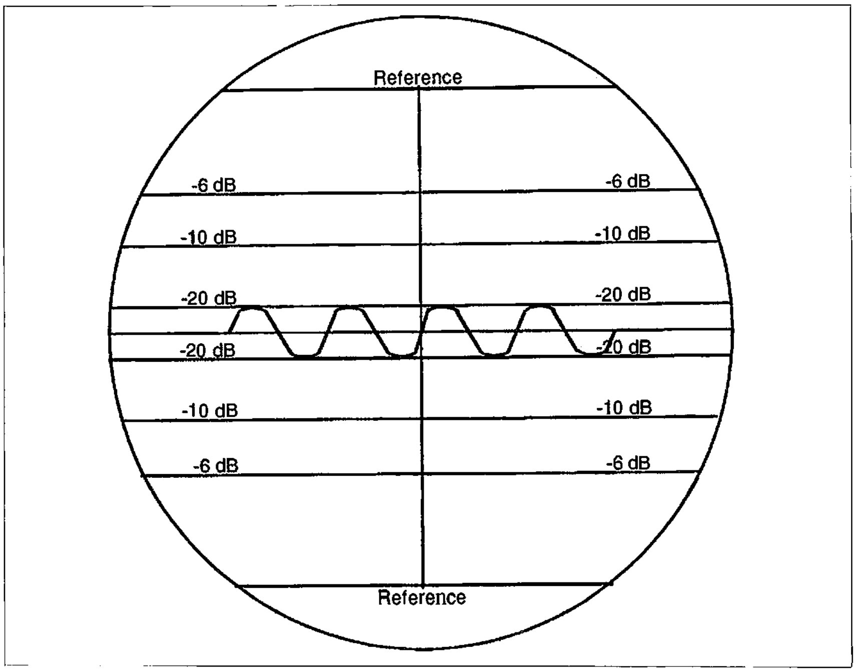

Fig. 7. -20 dB.

also require adjustment to position the waveform on the calibration grid (**Fig. 6**). Once set, remove RF power and connect a 50Ω non-inductive resistor to the tuner port. Key the transmitter. The peak-to-peak display should be approximately 1/4 inch or less (**Fig. 8**). Keep in mind that you need to subtract the fuzz (**Fig. 5**). Remove RF power from the system. Remove the 50Ω resistor and reconnect the tuner and antenna system. Key transmitter and adjust antenna tuner for minimum peak-to-peak display on the oscilloscope. A matched condition will result in a peak-to-peak display of approximately 1/4 inch (Fig. **8**). 73

Number 17 on your Feedback card

A Flexible Keyer

A weekend of investment; a lifetime of ease.

Parker R. Cope W2GOM/7
8040 E. Tranquil Blvd.
Prescott Valley AZ 86314

An inexpensive flexible keyer can be built with two 4000 series CMOS ICs to generate independently adjustable self-completing dots and dashes. The keyer can drive an inexpensive MOSFET cathode switch that will key anything from a solid-state QRP rig to a kilowatt tube final. The keyer includes an optional sidetone generator that can be used as a code practice oscillator while you learn to use the keyer.

The keyer described generates a keying waveform whose weight can be adjusted to suit your preference. This weekend project uses no critical parts or unique ICs, so, depending on the state of your junk box, construction costs can be low. Equations are given to allow modification of the design to fit the parts you have.

The keyer generates a keying waveform that drives a MOSFET transistor to cathode-key a tube type transmitter or switch a positive voltage to ground to key a solid-state exciter. Some solid-state transmitters switch a positive voltage in the exciter to ground for keying and refer to it as "cathode keying." That is likely a misnomer because the only cathodes are probably cathodes of semiconductor diodes. Just so we can all sing from the same hymnal, I will refer to switching a positive voltage to ground as "cathode keying."

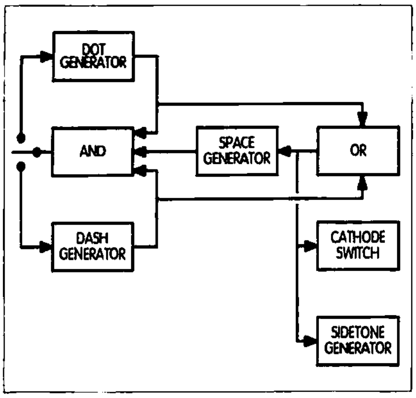

Fig. 1. The keyer is built around monostable multivibrators and combinatorial logic.

The keying speed is variable from less than five to about 30 words per minute with a single front panel control. Equations are given for selecting parts to allow higher keying speeds. The weight is adjusted internally and is maintained for all speeds. A front panel toggle switch is provided to produce continuous "key-down" for transmitter tuning. The optional sidetone generator can provide about 100 mW of audio to drive low impedance phones or a speaker. This power is adequate for most situations.

The functional block diagram in **Fig. 1** shows how three monostable multivi-brator pulse generators and logic elements can be used to produce the keying waveforms. One multivibrator generates the dash period, the second generates the space period, and the third generates the dot period. The space-to-dash ratio and dot-to-dash ratio of the keyer are adjusted independently. The selected ratio of dot/dash/space is maintained for keying speeds from 5 WPM to 30 WPM. The monostable

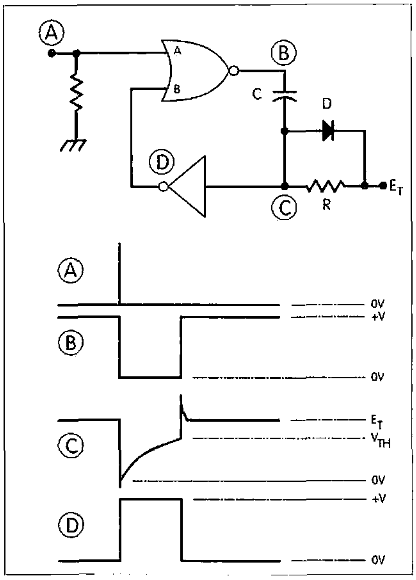

Fig. 2. A monostable multivibrator built with CMOS has these critical waveforms.

multivibrators used are non-retriggerable. Once a pulse is initiated, subsequent triggers during the period of the pulse have no effect on the pulse duration.

A typical monostable multivibrator is shown in **Fig. 2**. The timed period is determined by R x C, V_{TH} (a characteristic of the IC), and E_T, the timing voltage controlled by the "Speed Control." The threshold, V_{TH}, of 4000 series CMOS is between $0.45V_{DD}$ and $0.55V_{DD}$. V_{DD} is the supply voltage +V. While the match of thresholds from one chip to another may vary 20%, the match of units within an IC is very close. Therefore, the inverters are all within one IC to ensure tracking of the periods as E_T is varied. Each of the multivibrators uses one section of the CD4009 hex inverter. The ICs can be either AE or BE versions; use whatever is available.

In a NOR gate, the output is "low" (zero volts) when either input "A" or "B" is more positive than V_{TH}, and is "high" (+V) when both inputs are more negative than V_{TH}. In **Fig. 2**, the resistor at the "A" input of the NOR gate holds that input "low" until a positive trigger drives it above V_{TH}. The "B" input which is connected to the output of the inverter is "low" because the positive voltage, E_T, at the inverter's input is above V_{TH}. When a positive pulse is applied to the "A" input of the NOR, the output goes "low." This negative transition is coupled through C to the input of the inverter and drives the inverter's input below V_{TH}. The inverter's output goes "high" and holds the "B" input of the NOR gate high until C, charging through R toward E_T, reaches V_{TH}. While the inverter's output is "high," the "B" input to the NOR gate holds the output low and triggers to the "A" input have no effect. The stable state of the multivibrator is both inputs of the NOR gate "low" and the input of the inverter held "high." The unstable state, or timing state, has the output of the NOR gate low, C charging toward E_T, and the inverter output high.

The transition of the NOR's output from +V to zero will try to drive the input of the inverter negative (below ground) when E_T is less than +V. The IC's input protection circuit limits the negative voltage to one diode drop below ground. On the positive transition of the NOR's output, the positive swing on the inverter's input is clamped to E_T by the diode across R.

The voltage on the input of the inverter rises toward E_T at a rate controlled by R and C. The instantaneous voltage on the gate is:

$$V_c = E_T \times (1 - e^{-t/RC})$$

This can be rewritten in terms of t and RC:

$$-t/RC = Ln(1-V_c/E_T)$$
$$t = -RC \times Ln(1-V_c/E_T)$$

where t = time in seconds
R = ohms
C = farads
Ln = the natural logarithm
V_c = the instantaneous voltage across the capacitor
E_T = the speed control voltage

When the gate voltage V_c reaches V_{TH}, the output of the inverter switches. Since each pulse generator's period ends when $V_c = V_{TH} = 0.5V_{DD}$, the time of the pulse can be written as:

$$t = -RC \times Ln(1-V_{TH}/E_E T) = -RC \times Ln(1-0.5V_{DD}/E_T)$$
$$t = RC \times 0.69 \text{ when } E_T \text{ equals } V_{DD}$$

When all three pulse generators have the same V_{TH} and E_T, the pulse generators maintain their ratios as E_T is varied. The minimum pulse period (highest keying speed) occurs when E_T is +V and the slowest speed occurs when E_T is near V_{TH}.

The duration of the unit timing period, which is equal to the time of a dot or space, is determined as follows: The standard word "PARIS," requires 48 unit periods (dot periods). Therefore, at 30 words per minute (half a word per second) there are 24 unit periods per second and the duration of a unit period is about 0.042 seconds. To produce a dot period of 0.042 seconds requires an RC of 0.029 seconds (0.042 x 0.69). A standard 3:1 dash period is 0.126 seconds and the RC is 0.087 seconds. The dot and space are varied with respect to the dash to change the keying weight. The value of E_T/+V for various keying speeds is given in **Table 1**.

The keyer shown in **Fig. 3a** uses two CMOS ICs: a CD4001 quad NOR gate and a CD4009 hex inverter. U1A and U2A generate the dot pulse, U1B and U2B generate the dash pulse, and U1C and U2C generate the space pulse. The dot period is determined by C2 x (R2 + R3) and E_T; the dash period is determined by C3 x R5 and E_T; the space period is determined by C6 x (R9 + R10) and E_T. The dot pulse or dash pulse is triggered with the positive voltage switched through the key. The voltage on the arm of the key is obtained from the AND formed by D5 and D6. The keying waveform for the gate of Q1 is obtained by ORing the dot and dash pulses. The trigger for the space generator is obtained by differentiating the keying waveform with C5 and R8, and inverting the negative transition with U2E. The keying waveform is inverted by U2D to gate the sidetone generator

Timing Voltage vs. Keying Speed

E_T/ +V	Unit period secs.	Speed
1.000	.042	30
.884	.050	25
.769	.063	20
.667	.083	15
.571	.125	10
.507	.250	5

Table 1.

and AND'd with an output from the space pulse generator with D5 and D6 to produce the voltage for the arm of the key; the diodes D5 and D6 clamp the arm of the key low during the key-down and space period. The arm of the key returns to +V only after the end of the dot/dash and space periods. Therefore, only after the dot/dash/space period ends is there a positive voltage available at the key to provide a trigger or re-trigger for either the dot or dash with a key closure. R7 provides the pull-up for the diode AND and in conjunction with C1 and C4, filters out the spike that can occur during the transition from key-down to the space period. The capacitors C1 and C4 also filter any RF that may be picked up on the leads from the key.

The sidetone oscillator, shown in **Fig. 3b** as U1D and U2F, is an astable multivibrator that oscillates at a frequency determined by R14 and C8. The oscillator is gated "on" when the output of U2D applied to U1D (via point A) is zero. The values of C8 and R14 shown in **Fig. 3b** generate a 720Hz square wave during "key-down." To lower the frequency increase R14 or C8. The output current capability of U2F is in the range of 2 mA which is fine for driving CMOS gates or other high impedance loads, but is inadequate for low impedance loads like phones or a speaker. A simple MPF930 source-follower easily provides 100mW of audio power to an 8 ohm speaker or phones.

For example, the typical MPF930 has a threshold of about 3V gate to source and saturates at 0.2A with a gate to source voltage of about 4V. R15 controls the input voltage to Q2. When the input is 3V or less the source voltage is zero and when the drain current is 0.222A the gate to source required is about 4.2V. With 0.222A flowing in 8 ohms, the voltage across the speaker is about 1.8V. Therefore the peak voltage at the gate must be 1.8 + 4.2 or 6 volts. To obtain 100mW of audio into an 8 ohm speaker or phones requires a power supply of at least 6V. A different speaker resistance or power output would require a different supply voltage. The current drawn from the supply is in the range of 0.25A which warrants an AC powered supply. When the supply voltage is more than 6V, a resistor R16 in series with the speaker will limit the maximum current under full volume. With an 8V supply,

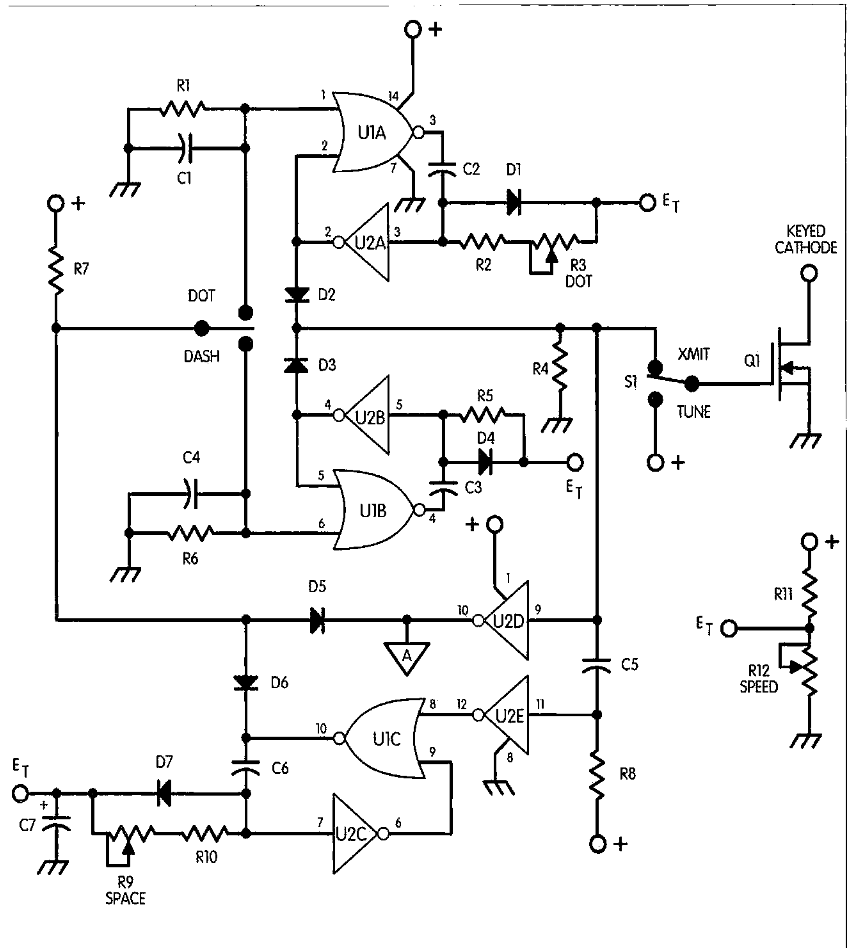

Fig. 3a. The keyer uses garden-variety CMOS ICs.

R16 should be 13 ohms but with a 12V supply, it should be 27 ohms. If the sidetone generator is not desired, delete the parts marked * in **Table 2** and tie the inputs of U1D and U2F to either +V or ground.

The electrical parts list for **Fig. 3a** and **Fig. 3b** is given in **Table 2**. Most of the parts are available from Radio Shack™, and those that are not in the retail catalog will be ordered by most Radio Shack stores from Radio Shack Unlimited. If your cupboard is bare and your local store won't order from Radio Shack Unlimited (RSU), equivalent parts can be obtained from almost any industrial electronics distributor. For example, Digi-Key, PO Box 677, Thief River Falls, MN 56701-0677; toll-free order number is (800) 344-4539.

Keying a solid-state transmitter involves switching a relatively low voltage so the "cathode" switching transistor can be safely located in the keyer. Switching 48 volts or less can be done safely with Q1 in the keyer, but if a vacuum tube final is to be keyed, prudence and safety dictate that Q1 should be located near the cathode of the keyed stage to keep the high voltage out of the keyer and away from the operator.

The choice of Q1 depends on the requirements of the transmitter to be keyed. The MPF930 is a TO-92 N-channel enhancement mode MOSFET that can switch +30 volts. While the drain current is rated as 2A, this specification is not very meaningful because thermal conditions limit the current carrying capacity to something in the range of 0.5A in a 122°F ambient temperature. The MPF960 can switch +60 volts. Either the MPF930 or the 960 will be sufficient to key most solid-state exciters. The drain saturation resistance is about 10 ohms which results in a drain to source voltage of about 0.5V when drain current is 0.5A, and about 0.25V when drain current is 0.25A.

Keying a vacuum tube power amplifier requires the keying transistor to switch voltages sufficient to cut off the tube and be capable of carrying the peak cathode current. A typical kilowatt tube final will be cut-off with +100 volts or so applied to the cathode and cathode peak current will be less than 1A. **Fig. 4** shows how the MOSFET can be used to cathode key a high power amplifier stage. $E_{c/o}$ in **Fig. 4** is a positive voltage sufficient to cut-off the keyed tube for "key-up" conditions, that is, when Q1 is not conducting. Of course, $E_{c/o}$ can be obtained with a resistive divider if need be. The value of the resistor between the cathode and $E_{c/o}$, or Thevenin's equivalent source resistance of the divider, is arbitrary; it must supply the cut-off voltage at zero current during "key-up" and limit the current from $E_{c/o}$ during "key-down."

An N-channel power MOSFET for Q1 is an ideal switch in that drive power is practically nil even though the drive voltage must swing from ground to nearly +10V. The package style essentially determines the power that the device can dissipate without a

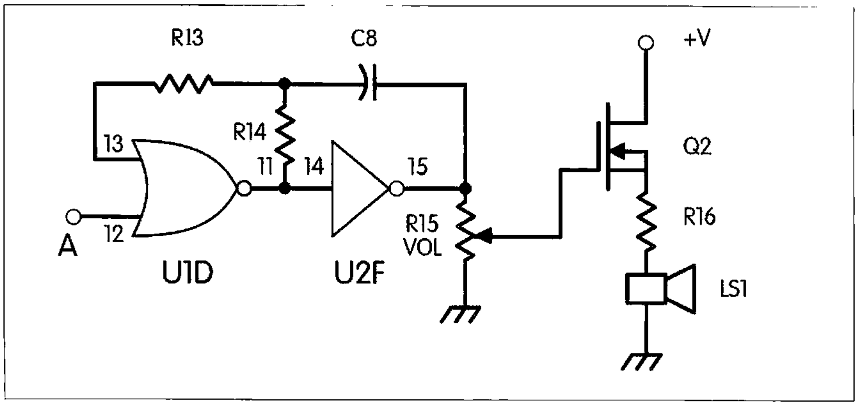

Fig. 3b. The sidetone generator is optional.

Table 2.

heat sink. For example, a TO-220 package has a junction to ambient thermal resistance R_{JA} of 62.5°C/W and the junction temperature must not be allowed to exceed 150°C. When the device dissipates 2 watts the junction temperature rises 125°C above ambient which limits the ambient to 25°C. The temperature near the tube socket of a tube final can approach 100°C. Under these conditions the power dissipation in the switch would have to be limited to 0.4 watts. A heat sink reduces the thermal resistance from case to ambient and since the device's junction to case thermal resistance, R_{JC}, is only few ohms (in the range of 2°C/W), a moderate heat sink can be effective in reducing the junction's temperature rise.

In general, the die size of a device determines the DC current rating and saturated drain resistance, R_{DS}, other conditions being equal. For example, Motorola's MTP2N20 has an R_{DS} of 1.8 ohms, while the MTP5N20 has an R_{DS} of 1 ohm, and the MTP8N20 has an R_{DS} of 0.4 ohm. For a given drain current, the saturated dissipation is directly related to R_{DS}. Therefore, a larger die has lower power dissipation for a given current. A MTP2N20 dissipates 1.8W when the drain current is 1A, the MTP5N20 dissipates 1W, and the MTP8N20 dissipates 0.4 Watts. The junction temperatures for the three devices would be 112.5°, 62.5°, and 25° respectively. Holding the junction temperatures to under 150° limits the operating ambients to 38°C, 87.5°C and 125°C respectively.

It goes without saying that MOSFETs with higher current ratings have larger dice and cost more than the lower current devices. A moderate heat sink similar to Radio Shack P/N 276-1363 with a thermal resistance of 30 ohms is a cost-effective solution to using lower current devices in higher ambients. For example, the MTP2N20 has R_{JC} of 2.5°C/W and with a 30 ohm heat sink the junction temperature rise, when switching 1A, is (30 + 2.5)°C/W x 1.8W = 58.5°C, which means it can operate in an ambient of 91.5°C. The MTP5N20 has R_{JC} of

1.67°C/W and under the same conditions the dissipation is 1W and junction temperature if (30 + 1.67)°C/W x 1W = 31.67°C. With a heat sink, it could operate in an ambient of 118°C.

However, if the cathode current were 2A, the power dissipated in the devices would be four times greater and the heat sink would be more important. Even with a 30 ohm heat sink the junction temperature of the MTP2N20 is an unacceptable 234°C. The MTP5N20's junction temperature would be 126.7°C. The lower R_{DS} of the MTP8N20 results in a dissipation of 1.6W. Its junction temperature rise is (30 + 1.67)°C/W x 1.6W = 50.7° and it can operate in an ambient of 99.3°C.

Clearly, the MTP8N20 is the transistor of choice if the cathode current to be switched is 2A while the MTP5N20 can be used to switch 0.9A in a 102°C ambient. A very thin coat of thermal grease between tab and heat sink is needed to achieve the lowest thermal resistance from case to heat sink. Low thermal resistance is desired because lower junction temperature leads to longer life.

A little less than 8V of gate drive is needed to drive either the MTP5N20 or MTP8N20 into drain saturation with 2A of drain current. Therefore, the keyer power supply should be greater than 8 volts.

The power supply for the keyer is not critical, except that the MOSFET Q1 dictates a minimum voltage of 8V or greater and the CMOS devices limit the maximum voltage to 18V. The current drawn by the keyer without the sidetone is less than 0.1mA and a 9 volt transistor battery has a life expectancy greater than 1000 hours. The current drawn by the sidetone generator is a function of the audio power output. With 100mW output into 8 ohms, the current is 111mA which is best obtained with an AC powered supply.

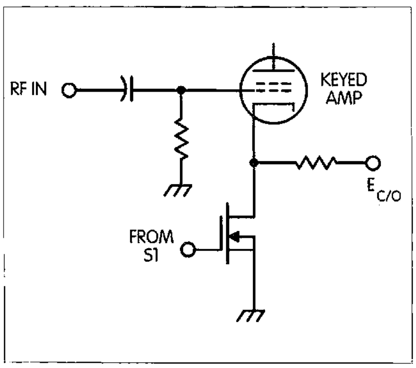

Fig. 4. A power MOSFET can cathode-key a high power RF amplifier.

Adjusting or tuning the transmitter can be done with a string of dots or dashes if the duty cycle is factored into the meter readings, 50% for dots and 75% for dashes. A "Tune" switch, S1 in **Fig. 3a**, allows the transmitter to be operated continuously for tuning and the transmitter's meters to be read directly.

Initial adjustment of the keyer to produce the standard timing—dot and space equal to one unit of time, and dash equal to three units of time—is straight forward. The only test equipment needed is an average-reading voltmeter, either analog or digital. Be aware that not all DVMs read average on the DC ranges. The procedure is as follows:

1. Connect an average-reading DC voltmeter between the drain of the switch transistor, Q1 , and ground.
2. Note the exact indicated voltage when the "Tune" switch, S1, is in the "XMIT" position, and the key is up. The voltmeter will read +V or $E_{c/o}$.
3. With S1 in "XMIT," close the key to the dash position and adjust the "space" trimmer, R9, to make the meter indicate exactly 25% of the voltage measured in Step 2. The meter's needle will flicker if the "Speed" control is set too slow. Set the "Speed" control to get a steady meter reading.
4. Close the key to the dot position and adjust the "dot" trimmer, R3, to make the meter indicate 50% of the voltage measured in Step 2.

That's all there is to it. The "space" trimmer controls the duration of the space relative to the dash period, and the "dot" trimmer controls the duration of the dot relative to the dash period. The dash period is controlled by the "Speed" control, R12 .

The sidetone generator is a separate option that may be used or not; it has no effect on the keyer. It doesn't monitor transmitter output; it only monitors when the key is down and the transmitter *should* be transmitting. If your transmitter doesn't have a built-in sidetone generator, this one can fill the gap.

The keyer is a fine weekend project for the flat-walleted brasspounder and the non-critical components suit the most limited junk box. With the design considerations given, you can modify the circuit to fit the parts at hand. The keyer can make generating the kind of CW you like easy, without spending a lot of money—and it may help clean a few pieces out of the junk box.

NEVER SAY DIE
Continued from page 7

Michigan Miracle is almost worth looking at. The Michigan unemployment rate was above the national average for 192 months in a row (1978-1993). It's been below the national average for the last 28 months and Michigan has been turned from a rust belt to a growth belt state.

The Republicans have eliminated the $1.8 billion debt; balanced the state budget for five years in a row; cut taxes 21 times!; downsized the state bureaucracy, while improving state services; and eliminated a bunch of red tape. For three years the state has led the nation in wage increases. Job creation has been at an all-time high. Michigan has proven that tax cuts not only work; they can work wonders! Now, if we could just get Clinton to try a tax cut. Instead he put through the largest tax hike in the history of the country.

They've reformed welfare, with the result that over 90,000 Michigan families are now on the payroll instead of the welfare roll. And one in three of the Aid to Families with Dependent Children (AFDC) is working as compared to one in 12 nationally.

Those Pesky ETs

There goes Wayne, off his rocker again. Well, some recent books I've read have certainly gotten me on a shuttle to Weirdsville. Unfortunately, since a good deal of it makes sense, I'm going to share it with you.

Unless you've been squatting in a cave somewhere, out of touch with the media, you know about Harvard professor John Mack, who decided to look into the stories of people claiming to have been contacted by aliens. His original intent was to show how this contactee stuff was all some sort of mass hysteria baloney. He ended up, after four years of research, publishing a book (*Abduction*) saying that the phenomenon is real, which immediately made him a pariah with his fellow professors.

If you've read Strieber's *Communion*, and his *Breakthrough*, both of which are tediously dragged out stories which can help you enhance your speed-reading skill, you know that tens of thousands of people have been reporting repeated contacts with ETs, and that most of them don't want to talk about it.

A reader sent me a copy of Dr. Arthur

Horn's *Humanity's Extraterrestrial Origins*, subtitled, "ET Influences on Humanity's Biological and Cultural Evolution." Yes, this sure sounds like another woowoo-weirdo book, based on wild speculation (imagination). Instead I found a very carefully researched and thoroughly referenced book. More about that coming.

Another similar book I read recently was also well researched and annotated. This was Temple's *The Sirius Mystery*. I've written about that recently. But, as carefully done as that was, I found Yin's *Pleidian Perspectives on Human Evolution* to be a waste of time. If you're interested in some solid pyramid research you'll want to get the $14 Bauval & Gilbert paperback, *The Orion Mystery*. And also, Tompkins' *The Secrets of the Great Pyramid,* which is $30 and a big (416p) book. The mystery of how these ancient civilizations suddenly sprung up is also discussed by Hancock in his *Fingerprints of the Gods*. All these books tie together in many ways, and lend support to the conclusions in Horn's book that aliens have been around for thousands to hundreds of thousands of years and have been guiding our biological and social development for their own purposes.

Horn points out that the introduction of many languages and religions has served to keep us at war with each other, thus keeping us busy and more easily controlled. Worse, he goes into details on how the major religions started, and then goes back to the most ancient of texts to support his theories.

Horn's theories also help explain why paleontologists have been unable to find any Darwinian predicted chain of evidence for the beginnings of man. Somehow, we magically appeared, with no signs of intermediate life forms having yet been found. Poof, suddenly there was man!

So, between Horn and his voluminous references, the Strieber books, the contactee stories, the millions of UFO reports, and so on, these theories do help tie together a bunch of evidence which mainstream scientists are doing their best to ignore. "Anomalies" is their explanation.

Being a pragmatist, I tend to go with any theory that helps explain the facts. I try not to get emotionally involved (make it a religious matter), and am open to any other explanations which will also fit all of the facts (and not just ignore them). And Horn does do a good job of sorting out the facts and assembling them into a reasonable theory.

I have no problem with the concept of aliens visiting the earth hundreds of thousands of years ago and doing some biological engineering to provide them with a work force. Or in some aliens still being around behind the scenes, keeping track of and influencing events. Even if you accept the big-bang theory (which I no longer do), the universe is plenty old enough for advanced civilizations to have checked out all habitable planets millions of years ago.

Erich von Däniken wrote about this stuff in the '60s and '70s (*Chariots of the Gods*). As I mentioned a few years ago in an editorial, when von Däniken brought up the subject of the Admiral Piri Riis map and cited a ham friend of mine, Father Linehan W1HWK, the head of the Weston Observatory, as an expert on the map, I visited him to see how well von Däniken had done his homework. I found that the map did indeed show Antarctica as it was without the mile or two of ice on it. Further, as a result of the map, Fr. Linehan made soundings in Greenland, where the map showed it to be two islands, and found the map was right. That was the first time this was known. So where did a map showing an Antarctica and Greenland without ice come from? He said it had been copied from other much, much older maps.

Oh yes, the map is centered from above the pyramids of Egypt. Did you know that the position of Egypt's pyramids and their size is a replication of the stars of Orion and that the "ventilator shafts" in the Giza pyramid pointed toward Orion, Sirius, and the Hyades when it was built?

Well, this stuff is more fun to read about than endless stories of the misdeeds and waste of Congress.

Horn has done a monumental job of researching ancient writings and posits an answer for several major historical changes which have baffled archeologists, such as how man suddenly appeared, with no intermediary life forms having yet been found. And how, after a million years or so as hunter-gatherers, suddenly, in just a few years, man seems to have domesticated plants and animals, making farming possible. Then there was the sudden appearance of towns and cities, which call for major developments in organization.

He also has done a remarkable job of researching the early days of the major religions and explained many things about Christ and Christianity that I never heard in church. This is not stuff that any seriously religious person should read. It's better they don't know.

I liked the way Horn's story ties in with what I've read in several other books on Egypt, the Dogon tribe, Graham Hancock's research, and so on. And Pat Flanagan's work too. He's done a lot of pyramid research. There's a new book out on Flanagan and his inventions by Nick Begich, the chap who wrote the HAARP book, *Toward a New Alchemy*.

Yes, all this flies in the face of what we've been taught in school and church, so perhaps we'll do better if we ignore troublemakers like Horn and believe what we've been taught and can see. Any fool can see that the sun is circling the earth, so no wonder Galileo was given a hard time.

Rejuvenation

A while back an old man was struck by lightning—and survived. It was what happened next that was so surprising. He grew a third set of teeth and a head of new dark bushy hair. His inoperable cancers

Simple Mods for the Ramsey FX Transceiver Kit

Customize it!

Peter A. Bergman NØBLX
3517 Estate Dr. SW
Brainerd MN 56401

For those of you not familiar with the FX series kits from Ramsey, they are 12-channel, diode-programmed, FM transceivers with an output in the neighborhood of 5 watts. The series includes rigs for 6 meters, 2 meters, 220 and 440 MHz. The microphone, case and speaker are optional. The theory and assembly manual is all I could hope for. That's where the germ of some of these modification ideas came from.

Mods? For a kit? Why build in the first place? Scratch builders build for several reasons, including the fact that the device they want may not be available at any price. It may be *available* but not exactly the way they want it, or they may want to create something which is uniquely theirs. I suspect that our primitive ancestor who first decided to keep the thighbone s/he had just used for bashing something may have decorated it for the same reason.

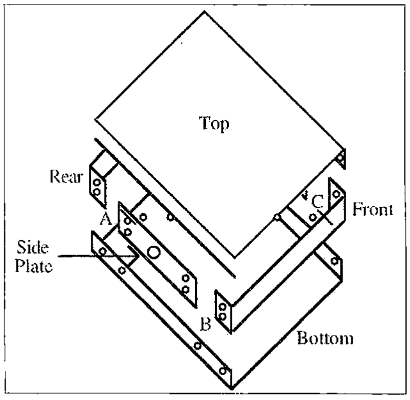

Fig. 1. *Slide switches can be mounted easily at points A, B and C. File notches in the case top to allow free movement of the switch handle. The side plate may need to be shortened slightly.*

Kit building satisfies a large part of that creative urge. Modifying the kit is an even larger step in that direction. Besides, if you built it and it quits working, you have a better chance than almost anyone to make it right again. And it's just plain fun!

On/off indicator

The first change I decided to make to my FX-146 was to install an on/off indicator. I could have wired an LED to the power switch or the wiper of the channel switch but I decided to make it more useful by connecting it to position #1 on the channel selector switch (S2). That's where I've programmed the repeater I monitor 99% of the time. If I see a green light I know that the rig has power and it is tuned to the local repeater. I installed a bi-color LED and connected the other half to position #12, where I've programmed the CAP repeater. Now I have an LED indication that shows if I'm on channel 1 or channel 12. I can count clicks in either direction and know what frequency I'm on—even in the dark, while driving.

A handi-ham suggested that it would be nice if the rig beeped at channel one. I haven't done that to mine yet, but it sounds like a good idea so I might implement that mod in the future.

Reverse polarity protection

The FX kit, as I received it, does include reverse polarity protection. An easy way to provide that protection in a kit or other project is to install a nice hefty power diode backwards between the positive line and ground. When power is connected properly—negative line to ground—the diode will look like a very high impedance—an "open"—and have little or no effect. But, if the leads are reversed at the power source the diode will look like a short and blow the fuse before any damage is done to the rig.

In the December 1994 issue of *73*, Frank Kamp K5DKZ describes another method of reverse polarity protection using a bridge rectifier. If you use his method it doesn't matter how you apply power as the bridge insures correct polarity. Cheap insurance either way.

Non-standard splits

When I bought my FX kit I was assured that it could be programmed for the Civil Air Patrol repeater frequency pair. So when I got to the programming phase of construction I put in 146.52 like the book said. Then I installed the programming diodes for the local ham repeater. So far so good. Then I put in the CAP output frequency of 148.15. Fine. I could hear the repeater. Then I went to the auxiliary line on the matrix and tried to put in the 4.25 MHz split. After considerable study—and hair pulling—I decided that I could get close but not close enough. A couple of phone calls to Ramsey later I'd learned two things. The auxiliary line in the matrix was not set up to be programmed for 4,250 kHz or any other split that could not be divided evenly by eight. And the bits I needed to program that split were there but they were soldered to both sides of the plated-through board at U10, one of the 74HC283s.

A number of alternatives suggested themselves to me but I settled on the cheapest. I used a needle-point jeweler's file to cut pins 6, 2 and 15 loose from the board. They are, respectively, 1, 2 and 4 bits. Then each pin can be tied above ground with a 100k resistor and programming diodes run from each pin to the auxiliary line as needed for your application. It's kind of a combination of the worst aspects of "ugly construction" but mine has been that way for two years and still works fine. If you are absolutely certain that you will never ever want to install a non-standard split just solder U10 to the board. If you think you might, then socket the durned thing so you can get to the pins later.

Access tones

Most Civil Air Patrol repeaters share one frequency pair and require a CTCSS tone for access. I had decided to try using another Ramsey kit, the TD-1 Tone Decoder-Encoder, to generate the access tone for our local CAP repeater.

The TD-1 Tone Decoder-Encoder is a fun little kit all by itself. The board is not much bigger than an Elvis commemorative stamp and only takes a few minutes to assemble, but it comes with a 16-page manual that explains a lot about CTCSS and DTMF tones and gives some ideas about everyday control applications.

All I had to do to get the TD-1 to work for me in the FX transceiver was to add a one-transistor buffer stage and level pot to the basic kit, as explained in the TD-1 manual. Connecting it to the transceiver was a piece of cake since Ramsey plainly marks the points for "PL" input and various points on the transceiver board where I could get the 8 volts to run the tone board.

This gives me one tone which I can turn on and off with a little slide switch. But what if I want more tones? The frequency of the TD-1 is set with a precision pot. How about installing a little sub-board with two or three pots and a front panel switch to select the tones? No, it won't give me access to all the CTCSS tones, but I don't travel much anyway. Ramsey does have a new kit, the QT-1 Subaudible Tone Encoder/Decoder. I've not had a chance to try it out but it is very small and does generate any of the CTCSS tones via switch settings.

You could also hook up a TD-1 as a tone decoder. Then when it is turned on, your receiver would be silenced until someone transmitted that tone. Hmmm. A private line. Wonder what we should call it?

If you are concerned about running out of room on the front panel look around and see if you can find a pair of concentric shaft pots—with an SPST switch. Then you could gang the on/off, volume and squelch controls. That should help make more room for your modifications.

Out-of-band operation

All of the FX rigs are capable of operation outside of the ham bands, where you do not want to transmit without the proper license. A flashing LED installed in the front panel—or wherever you want it—and wired to the appropriate channel-switch position will help you avoid embarrassing little incidents. And visits from the FCC or X-Files. You could make it beep there too.

Channel expansion

When I ordered my FX kit, one of my concerns was that it has "only" 12 channels, so once I had it working, I just had to try expanding it. The method I was looking for had to be cheap—excuse me—thrifty, and fit into the rig with minimum fuss and no external parts. I've seen plans for an interface that allows the user to control the frequency with an external computer and there is a kit available now that moves programming to the front panel, but I wanted thrifty *my way*.

The local club operates a weekly emergency services/test net on the repeater output; if the machine quits we'll know where to meet and what kind of coverage to expect. In fact, once, about 30 seconds into a Skywarn Net the repeater took a lightning hit and went off the air, so I knew I wanted 147.03 simplex, but I did not want to tie up one of my precious 12 channels for it.

Once you have programmed a frequency you have to decide if it is going to be +rpt, -rpt or simplex by installing a diode on the matrix at one of those positions. I installed the diode on the wiper of a double throw switch and ran wires from the contacts of the switch to +rpt and simplex.

I knew before I started that I wanted to program 146.73 and 146.76, and when I looked in the book I saw that both frequencies used the same number of diodes with only one of them being in a different position. I decided that I could use the same switching idea to put two repeater pairs on one channel position. All very elementary to this point, but where do we put this growing number of switches without creating a monster we can't use without accidentally bumping things? The solution turned out to be so simple that I've wondered if Ramsey planned it that way.

If you look at **Fig. 1** you'll see that the Ramsey case is a six-piece clamshell design. In each corner where the pieces come together there is room, with a minimum of metalwork, to install a slide switch. The switches, standard size medium duty DPDT, required a minimum of trimming and filing to fit the case. The mounting ears on the switches are clamped between the case bottom and inner plate and either the front or rear panel mounting ears. This mounting method is very solid and has really stood the test of time here.

You probably won't want to install any accessory switches in the right rear corner near the antenna connector. If you do you might end up feeding RF to some part of the rig that really isn't ready for it and it's hard to predict what the presence of extraneous leads in and around the final will do to your output.

Antenna connector

I'm one of those guys who really doesn't care to use connector adapters. They usually add a bit of attenuation and frequently get lost. So install a BNC connector next to the stock SO239 and wire them in parallel. There is plenty of room and it shouldn't hurt anything.

Conclusion

Naturally, before you install these mods, or any others, it makes sense to make sure the device works the way it's supposed to. If you have absolutely no experience in building there are a number of inexpensive kits that will help you get started. Give it a try.

Both of the kits mentioned above are available from Ramsey Electronics, Inc., 793 Canning Pkwy, Victor NY 14564; phone (716) 924-4560.

Build This Receiver Preamplifier

... and use almost anything for an antenna.

Stephen James Erst W9QHV
17516 SE 96th Court
Summerfield FL 34491

What's happening on the 49 meter band? Is 15 meters open? How about 10? Want to look for beacons on 200 kHz?

If you are like most of us, you don't have antennas for every band. If you are an SWL you probably would like to cover frequencies from 200 kHz to 30 MHz or more, and a half-wave antenna at 200 kHz is almost half a mile long. Don't despair, there is a solution: a high input impedance preamplifier. The preamplifier must have a reasonably high input impedance for random wires, either vertical or horizontal, and a low output impedance to drive today's 50 ohm input impedance receivers, and it must have an adjustable gain from 1 to 20 dB.

Here is a preamplifier that lets you use a short antenna over the range from 100 kHz to well over 55 MHz, with excellent sensitivity. Using a vertical 30-inch piece of number 12 wire, or a few feet of wire laying on the floor, signals which had been barely moving the S-meter were 10 to 20 dB over S9 using the preamplifier, even at 200 kHz.

Construction

This preamplifier can be easily constructed in a few hours, and this will be time well spent. The design utilizes two transistors in a complimentary configuration with feedback to broaden the frequency response and provide the needed, low output impedance.

Fig. 1 illustrates the configuration. Transistor Q1 (NPN) in directly coupled to PNP transistor Q2. Feedback from the collector of Q2 to the emitter of Q1 is accomplished by resistors RF and RA. Because of the high open loop gain of the amplifier the gain of the amplifier is RF/RA, or 20 dB maximum. A 1k potentiometer changes the effective value of RA, resulting in a minimum gain of near unity.

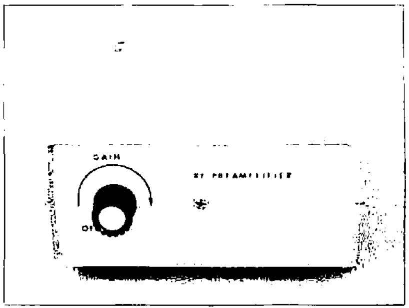

Photo A*. The completed preamplifier unit.*

The amplifier is constructed using a Radio Shack™ perfboard, and is relatively simple. Because of the wideband nature of this amplifier care should be exercised to prevent ground loops, which will cause oscillation. This should be checked using a detector on the output with no signal input. There should not be any detector output with no input signal. A detector configuration suitable for this purpose is shown in **Fig. 2**. Input terminals are provided for coax or a wire antenna and the output uses a BNC connector to connect to the receiver.

The amplifier may use almost any complimentary pair of transistors. I used a 2N3904 for Q1 and a 2N3906 for Q2. If wider bandwidth is desired, a 2N918 and a 2N3546 may be used. Another combination is a 2N2222 and a 2N2907. The pinout for the transistors used is shown in **Fig. 3**.

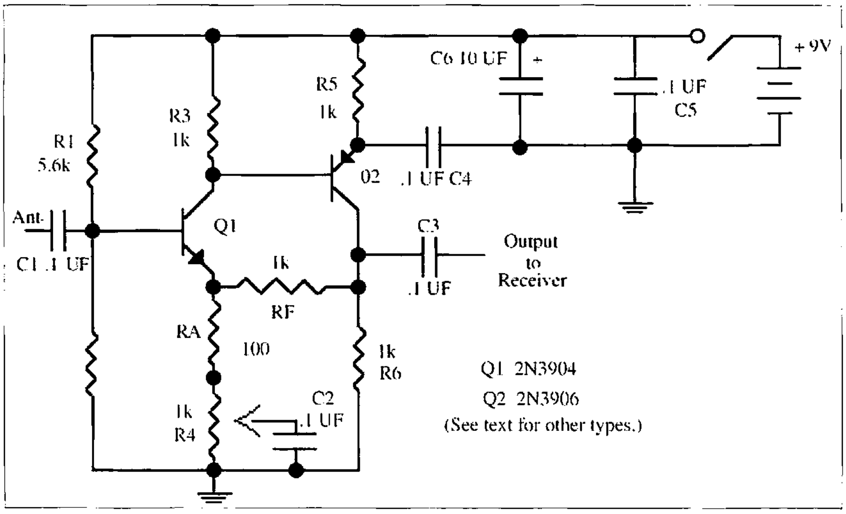

Fig. 1*. Preamplifier schematic.*

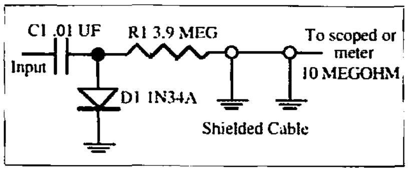

Fig. 2. Detector for checking if the preamplifier is oscillating.

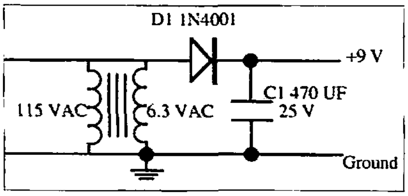

Fig. 4. Suggested AC power supply.

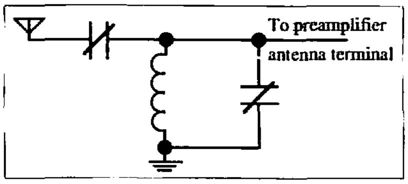

Fig. 5. Preselector for the preamplifier if spurious response and intermodulation are problems. Parts values vary depending on the band.

The 1k gain control may use Radio Shack's 5k potentiometer shunted by 1,250 ohms made up from a 1k resistor in series with 250 ohms. An on/off switch should be used to disconnect the battery.

The operating voltage may be provided by a 9 volt battery or by an AC power supply consisting of a transformer, rectifier and filter capacitor. Regulation is not necessary. A typical power supply is shown in **Fig. 4**.

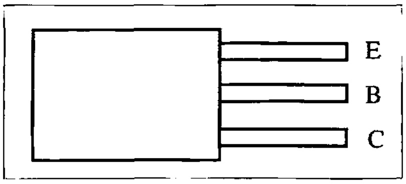

Fig. 3. Pinout of the 2N3904 and 2N3906 transistors.

Because of the broad bandwidth and the high gain of this preamplifier some receivers may be prone to intermodulation distortion and poor spurious frequency rejection due to signal overload. If you experience such problems, reduce the antenna size or preamplifier gain. If you still experience problems, preamplifier preselection may be necessary. To maintain the high impedance of the preamplifier a simple parallel-tuned network with capacity coupling to the antenna may be used. One such network is shown in **Fig. 5**.

The performance of this preamplifier is impressive because of its low output impedance and high input impedance. This project can be completed in a few hours from the junk box or from parts readily available from Radio Shack. Hook it up to a chunk of wire or whatever you have for an antenna and check it out.

Parts List

R1, R2	5.6k
R3, R5, R6, RF	1k
RA	100
R4* (see note)	1k potentiometer, with switch
C1, C2, C3, C4, C5	0.1 µF capacitor
C6	10.0 µF capacitor
Q1	2N3904
Q2	2N3906
9 volt battery	

*Note: A Radio Shack 5k potentiometer may be used, shunted by 1k in series with 250 ohms.

Rechargeable Batteries

The bottom line.

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

The rechargeable battery business is booming today. With the wide-ranging market in amateur radio and business-band portable transceivers (HTs), the portable miniature cellular phone explosion, and now portable laptop and notebook computer systems, rechargeable batteries are found in many more areas of life than ever before. Understanding something about these batteries and their technology has also become increasingly important, so here's a brief primer in easy-to-understand terms.

Mr. Wizard stuff

All batteries work on a similar principle: Current flow between a negatively-charged metallic plate and a positively-charged metallic plate is stimulated by a highly ionized electrolyte, such as an acid. Even a lemon, with its naturally acidic juice, will act as a battery when two plates of dissimilar metallic composition are placed within it. Do you suppose that's where the term "juice" comes from?

Back in the old days

For decades, the only practical rechargeable battery was the lead-acid battery, primarily used in automobiles, boats and airplanes as a storage medium for electrical power. The vehicle's engine, when running, can drive a generator or alternator for recharging the lead-acid battery. Then, about 30 years ago, nickel-cadmium rechargeables came onto the scene and took up some of the market share for portable electronic devices of the time (larger "wet" NiCds were also used in stationary battery back-up applications, but were costly). Lead-acid batteries soon challenged NiCds' dominance in the portable electronics field with a "gelled electrolyte" version. Both battery technologies have had their successes and drawbacks in portable electronics since that time. At present, we also have two newer battery technologies struggling for our attention: nickel-metal-hydride (NiMH) and a rechargeable lithium formulation. Let's take a brief look at all four competing formulations.

Boring definitions

First, a couple of definitions. A "cell" is the basic unit. A number of cells are connected in series so that their combined contributions add together. So a battery's cell is just one unit, and the battery itself is a number of those cells connected in series-additive form. Even though we ordinarily call a flashlight cell a battery, that's not technically correct—you need two or more cells in series to make up a "battery" of cells.

Lead-acid cells

Let's look first at the lead-acid cell formulation. The biggest advantage of lead-acid cells is cost; they're relatively inexpensive to manufacture. Lead-acid cells also can be easily kept up to snuff, charge-wise, with a constant voltage charger, with no ill effects. In fact, they rather prefer that kind of treatment. On the disadvantage side of the coin, however, lead-acid cells are heavy. They have the poorest weight-to-energy ratio of all the battery formulations; lead is heavy stuff! The acid used in lead-acid cells (sulfuric acid) is noxious and corrosive if spilled or if accidental leakage occurs. Other formulations aren't as immediately destructive as sulfuric acid; it can be nasty! Eventually the lead plates in a lead-acid battery become clogged or nonporous (technically called "sulfated") and the cell is no longer rechargeable. Lead-acid cells are usually rated for 500 or more recharges before this happens, but it's also predictable on a time-from-manufacture basis. The "spongy lead" in lead-acid batteries has to be beefed up with the addition of antimony (a brittle, white-colored base metal). Antimony reacts with the acid and eventually contaminates the "spongy lead," so lead-acid cells have a built-in clock once the acid is introduced. When that clock runs out, the cell is unsalvageable. A Happy Motoring Tip: Best not to "push" your car battery too much beyond its life-in-years rating printed on the case.

NiCd cells

Nickel-cadmium cells, on the other hand, have a much better weight-to-energy output ratio than do lead-acid cells. This can be very important to users of today's miniature electronic devices, but these batteries are also more expensive to make. NiCds maintain a relatively constant output voltage as they discharge, whereas lead-acid cells drop off (voltage-wise) more linearly. But NiCds also have a "memory effect" attributed to them. One manifestation of this "memory effect" is when NiCd cells are kept on constant charge: They tend not to deliver their full potential charge unless they're first fully discharged. The way this oddity in NiCds shows up goes something like this: When a NiCd cell is fully charged, its open terminal voltage is about 1.4 volts. As the battery's reserve is drawn upon by the load, that figure drops fairly quickly to 1.3 volts, then to 1.2 volts. The NiCd cell maintains that 1.2 volt level right up to the end of its useful discharge curve, at which point it drops quickly down to 1.1 volts, and then lower... all the way to zero. When that 1.1 volt point is reached the load should be removed, because further discharge can harm the pack. In any pack of six, eight or 10 cells, one or two cells will always hit bottom first, and if the load is

still connected to the pack, current in the reverse direction will be forced through the bottomed-out cells, causing them to reverse polarity. They're usually not salvageable after that happens. Since the drop from 1.1 volts per cell is rapid, "smart" devices will automatically shut down at the point of 1.1 volts per cell, saving the pack from potential harm. The memory quirk mentioned before, however, causes the fast drop-down to occur at a somewhat higher terminal potential than 1.1 volts per cell, so it can be a fooler. The pack (battery of cells) becomes "trained" to expect recharging at a higher point in its discharge curve, and therefore won't deliver as much energy to the load before it "wants" recharging. It's shaken back into reality by one or two deep discharges, carefully monitored so that cell reversal doesn't accidentally occur. So remember that NiCds can become "spoiled" by over-feeding, but it's usually a correctable mistake, even though it's somewhat inconvenient.

It's best to charge NiCds slowly, over 16 to 18 hours, but rapid charging is possible if the cells are built to take the extra punishment. Heat is the enemy of NiCds, and rapid charging causes heat buildup within the cell—it's a sign that the chemical reaction of recharging is taking place too quickly for the cell to handle properly. Rapid charging generally reduces the pack's useful life by 50% or so, about the same as that of a lead-acid battery. It's often an acceptable price for the convenience of rapidly recharging when that option is valuable to the user. When the pack reaches full charge after being rapid charged, a slight discharge can be detected and the rapid-charging turned down to a trickle charge (hopefully).

NiMH cells

A newer alternative to NiCd chemistry is NiMH, or nickel-metal-hydride. NiMH cells have about the same energy-to-weight ratio as do NiCds, but NiMH cells have a much greater energy-to-volume (physical size) ratio—about 25% more. This means that a NiMH cell can be the same physical size (even though somewhat heavier) as a NiCd, and will deliver 25% more energy per charge. NiMH is also more "environmentally friendly" and is sometimes called the "green rechargeable cell." NiMH cells can be charged more quickly than NiCds without loss of potential recharge cycles. They can stand more heat buildup, and, in fact, normally get hotter during recharge than their NiCd counterparts—but that's normal for the NiMH chemistry. They also don't exhibit as much "memory effect" as NiCds do, but there is still some memory retention. The "normal" output voltage per cell is 1.2 volts, just like a NiCd cell. The number of charge/discharge cycles for the NiMH chemistry is about the same as for lead-acid and rapidly-charged NiCds; about 500. They're a bit more expensive to produce than NiCds right now, but the price will no doubt drop as more companies gear up for their production and the NiMH market-share increases.

Rechargeable lithium cells

The highest energy-to-weight power density of all of the formulations is found in the fourth and final formulation, the rechargeable lithium cell. Lithium rechargeables can pack double the energy (in terms of both volume and weight) of NiCds. The specially formulated lithium compound used in lithium rechargeables produces an open terminal voltage of about 3.5 volts per cell. Lithium rechargeables are quite new, and therefore the most expensive to produce, for the moment. Manufacturers are also having problems producing rechargeable lithiums in multi-cell packages, but that also may be a temporary drawback. Lithiums are the most "environmentally friendly" of the lot and they have no "memory effect" at all. Rechargeable lithiums seem to be the technology to watch in the next few years for rechargeable-battery-operated gear.

Non-rechargeable alkaline cells

Just as a comparison: The non-rechargeable alkaline cells that we're all familiar with produce 1.5 volts per cell. Their energy-to-weight ratio is roughly double that of the heaviest of the rechargeables, the lead-acid cell, and about the same as that of a NiCd. Their energy-to-volume ratio (energy to physical size), however, is about the same as lead-acid chemistry, so they're much worse in that respect than NiCds, NiMHs or lithiums (just an interesting aside).

A Positive and Negative Power Supply

A simple one-evening project.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30, c/o Defendini
Salinas PR 00751-0030

Many circuits using operational amplifiers (op amps) require both positive and negative voltages to operate correctly. This is quite common, especially in many direct conversion receivers, active audio filters, function generator circuits, etc. Most commercial power supplies produce only positive voltages, usually just +13.8 VDC, so you're going to need a simple power supply to solve this problem.

Some hams solve it by connecting two 9 volt batteries in series with the connection between them becoming the common, usually ground, terminal. While this does produce ±9 volts, these batteries are not only expensive, but have to be replaced periodically. When something stops working right how long will it take you to find it's a pooped-out battery?

The simple power supply described here produces not one, but two different positive and negative voltages, and requires only eight inexpensive components in addition to the small power transformer. The total cost should be no more that what you would pay for one or two pairs of 9 volt alkaline batteries, and can probably be constructed entirely from the contents of your junk box.

Because most circuits requiring split positive and negative voltages draw very little current, and usually do not require specific voltage levels as long as the voltages supplied are within device specifications, simple rectifier/filter circuits providing unregulated output voltages can normally be used satisfactorily. However, where specific voltages are required, such as +12 and -5 volts, small 100 mA three-terminal regulators can easily be added to the basic circuit.

The circuit

The basic circuit for this dual, split-voltage power supply is illustrated in **Fig. 1**. The addition of regulators, if required, is illustrated in **Fig. 2**.

A small power transformer with a center-tapped secondary is required if two sets of output voltages are required. If only a single pair of positive and negative voltages are needed, no center-tapped secondary is needed. If you use a center-tapped transformer, you can use either half, both halves

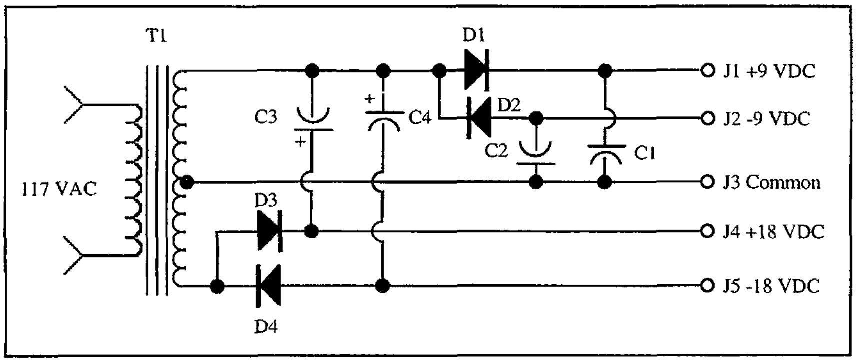

Fig. 1. Unregulated power supply schematic. All capacitors are 1000 μF, 25 WVDC. All diodes are 1N4001 or equivalent.

separately, or the full secondary, depending upon the needs of the circuits to be powered.

The basic circuit uses four half-wave diode rectifiers and four filter capacitors, and will produce two sets of positive and negative voltages. One, using the full secondary, is twice that of the other, which uses only half the secondary. This provides considerable leeway in selecting a suitable voltage pair. It also allows regulating either or both voltage pairs, using the small 78LOxx and 79LOxx regulators.

Terminal J3 is common to both voltage pairs, and although normally connected to ground, it can be left floating if you want. However, it must be connected to the "common" in the circuit being powered.

The voltages given in **Fig. 1** are nominal voltages derived from using a 12 VAC center-tapped secondary of transformer T1. J1 (positive) and J2 (negative) provide ±9 VDC referenced to J3, common. Likewise, J4 (positive) and J5 (negative) provide ±18 VDC referenced to J3.

"It's almost impossible to wire this circuit wrong—but Murphy's always lurking nearby."

These voltage are nominal, with no load current being applied, and with 115 VAC applied to the primary of T1. There may be slight variations from these nominal values measured from your supply.

Construction

There is nothing critical in lead lengths nor component placement. It can be constructed in any type enclosure, or even on a breadboard, but watch out for the AC input terminals. You can build it into the equipment in which it will be used. You may also eliminate T1 by building it into your station power supply, using its power transformer for a source of low voltage AC to the rectifier/filter circuits. However, if the station power supply incorporates a bridge rectifier this may not be possible because of potential voltage differences between power supply negative, and common in this circuit.

Be absolutely certain you observe the polarities of diodes and filter capacitors, and double-check these before applying power to T1. A filter capacitor connected backwards can destroy its associated diode, and can also explode! An incorrectly installed diode will apply reverse voltage to its associated filter capacitor, with similar fireworks.

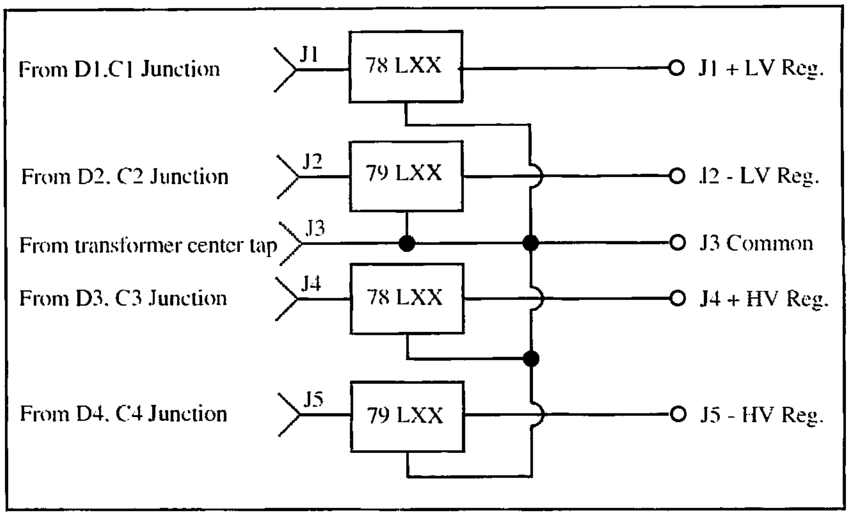

Fig. 2. Adding three-terminal regulators to the basic supply circuit.

Also note the connections to the 78LOxx and 79LOxx regulators, which are different from each other, if these are needed in your application.

Although not shown in **Fig. 2**, you may wish to bypass inputs and outputs of each regulator to enhance stability and to eliminate any hash impressed on the DC voltage rails by the circuits being powered, which could interfere with proper regulation. In this application, 0.1 µF bypass capacitors should be sufficient.

Remember to return J3 common, to which the bypass capacitors are returned, to the common in the externally powered circuit. Usually this will be the DC ground, in which case the bypass capacitors should be returned to the nearby chassis ground, as would J3.

Although the example illustrated in this article provides a nominal ±9 VDC and ±18 VDC, which should suffice for most circuits requiring a split voltage supply, a center-tapped secondary of 24 VAC will produce nominal ±18 and ±36 VDC.

Caution

A transformer supplying more than 12 VAC will produce peak voltages exceeding the diode peak inverse voltages and capacitor working voltage of those specified. In this case, substitute components which will withstand higher voltages.

Because circuits requiring split voltages for proper operation draw only a few milliamperes normally, a very small and inexpensive power transformer can be used for T1. A transformer with a 12 VAC center-tapped secondary rated at 100 mA or more should be sufficient. Just be sure the secondary is center-tapped if you want two sets of split voltages.

Here is a rule of thumb which, if applied in every case, will save a lot of problems in the future: Every time a supply voltage enters or exits an enclosure, bypass inside the enclosure, using a 0.001 µF, 0.1 µF and 10 µF electrolytic capacitor in parallel. These capacitors, acting in concert, will strip the DC lines of any hash generated within or external to each enclosure.

Operation

Check the voltages between J3 and all output terminals before using the supply to power other circuits. Although it is almost impossible to make a wiring error in a circuit this simple if care is taken to correctly orient the diodes and capacitors with respect to their polarities, Murphy is always lurking nearby. So be *sure* before you apply power.

If the four voltages and polarities measured are not similar to those given here, turn it off and see what you've done wrong. Look for poor solder connections and reversed polarities. Replace any components installed in reverse with new ones, just to be sure since they may have been damaged. Feel the diodes, if they are warm look

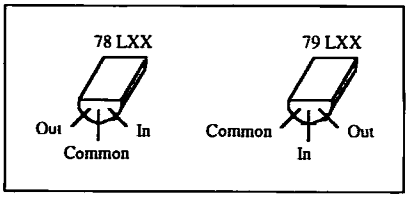

***Fig. 3.** Pinouts for the common positive and negative low current regulators.*

for possible shorts. The associated filter capacitor might be leaky and need to be replaced. Check also for any shorts to common.

If you do not regulate the output voltages, you may notice that there is a slight difference between the voltage levels in the pair being used. This is normal and reflects the different current requirements of the circuit being powered. If the circuit functions correctly don't worry about the voltage differential, which is usually of no consequence. But if it really bothers your sense of perfection, add regulators.

When adding regulators, remember that they require head space—higher input voltages than the desired output voltages. The 9 VDC rails can be regulated to 6 volts or less, and the 18 VDC rails can be regulated at 12 volts or less, and possibly even at 15 volts in most supplies.

You may be tempted to use zener diodes as regulators. I don't recommended this because they will cause additional current drain, and the diode and its dropping resistor have to be matched to the current required by the external circuit. This limits the universality of uses for which this power supply was designed. 73

Parts List

C1-4	1,000 µF 25W VDC (minimum) electrolytic capacitor
D1-4	Rectifier diodes; 1N4001 or equivalent
J1-4	Terminals, your choice
T1	Transformer, 120 VAC to 12 VAC center-tapped, 10 mA or greater

NEVER SAY DIE

Continued from page 23

disappeared. He no longer needed his glasses or cane and was completely healthy and looked years younger, much to the bewilderment of the doctors who followed and documented his progress.

It may be that the doctors at the Albert Einstein College of Medicine in New York have accidentally tapped into this fountain of youth in their AIDS research. They've patented the process, as have several other hospitals, but there's no word in the medical literature (or the press) of these hospitals using this blood purification system to cure AIDS. One might wonder why the silence. Well, that would be someone who has not done his homework and read about a long string of other remarkable discoveries which have been given a similar treatment by the medical industry.

Are the growing number of miracle cure reports from people using the Miller Bioelectrifier or the Beck "plant growth stimulator" true? Is this simple, inexpensive, and fairly fast process really curing virtually every cancer case it's been tried on? Is it curing AIDS? Lupus, Lyme Disease, and a host of other illnesses? Is it really causing people to lose weight and grow new hair? Is it giving them industrial-strength immune systems which are able to fight off colds, flu, and anything else "going around?" That's what the medical review board reports are showing. How soon will we be able to see some research hospitals fight off the pressures from the AMA and give this approach a rigorous test on Alzheimer's, cancer, osteoporosis, arthritis, diabetes, and so on? Is the Department of Health totally anesthetized?

For that matter, considering the potential, have you heard one single politician say word one about this medical discovery? They don't dare without jeopardizing their lobbying money from the AMA, the doctors and nurses organizations, the hospitals, drug manufacturers, and the insurance industry. The higher our medical costs, the bigger the insurance company buildings and hospitals will grow.

Why am I not surprised, considering the corruption in every industry I've gotten to know personally or read much about? The amazing thing would be if the $1.5 trillion medical industry weren't corrupt.

Cesspool

Gee, I hate to bother you about this, but our 20m cesspool on 14,313 is alive and stinking. Yes, I wasted some time listening to one of our biggest public advertisements for the elimination of our hobby. There was one old man on there with a strong signal, prattling on endlessly about showing Saddam Hussein a lesson. He was cursing freely and showed no indication that thought had contributed anything to his opinions. Other strong voices were breaking

HFx from Pacific Sierra Research Corporation

New propagation forecasting software.

Richard Lubash N1VXW
rlubash@poco.mv.com

As I start writing this review it has been 36 days without a single spot being sighted on the face of the sun. The last time old Sol had such a long period without blemishes was 1944, two years before I was born. We are indeed in the midst of the solar doldrums. At a time like this, a little magic or a crystal ball sure would come in handy—just that extra edge so you could find that lone DX station up on 20 meters that hasn't shown up on the cluster. With so many bands and so little time, it sure would be nice to know where to look. Or maybe you have a buddy in Shiprock, New Mexico, and would like to set up a sked on 17 meters but due to low flux levels haven't been very successful. Well, what you need is some good propagation software for that computer sitting on your bench waiting to log a contact.

Pacific Sierra Research Corporation, out of Santa Monica, California, thinks they may have the answer for you with their new propagation forecasting software, HFx. I know, you think "propagation software" and your mind pictures arcane DOS programs that governments use to find out just when to flood an unsuspecting country with shortwave broadcasts or get that super-secret message through. There are a number of these programs floating around and the key phrase for them is *not* intuitive. Well, HFx is a Windows-based application that is designed around the concept of point-and-click. Out of the box I found myself being able to play around with HFx, though it's true power can't be unleashed until you read the well-written manual.

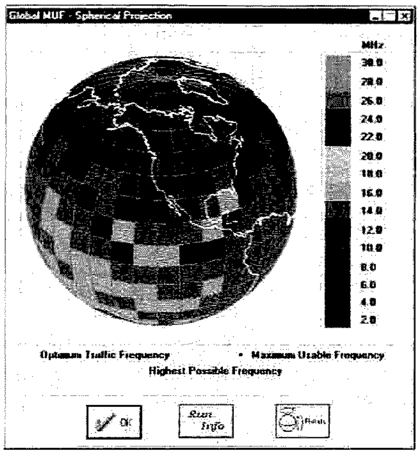

Fig. 1b. Spherical global view of Maximum Usable Frequencies for transmitter location, date and time. This view can be rotated on either axis.

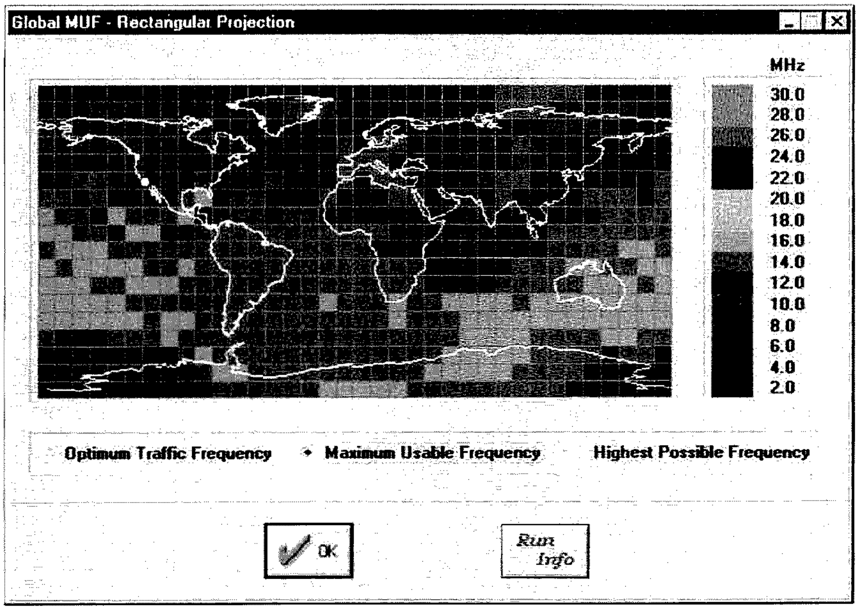

Fig. 1a. World view showing Maximum Usable Frequencies for transmitter location, date and time.

What is HFx?

HFx is a powerful HF propagation tool that calculates ionospheric skywave signal strength from 2 to 30 MHz. HFx uses a very intuitive graphical user interface that heavily supports point-and-click and bases its operation on virtual-raytrace algorithms developed by ITS and CCIR over the last 30 years. The software creates three distinct output models designed around user input of:

- The geographic position of both transmitter and receiver
- Emission power and antenna characteristics
- Date and time
- Propagation path (long or short)
- Solar flux or sunspot number and K index

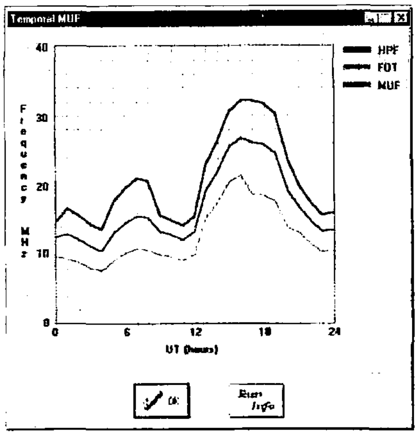

Fig. 2. Highest Possible Frequency, Maximum Usable Frequency and Optimum Traffic Frequency plotted between transmitter and receiver for a 24-hour period.

After you input the above information via dialog boxes or by point and click on a world map, HFx will give you the following models:

•Global MUF, which is displayed by user choice on a flat or spherical world map that can be configured for Highest Possible Frequency, Maximum Usable Frequency or Optimum Traffic Frequency. (See **Figs. 1a** and **1b.**)

•Temporal MUF, which consists of a 24-hour graph plotted for a path between the transmitting station and receiving station with frequency versus UTC time for Highest Possible Frequency, Maximum Usable Frequency or Optimum Traffic Frequency. (See **Fig. 2.**)

•Hop Mode, which provides both a graphic representation of the hop path between transmitter and receiver, and a plot of availability and signal-to-noise ratio for the HF amateur bands 80-10 meters during a 24-hour period. (See **Figs. 3, 4** and **5.**)

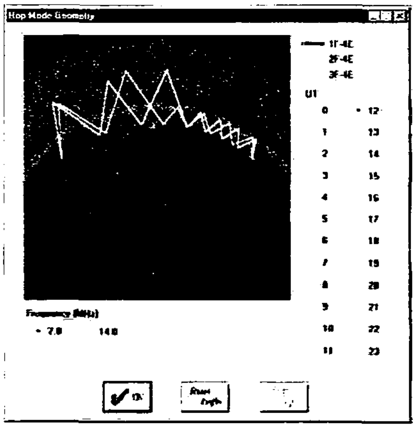

Fig. 3. Hop path for transmitter and receiver on 40 meters at 1200 UTC.

HFx system requirements are a little more robust than the typical hamfest junker PC, but with many hams upgrading their systems running it should not prove too great a challenge. Minimum configuration is:

386-based PC
Windows 3.1 or higher, including Windows 95
Hard drive with 6 megabytes of free space
3.5" floppy drive
4 megabytes of free RAM
Mouse
SVGA monitor set to 256 colors at 640 x 480

> ***"HFx is a powerful HF propagation tool that calculates ionospheric skywave signal strength from 2 to 30 MHz."***

Operation

The main operational window consists of a world map and two tool bars which provide access to all of the features incorporated in HFx (see **Fig. 6**). The map can be configured to show transmitting and receiving station placement, solar position, major world cities, great circle path between Tx and Rx, auroral boundaries based on geomagnetic activity and day/night terminator. The window can be resized via the mouse and the world view will automatically resize to the new window position with no need for scrolling. The system comes with an extensive online help system that mimics the well-written and illustrated manual. Political and state boundaries are not shown on the world map but dialog boxes allow entry via a scrollable list of call prefixes so that placing the transmitter and receiver can be accomplished without the aid of a world atlas.

After playing with HFx for a few hours you can enter data and get results in a matter of seconds, and it becomes fun to see what the software says about the possibilities for the QSO you are currently having. I decided to give HFx a shakedown by comparing its predictions with the actual contacts being made during the '96 CQWW RTTY and CQWW SSB contests. I decided to not only test it against stations that I heard from my QTH but also against station sightings that came in on the DX cluster during the contest. I was able to set up the transmit locations on cluster spots using the latitude and longitude information from a callsign CD ROM, and used the scrollable list of callsign prefixes on HFx for the DX station location. In addition, I used HFx to set up a number of skeds with stations here in the US based on optimal times predicted by the software.

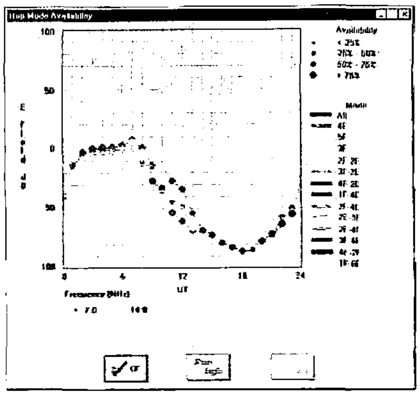

Fig. 4. Hop mode availability for transmitter and receiver on 40 meters over a 24-hour period.

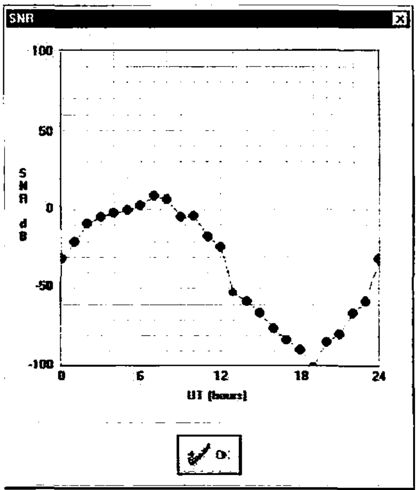

Fig. 5. Signal-to-noise ratio for transmitter and receiver on 40 meters over a 24-hour period.

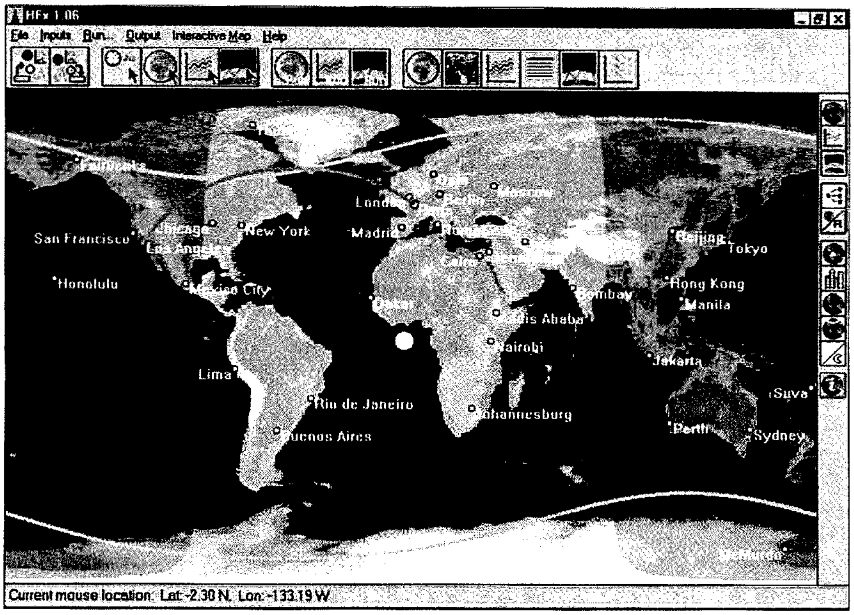

Fig. 6. Main screen, showing transmitting and receiving station placement, solar position, major world cities, great circle path between Tx and Rx, auroral boundaries based on geomagnetic activity and day/night terminator. These items may be turned on or off at user's discretion.

Conclusions

The results of my unofficial field testing were quite amazing. HFx was able to predict that communication should have been possible for recorded DX spots the vast majority of the time. In many cases, HFx showed a small window of opportunity at the Maximum Usable Frequency and, sure enough, spots would start showing up on the cluster. I also checked HFx against my station log randomly over a period of about six months and the vast majority of contacts fell within the plotted window of opportunity. I found the hop mode to be quite educational in that it gave a graphic representation of the signal path, availability and signal-to-noise ratio.

"I do like technology and, like most hams, I love toys; HFx fits both requirements."

I enjoyed using HFx. I don't have a "big gun" station and probably never will, but I do like technology and, like most hams, I love toys. HFx fits both requirements. I would like to see the next release of the software include a display of Lowest Possible Frequency and possibly dynamic real-time entry of the time at the transmit location, but for now I think the folks at Pacific Sierra Research Corporation have a winner.

Although it would take a serious amount of research with both transmit and receive stations available at different times, places, times of the year, and solar conditions to thoroughly test out any propagation software, I found the results that HFx produced for both my contesting experiment and setting up skeds to be quite impressive. One should understand that any propagation program just collates past statistical data in the hope of applying it to the future, which is never entirely predictable. Using propagation software does, however, give one a place to start when turning on the rig and wondering where that DX might be lurking or when the best time is to call that friend on the other side of the country. The little bit of magic that a program like HFx can perform sure can't hurt, and, after all, doesn't amateur radio involve just a little bit of magic?

Availability

HFx is priced at $129. If you are on the Internet you can get product information, order HFx or download a demo copy of HFx at: <http://www.psrv.com/hfx/>. Or, contact the company directly: Pacific Sierra Research Corporation, 2901 28th St., Santa Monica CA 90405-2938; (800) 820-4PSR, (310) 314-2300 outside US and Canada.

73 Review

MultiFAX® AM/FM WEFAX Demodulator

Fine-tuning a satellite tracking system.

Larry R. Antonuk WB9RRT
P.O. Box 452
Marlborough NH 03455

I had spent the last several weekends working on my overall weather satellite Automatic Picture Transmission (APT) receiving system. My Hamtronics R139 was built and working well. The Woodhouse Communications Turnstile antenna was assembled and mounted on a tripod on the roof, along with my LNG-137 preamp. I was receiving weather satellite transmissions left and right. Unfortunately, most of the passes I received were coming in totally randomly. I was simply recording everything that came in, and laboriously sorting through the pile later. This worked, but it took several minutes to watch each image paint itself on the screen—only to find out, in some cases, that it was a totally uninteresting shot of some clouds out over the ocean. Since I was primarily interested in the weather occurring in my own general vicinity I found that I was wasting an awful lot of time. It was time to do some homework on my new demodulator.

I purchased my demodulator based on recommendations from a couple of knowledgeable friends, rather than on my own understanding. Once I had my weather receiver up and running well enough to hear anything, I fired up the demodulator and learned enough about it to demodulate pictures. Then I went back to improving my antenna installation. Now that the antenna was installed I had time to fine-tune the final part of the system.

My demodulator was the external demodulator unit from MultiFAX®. This demodulator works in conjunction with MultiFAX's MFMAP Version 7 software, providing a means to decode several types of weather satellite images. I was new to the satellite image business, and wasn't sure exactly what I might be wanting to decode—either right now, or in a year or two. The MultiFAX unit supported NOAA, Meteor, GOES, Meteorsat and HF WEFAX. I had also chosen the MultiFAX because it comes in an external version—I didn't have to tear my PC apart to install a card, and I could easily use the external unit with my laptop. (Of course, the MultiFAX does come in a PC card model for the diehards.) The MultiFAX hooked up via the PC's printer port for full parallel data operation. I knew that some units only used the serial port, which limited their overall data throughput. (I had certainly learned this with my experiences with the home-brew, shareware-supported demodulators.) Another necessity was the ability to record satellites unattended—I certainly couldn't be home to fire the software up in the middle of the day.

What little knowledge I accumulated had easily taken me to the point where I could decode and display images. The installation of the unit itself and the MFMAP7 software was a cinch—just plug the box into your computer with the supplied cable, copy the files from the disk, and hit the road. MFMAP7 takes up about 800 kilobytes on your hard drive, but you'll need about 4 MB total available space. A complete satellite pass gets "recorded" to the hard drive in real time, and takes as much as 3.5 M per image! About the time I decided I needed to learn more about the MultiFAX unit I also found out I needed to do something about the couple of dozen 3.5 MB files on my hard disk—things were getting pretty crowded!

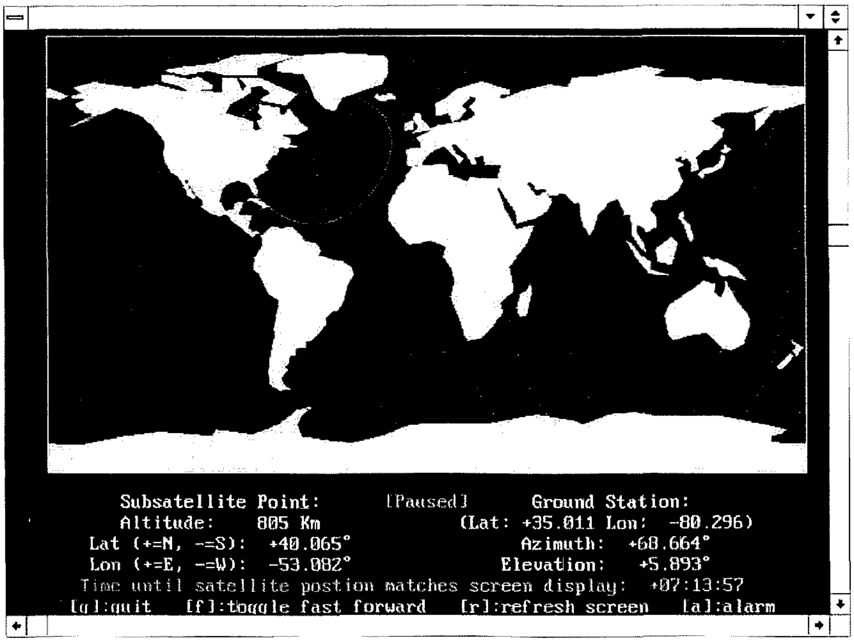

Photo A. MFMAP7 provides a real-time graphical display as it plots satellite locations.

Using it? Simple!

At this point I decided to read the manual, which, in retrospect, was not a

bad move and perhaps should have been attempted earlier on in the game. To begin with, I found that there was no reason to save all of those fat files on my hard drive. The MultiFAX software uses three main types of files. The first type is a Picture file. This file is a complete data recording of the entire satellite pass, and is the 3.5 MB file discussed earlier. This file is recorded from the pass, or the tape recording of the pass, and stored to disk. Once stored, the image is called up using the Display menu of the program. The display menu lets you zoom in and out, invert the image, change the brightness and contrast, and perform various types of image enhancement. Once the image is modified to provide the best picture, you can save it as a View file. A View file is saved in binary format, and consists only of the interesting information cropped from a Picture file. This lets you save just the valuable information from each image, and not use up disk space with useless images. The third file format is the common .GIF format. Either the View or Picture screen lets you output the image to a .GIF file that can be easily used in desktop publishing programs or printed out.

Once I determined that there was no need to be hoarding those huge Picture files, the process became much simpler. To record a file, you simply select the Record option from the Main Menu. This lets you give a filename to the image you are about to record. At this point MFMAP7 displays a graphic signal level meter. This would more accurately be called an on-screen oscilloscope. The meter is a display that shows the relative "brightness" level of the received signal for its entire trace across the screen. A too dark signal will be seen as compressed near the bottom of the display, while an overly white image will be seen crowded near the top of the display. It's a simple matter to adjust the output control of the MultiFAX unit to correct the image, providing a proper range of contrast for the image—before you even start recording. Once the contrast is adjusted you simply hit any key, and the MultiFAX goes into AutoStart mode. This mode synchronizes on the left edge of the image, so the recording will start at the proper time to create the image properly aligned with the screen. (Of course, if for some reason the signal is lost and the image starts recording with the edge going down the middle of screen, the situation is easily corrected once in the Display menu.) As the unit records, the image is traced out to the screen a line at a time, over the next several minutes. A keystroke stops the recording, saving as much of the image as has been recorded up to that point.

The recorded image is then called back up in the Display menu. This menu allows zooming in and out, inversion of the image, changing of the brightness and contrast, false colorization, and a variety of other functions. A section of a Picture is saved as a View, which takes up only a few hundred kilobytes of disk space.

Scheduling the recording

After the novelty of satellite imaging wears off, you'll find yourself not necessarily wanting to record every single bird that passes within earshot. You'll probably want to tailor your recordings to capture just passes that go right over your location, or perhaps you want to capture all the images you can—but just in the three hours before Saturday's ball game. In this case, the Record menu offers a timed function that will start recording a single image at a specific time, based on your computer's clock. In addition to this "wait until recording" mode, MFMAP7 also includes a utility that allows use of a separate schedule file, and will call the Record module at specific times. Using the feature you can record up to 200 passes automatically—as long as you have about 700 MB of space available on your hard drive!

But how do you know when the satellites will be coming over so you can set the timer properly? Luckily, MFMAP7 has a built-in satellite tracking function. This uses a graphical display that shows a world map, and traces the path and footprint of each of the satellites. This display works in both real and accelerated time, so it is very easy to see what will be visible from your location for the rest of the day. The software even tells you the number of hours to wait until the next pass of the selected satellite. Of course, as with all tracking programs, you'll need to download the Keplerian elements on a regular basis so the program can fine-tune itself. These are available from the MultiFAX BBS or via the Internet. The satellite tracking feature of MFMAP7 supports the Kansas City Tracker system, meaning you can have the software automatically adjust your antennas for you as the satellite passes over.

Once you have the proper images recorded, the MultiFAX software supports grid and map functions that allow the user to overlay latitude and longitude lines, as well as map information. More advanced "frosting on the cake" features include the ability to create pseudo three-dimensional images, colorization based on temperatures, infra-red optimization to allow temperature data to be read directly from an image, and even animation. (Yes, you can produce your own moving cloud images just like on the six-o'clock news!)

The MultiFAX WEFAX Demodulator, combined with the Hamtronics R139 receiver, and the Woodhouse Turnstile antenna, has proved to be a very satisfactory weather monitoring station. However, even with all the resources available, including one's own "eye-in-the-sky," I still find myself occasionally getting outsmarted by the weather. I suppose this is simply Nature proving that she's superior to technology, and may never change. Until it does, I still keep an umbrella in the trunk. For more details contact: MultiFAX®, 321 Mason Road, Fairport NY 14450; Telephone (716) 425-8759; FAX (716) 223-6198; BBS (716) 425-8759.

An Enhanced Automatic Voltage Controller

Make this project even more useful.

Sam Ulbing N4UAU
5200 NW 43rd St.
Suite 102-177
Gainesville FL 32606
E-mail: n4uau@afn.org

I try to read all the projects published in the amateur radio literature, especially those in *73* and *QST*. There are many neat ideas in these articles and sometimes if I find a project I can use in my shack, I'll build it. Even if I don't build the project, it is fun to see the different solutions people offer to solve a problem. I have learned a lot about electronics just trying to understand how the different designs work, and I like to design projects myself, so I am always looking at a project to see if I can think of a different (and possibly better) way.

I recently read "Automatic Voltage Controller" (*73*, August 1996). It seemed like a great project and was one I wanted to build. I have had firsthand experience with voltage

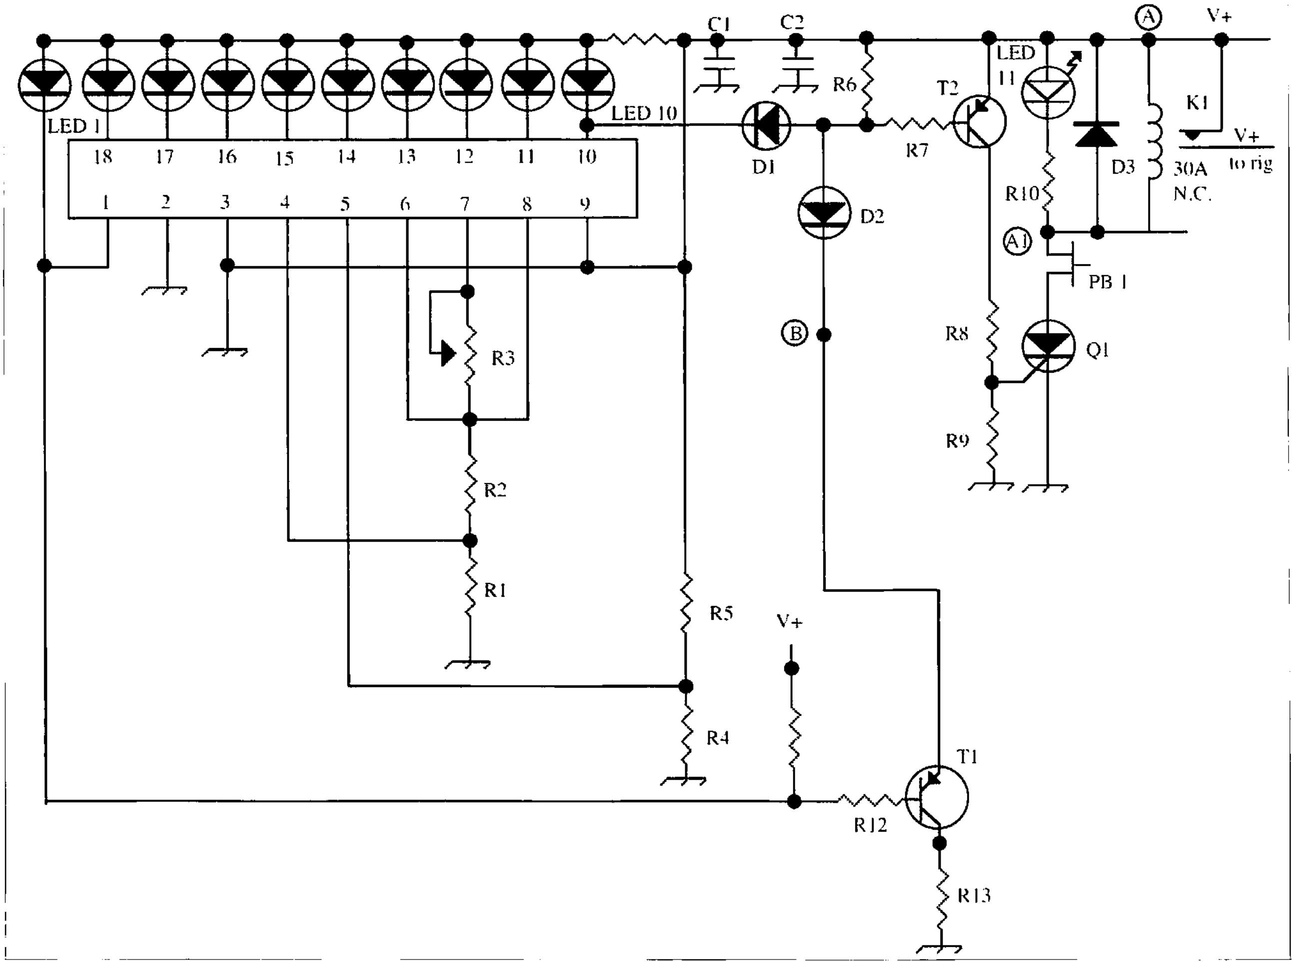

Fig. 1. Schematic for the modified Tiny Tic-Tac Tester (left) with the enhanced voltage controller (right).

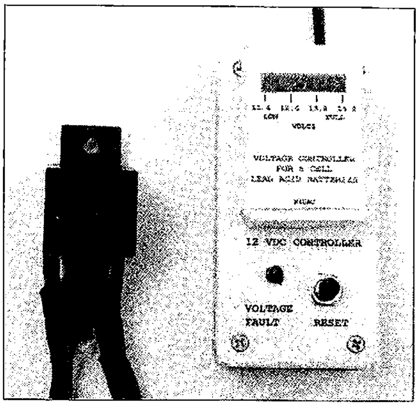

Photo A. Enhanced Automatic Voltage Controller with remaining 40 amp relay.

out-of-range problems. I use an IC-735 on my sailboat when I cruise, and like all sailors, I never seem to keep my batteries fully charged. One day when transmitting, the rig just shut itself down. Eventually I got it restarted but it was not the same. Evidently the low voltage had ruined one of the ICs in it. That turned out to be a $100 learning experience. Is it any wonder I was interested in this project?

Enhancements to the AVC

After thinking about the project for a few days, I decided I wanted to enhance it. The project shown uses zener diodes to set the upper and lower voltage control levels, which works fine but doesn't let you see what the actual voltage is during operation. You may recall I wrote a project article for *73* in March 1996 ("The Tiny Tic-Tac Tester") that was based on an LM3914, which accurately displays voltages. I wanted to add this feature and use it to control the relays as well.

Another feature I thought might be useful was latching relays. Low voltage often occurs when you are transmitting. When you stop transmitting, the load decreases and the voltage increases. With the original design, the AVC would turn on again; indeed, it seems possible that the relays would chatter on and off. I wanted to have those relays trip and stay tripped until I was able to correct the problem.

Finally, I wanted to eliminate as many of those mechanical relays as possible and use electronic relays. My enhancement eliminates two of the three relays.

The design

Fig. 1 shows my enhanced controller schematic. I have drawn it in two parts. The left-hand side is the same circuit used in "The Tiny Tic-Tac Tester," with R1, R2 and R3 set for a voltage range of 11.4 to 15.0 volts. A

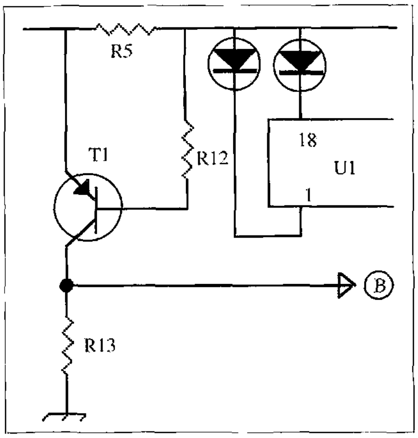

Fig. 2. Modification for dot mode display. Connect T1 as shown. Note: R11 is not used.

complete description of this circuit is given in the original article. Briefly, the supply voltage is divided down by R4 and R5 and fed to pin 5 of the LM3914. R1, R2 and R3 are used with the onboard voltage reference to set the low voltage limit at pin 4 and high voltage limit at pin 6. I tied pin 9 to V+ to get a bar mode display for this project. When the supply voltage is less than 11.4 volts, all LEDs are off. As the voltage rises from 11.4 to 15 volts LEDs turn on from left to right. The higher the voltage the more LEDs are on until at 15 volts all the LEDs are on. With 1% resistors for R1 and R2, this is an accurate expanded scale voltmeter. I set R3 for an LED current of about 4 mA to limit the power that LM3914 would have to dissipate. It would, of course, be possible to use the dot mode instead of the bar mode, requiring only a small design change for the low voltage input (see "Alternative Circuits" below).

While an LED voltmeter may seem obsolete when fancy digital voltmeters are readily available on the surplus market, the LM3914 offers a feature no digital meter can. It can be an active part of the circuit, allowing it to control the circuit, as well as displaying the voltage in a passive fashion. To see how this works, note that I have attached a wire from the cathode of LED #10 (the one that turns on when the voltage reaches 15.0 volts) to the base of transistor T2. When the supply voltage reaches 15.0 volts, the LM3914 turns on LED #10 by allowing current to flow from its cathode to ground. When it is off, the LM3914 does not let current flow. Because T2 is connected to the cathode of LED #10, current will also flow from its base to ground so T2 turns on when the LED turns on. So with just one additional wire the LM3914 can turn on a control transistor when the voltage reaches 15.0 volts.

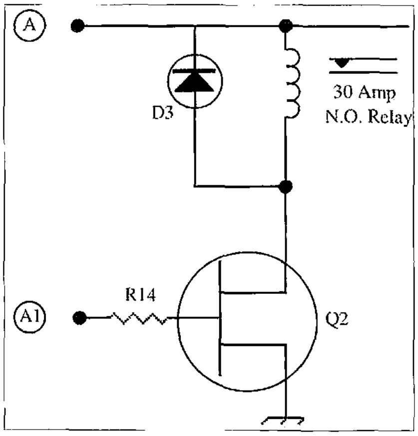

*Fig.3. Modification to use NO relay. Replace NC relay between points **A** and **A1** in **Fig. 1**, with circuit shown.*

The other control point is when the voltage falls below 11.4 volts and LED #1 turns off. This is done the same way except that I wanted to turn on T2 when LED #1 turns OFF rather than when it turns ON. T1 is used to invert the effect of LED #1. When LED #1 is on, current is flowing from its cathode to ground, and because T1 is connected to its cathode, T1 is also turned on. This puts V+ across R13, and therefore on the base of T2, preventing current flow from the base of T2. When LED #1 shuts off, T1 shuts off and the voltage across R13 goes to zero, which lets current flow from the base of T2 to ground, turning it on.

The diodes D1 and D2 prevent interaction between LED #1 and LED #10 and make control of T2 an "OR" operation. If LED #1 is off *or* if LED #10 is on, T2 turns on.

With the LM3914 voltmeter now turning on T2 at the limits I set, I needed T2 to trip a latching relay. Q1 is that relay. Q1 is an silicon-controlled rectifier (SCR). One characteristic of an SCR is that when it is turned on (conducting) it will continue to conduct until the current through it stops. In other words, it is latched on. The gate of Q1 is used to turn the SCR on. When T2 is off, no current flows through R9 so Q1's gate is at ground and Q1 does not conduct. When T2 turns on, the gate is pulled high and current flows through Q1, energizing relay K1 and opening it. The only way to close the relay is to stop the current through Q1. Push-button PB1 does this reset job. LED #11 indicates that the circuit has tripped.

That's all there is to it! The circuit draws about 25 mA when it is in standby (depending on how many LEDs are on) and 200 mA when it trips the relay. Not much power—and *that* can be reduced by using the dot mode display if you desire. See below.

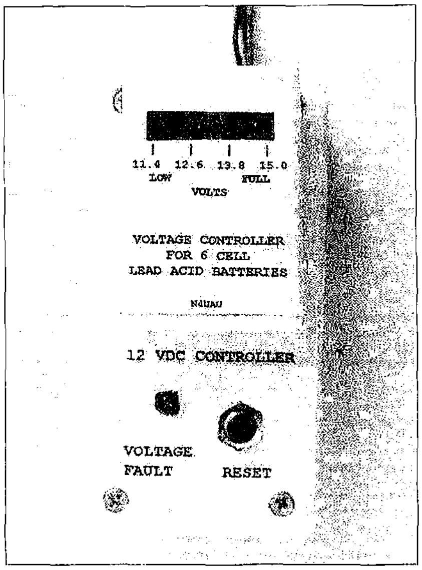

***Photo B.** Enhanced Automatic Voltage Controller in its "elegant" case.*

Alternative circuits: Using the dot mode for voltage display

While the circuit does not draw much power, it is possible to reduce the current to around 12 mA by operating the LM3914 in the dot mode. This will also reduce the power dissipated in the LM3914. If you wish to run the LM3914 in the dot mode, LED #1 will not work as a control point because it has too high a leakage current in the dot mode (this is a basic LM3914 design fact). The circuit is easily modified, as shown in **Fig. 2**. R15 will cause T1 to be on whenever *any* LED is on. When the voltage falls below 11.4 volts all the LEDs turn off and no current flows through R15 (except leakage current). Setting R3 at about 360 ohms (for 4.0 mA of LED current) gives a voltage drop of about 1.4 volt across R14 when any LED is on which turns on T1.

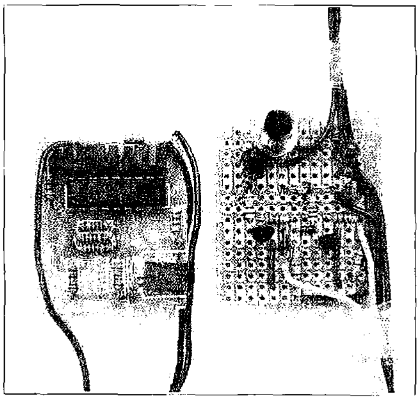

***Photo C.** "Guts" of the Enhanced Automatic Voltage Controller. Note the simple parts layout on the Radio Shack PC board.*

Using a normally open relay

If you want to build this project but don't want to have to locate a high-current NC relay, you might do what I first did, and use the Radio Shack™ NO relay (275-226). To use the NO relay it is necessary to modify the circuit a bit. See **Fig. 3**. Q2 is a MOSFET which is turned on when Q1 is not conducting because its gate is high. This holds the relay closed. When Q1 conducts, Q2 shuts off and the relay opens. You might wonder why Q2 is a MOSFET and not an NPN transistor. Q1 is basically a diode so when it conducts the drop across it is about 0.7 volts. This will not turn off a transistor but will turn off a MOSFET which needs about 2 volts on its gate to conduct. This circuit will draw around 200 mA because the relay coil is energized all the time. The addition of a simple SPST switch between the coil of K1 and V+ will let you de-energize the coil when you are not using the rig. You still get the voltage display from the LM3914 and current draw is only 25 mA.

Parts List	
(All resistors 1.4 watt 5%, unless otherwise noted.)	
R1	7.68k 1%
R2	3.83k 1%
R3	3.2k (1.2k fixed and 2.0k pot)
R4	10.0k 1%
R5	5.0k 1%
R6	24k
R7	15k
R8	100k
R9	15k
R10	1k
R11	24k
R12	15k
R13	10k
R14	33k
R15	360 ohms
C1,C2	1.0 µF
T1	PN2907
T2	PN2907
Q1	2N5061
Q2	IRFD020
D1,D2	1N4148
D3	1N4001
LED#1-11	LEDs
PB1	NC push-button

Obtaining the parts and building the project

I built the AVC part of the circuit in a small Radio Shack box and glued my modified TT-T Tester (still in its original Tic-Tac-box case) to it. It may not look elegant but it was quick and easy to build and it works fine. After all, I wanted to improve the circuit, not the package!

Parts are available at the usual parts suppliers. I still have parts (including a PC board and 1% resistors, for the 11.4 to 15 volt range) and can supply the parts for the rest of the project, except for a PC board. As **Photo C** shows, the rest of the circuit is simple enough that it can be easily made on a Radio Shack universal board (#276-150).

Tiny Tic Tac Tester: All parts, PC board, instructions—$15.

Voltage Values Displayed by LM3914	
LED# Turns On	When Voltage Reaches
LED#1	11.4 volts
LED#2	11.8
LED#3	12.2
LED#4	12.6
LED#5	13.0
LED#6	13.4
LED#7	13.8
LED#8	14.2
LED#9	14.6
LED#10	15.0

All parts for the Enhanced Voltage Controller (includes the Tic Tac Tester parts, plus all parts and instructions for the controller except a PC board; includes a 40 amp NC relay—$25. 73

Still More Stress

For the last few months, we've been discussing electrical, mechanical and thermal stress, examining how each affects various components. Let's continue:

More caps

When we left off, we were looking at capacitors. The problem with caps is that there are so many different kinds, it makes it hard to generalize about them! So, let's look at still a few more types of caps.

Plastic capacitors, typically made of polypropylene or polystyrene, are used where low drift and accurate capacitance are required. Many plastic caps come in small, green, dipped packages and are somewhat rectangular, often with rounded corners. Inside the hard-dipped shell is a foil and plastic arrangement that's wound in layers, at least in the larger values. The stability of plastic caps comes from the inherent stability of the plastic itself, which changes its dimensions and density very little with temperature.

Plastic caps are very rugged. You won't break them if you drop the rig. (Of course, if you sit on it, that's another story.) Their voltage ratings vary from around 50 volts to considerably higher voltages. As with any cap, you can blow holes in the insulating layer with too much voltage.

No plastic cap should get hot in normal operation. I've never seen a leaky one but, of course, it could happen. As with any leaky cap, the resulting current flow would heat up the part.

External heat doesn't seem to be much of a problem with these caps, either. The plastic insulating layer inside could melt if things got *really* blistering, but that would be an extreme circumstance. I have seen a couple of open plastic caps near big heat sinks, but not for many years. I suspect their reliability has increased over the last 10 or 15 years.

Variable caps

Most variable caps use either air or plastic for their insulating layers. Air caps are nothing more than plates with space between them! They are fairly rugged, but the plates can be bent pretty easily, making them subject to mechanical stress. If the plates get too close to each other, the cap will be more susceptible to overvoltage arcing. And, of course, if the plates actually touch those from the opposite side of the circuit, the cap will become a conductor, and cease being a capacitor at all!

Plastic variables are less prone to plate bending because the plates are pushed up against the plastic, rather than hanging free in space. They are pretty hard to break, unless you turn one so hard you tear the plastic. It's not easy to do.

While receiver circuits use such low voltages that they don't stress variable caps, the voltage ratings of the parts must be carefully observed when the caps are used in transmitters. A high SWR, or a transmitter pushed to produce more power than it was built for, can raise the RF voltage high enough to punch through plastic caps, or to arc over air caps. Plastic caps will be ruined if the plastic has holes zapped through it, but air caps may survive. An arced air cap, though, will have burn marks on it, and those areas will not work as well as the normal metal, resulting in a less-efficient cap. Also, a hot enough arc may actually melt the metal plates, destroying the capacitor. I've seen plenty of arced air variables in antenna tuners, though, and that still seemed to work fine.

Important note: The voltage ratings for caps are normally stated in volts DC. At radio frequencies, the number must be derated (made smaller) by a factor that depends on the frequency of operation—so don't assume a 100-volt capacitor will withstand 100 volts of RF at 146 MHz! At such a high frequency, the part may break down with perhaps only 30 volts across it. Cap manufacturers usually offer derating charts that show permissible voltages at various frequencies.

> **"If things get hot enough to melt metal plates you have more to worry about than capacitors!"**

Like all caps, variables shouldn't get hot. Plastic ones can be leaky, but it's rare, especially since they pretty much never have serious power applied to them. Air variables only leak if they become very grimy or oily, opening a new path from one side to the other. Of course, if you arc an air variable, it isn't going to stay cool!

External heating can kill a plastic variable, but generally not an air variable. If things get hot enough to melt metal plates, you have more to worry about than capacitors!

Inductors

Coils and transformers are subject to stress, too. Many are tightly wound and have shellac or something like it coated on the wire for insulation, rather than the plastic jacket used on normal hookup wire. It's often important for the insulation to be thin because the tight windings provide maximum magnetic energy transfer, thus maximum efficiency—but that thin insulation can break down from excess voltage.

Essentially, the adjacent windings act like capacitors because the two wires can, at any given moment, be at different voltages as the energy moves back and forth within the coil. Two conductors at different voltages, separated by an insulator (here, the wires' insulation) equal a capacitor, right? So, the rules for caps apply here, as well as others relating to wire itself (like melting!).

Typically, coils and transformers break down in two ways. Adjacent windings short to each other, especially in high-voltage transformers, such as the "fly back" transformers in TV sets and computer monitors. Or, windings melt, causing an open circuit. That, of course, is caused by excessive current heating the wire enough to melt it. It happens more often than you might imagine. In fact, it's probably the primary cause of transformer failure.

Although external heating is unlikely to kill inductors, internal heating is their nemesis. Like resistors, though, most inductor failures are caused by some other circuit's pulling too much current through the wire. And, oddly, the damage may be on the other side of the magnetic circuit! Many power transformer primaries open after something shorts out the output of the secondaries! The secondaries themselves are often unharmed.

Switches and relays

Contacts have several failure modes. Overvoltage can cause them to arc, just as in the plates of an air variable capacitor, which is essentially what a switch is when it's off. As you turn it on, the contacts get closer and closer together, until the voltage can break through the air between them and arc over.

Overcurrent can actually weld contacts together! I used to have a linear amplifier whose power switch did that all the time. The inrush current to the power transformer was so huge that, if the switch contacts happened to touch right around the moment the AC power input's wave was at maximum, the switch would weld itself in the "on" position, requiring me to pull the switch out and break the contacts apart with a screwdriver (after unplugging the amp, of course)! It used to happen only about once in 20 times, but it was a pain in the neck.

Relay contacts are just switch contacts, so they suffer the same problems. Contacts should never get hot. If they do, check them for blackening or loss of plating. As long as the resistance is nice and low, significant heat is not going to happen.

Many people file contacts, but it is a cure somewhat worse than the disease. It will work for a little while, but the loss of the plating which occurs with filing usually leaves pure copper, and copper makes soft, easily damaged switch contacts—that's why they plate the darned things in the first place. Filed contacts usually go bad again in very short order.

Connectors

There are so many kinds that it's hard to classify them. Normally, connectors are hardy, unless you arc them over with way too much voltage. Some insulating materials used in RF connectors, though, can heat up if lots of power is applied, especially at very high frequencies. After all, a connector is a capacitor, too, what with its having two conductors separated by an insulator. It really pays to observe power and frequency limits for the various kinds of connectors, and to always use connectors appropriate for the purpose.

Well, I think we've covered the stress issue pretty well. Next time, something different! Until then, 73 from KB1UM.

The Keys To Success

As a follow-up to previous columns which described various telegraph keys that my ham radio classes have had fun making, I'll describe one that many students used for this year's Science Fair at our school. Most of the materials are easy to obtain so we didn't run into that as a problem.

"All the kids had a chance to participate in contributing something to the display."

Construction

For this key you will need: 10 feet of insulated wire (commonly called bell wire), a dry cell, a three-inch by four-inch piece of aluminum foil, three brass paper fasteners, a large nail, a paper clip, and a milk carton.

First, cut away the top of the carton. Then cut a piece one inch wide by three inches long from the center of one side of the carton. Next, cut the opposite side.

Cut a six-inch piece of wire (to be used later). Then wrap the remainder of the wire around the nail to make an electromagnet. Leave six-inch ends to the wire. Remove the last inch of insulation from each end, and also from the ends of the six-inch piece. Wrap the aluminum foil around the strip you cut from the side of the carton. Then fasten it at the top of the milk carton, using a brass paper fastener. At the same time attach one end of the wire from the electromagnet to the fastener. At this time also attach the short piece of wire to its fastener.

Now slip the dry cell inside the milk carton. Attach the other end of the short wire to one pole of the dry cell, and the wire from the electromagnet to the other pole.

Attach the paper clip and a brass fastener to the cut strips at the side. Stick a small piece of cellophane tape over the paper clip. Put the electromagnet in place with the end about one-quarter inch above the paper clip.

Displaying the keys

Now the kids in your class will be ready to put all the telegraph keys on display or to put their own telegraph company into business. Sometimes there's a problem getting the milk-carton telegraph key to click. If you don't get a click, move the electromagnet down a tiny bit at a time until you do.

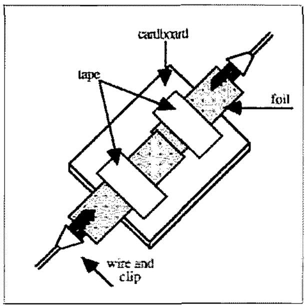

Fig. 1. The milk-carton telegraph key.

For this display of telegraph keys that one of my classes was working on, the kids came up with a great idea. They not only showed all the different types of homemade telegraph keys that were fun to make, but they did some research, built older models, and included photographs of some classics.

In a future column I'll show photos of the actual displays the children organized. It was a wonderful project and it gave all the kids a chance to participate in contributing something to the display.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

As has been my custom these past 20 years of "RTTY Loop," let me be among the first to wish each and every one of you a Happy New Year! May this year be one of health, success, and peace for us all.

We have been discussing, of late, all of the latest computer programs available for radio teletype, packet, and other digital forms of communication. One question often asked is where these programs may be found. This month, here's a look at two massive online sources.

CompuServe

The granddaddy of online services, CompuServe, has recently revamped its interface and, with CompuServe 3.0.1 as an access program, the service has a new face, if not new content. The amateur radio segment of CompuServe can be reached by the GO HAMNET command. **Fig. 1** shows the opening screen of this venerable resource.

Fig. 2 shows the variety of topics covered in the message section, ranging from scanners to packet to company-specific information. Within each section are a few to dozens of messages dealing with a wide range of information. This is a good place to post that question or puzzle that interests you. It is likely the answer will be there the next time you check in.

A similar range of topics is covered by the file libraries, shown in **Fig. 3**. With 23 sections of information and hundreds of files available, this is often the first place to find the latest release or update of ham radio software.

Over the years, I have always found a wide variety of material on the CompuServe system, with a breadth that is hard to beat. You don't need the latest access program to use the service—the content is the same no matter which door you come in.

> ***"Recently-introduced economy and flat rate pricing structures have made using CIS and AOL much more attractive."***

America Online

Although quite a bit younger, America Online has made quite a name for itself, and has quite a nice amateur radio section, as well. **Fig. 4** shows the entrance screen for their Ham Radio Club, reached with the keyword Ham Radio. There are quite a few features, as can be seen, although the ARRL section is a tad dated, with information many months old online.

Just as with CompuServe, a message section is available, as shown in **Fig. 5**, with a variety of topics and room for thousands of messages. Unlike CompuServe, where messages scroll off the system after a while, AOL seems to hold them online for much longer, making searches of topics and threads a bit easier.

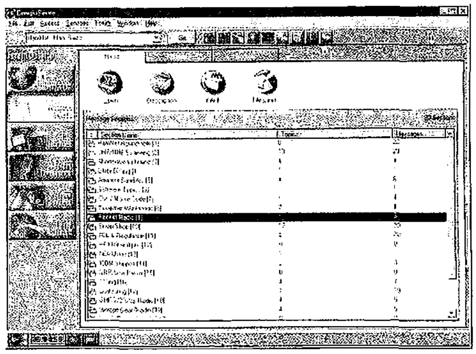

Fig. 2.

Their *Software Exchange*, shown in **Fig. 6**, supports file libraries for a variety of systems. Even the Macintosh, which seems poorly represented on some systems, has a section; **Fig. 7** shows what is currently available. There is also a live conference area, which sponsors online chats, giant cyberworld QSOs, on various ham radio topics.

Although these online services were once quite expensive, recently introduced economy and flat rate pricing structures have made using CIS and AOL much more attractive. If you are on one of these services, why not take a look at the ham radio boards, if you have not already. For some users, these represent an attractive alternate to other types of online providers.

An example

While online, I received a message on CompuServe from S. Neil Xenias N4CTB, who posed the following question: "I have recently purchased a Dovetron Terminal Unit, and I'm wondering if it is worth adding to the digital portion of my ham station. It appears to be operational, and I noticed the digital (RS-232) output port on the rear panel, thinking perhaps it might work with a computer-based station. I have contacted Dovetron for advice, and was hung up on (twice) when I mentioned requesting technical assistance. So with hurt feelings, I thought of asking you for advice. Should I keep this thing or cannibalize it?? Thanks in advance, Doctor, and my best 73!!"

Well, Neil, the Dovetron terminal units have been quite popular for many years, and I would be surprised if it would not do you well. I understand the need for documentation, though, even if the folks at Dovetron do not. So, I turn to the readership of this column. Anybody? If so, drop me a note, or direct the information to Neil directly. I know you won't let me down.

Of course, when it comes to online sources, you can't go wrong surfing on over via the Internet to the RTTY Loop Home Page. I have been doing some upgrades and am trying to put some of the programs you have

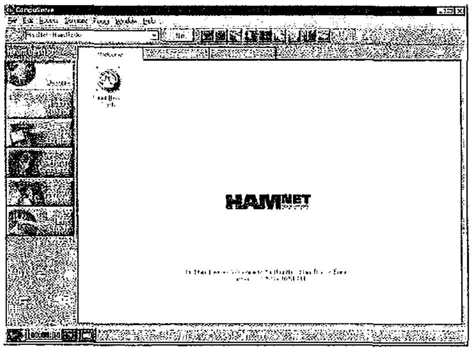

Fig. 1.

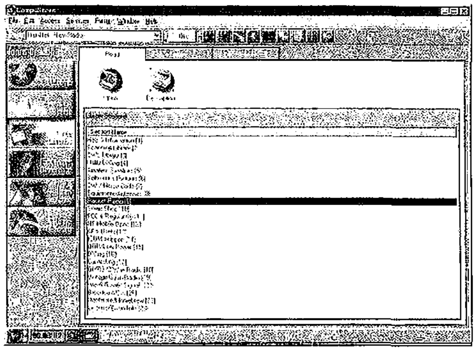

Fig. 3.

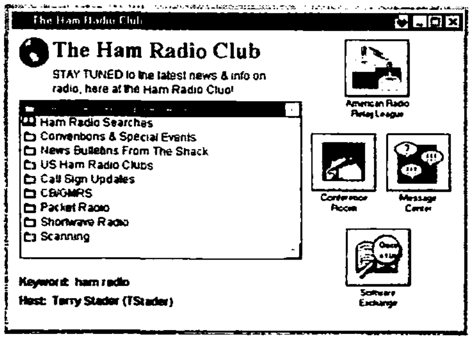

Fig. 4.

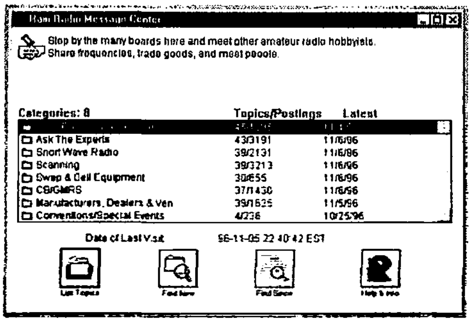

Fig. 5.

asked about up for downloading, as well as links to many ham radio sites on the World Wide Web, and there are many, many ham sites! Stop by the page at http://www 2.ari.net/ajr/rtty/ and see if you can't find something interesting. If you have, or know of, an amateur radio related site, drop me a line and let me know, so that we can establish a crosslink. Speaking of links and webs, I plan some antenna work this fall and winter, when the trees are bereft of their foliage. Stay tuned—those of you who remember my exploits with a bow and arrow a few years back won't want to miss this one!

So, let me hear from you, via mail, or via E-mail at ajr @ari.net, or Marc WA3AJR on AOL, or 75036,2501 on Compu- Serve. You are all part of this column, and I do love hearing from each of you. ■

CARR'S CORNER

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041

Some Potpourri: Wanna Make History?

Wanna help make history and do some VHF hamming in the bargain? Or how about honoring history, making some history and doing some neat hamming? All are possible, although it's going to be pretty hard. The Irish Radio Transmitters Society (IRTS) announced a contest last year for the first transatlantic ham communication on 2 meters.

The winners will each receive one of two crystal glass trophies generously provided by the Waterford Crystal Company, whose products are known worldwide. In fact, if you've bought any of that stuff you'll know that a custom piece of Waterford is a fine and expensive prize indeed! Waterford Crystal, after all, is one of the finest producers of crystal glassware in the world (and an Irish icon).

"The winners will each receive one of two crystal glass trophies generously provided by the Waterford Crystal Company."

The crystal trophies are called the Brendan Trophies, after the legendary Irish folk hero, Saint Brendan. Among the Irish, he is probably second only to Saint Patrick, and is often referred to as "Brendan the Bold." And why was Saint Brendan so bold? Well, if his travels, chronicled in *Navigatio Brendani* (*The Voyages of Brendan*), are actually history instead of folk tales and storytelling, then he may well have sailed to the east coast of North America—transatlantic—in the end of the fifth, or beginning of the sixth, century A.D. ... in a leather boat! There is about as much time between Brendan and Leif Ericson, who also apparently made the journey, as there is between the first English settlements in North America and Wayne Green's birthday. In other words, ol' Brendan was a pretty early traveler to North America, if the stories are true.

Internal evidence of the legend suggests that he probably reached Iceland or Greenland, and possibly Nova Scotia, nearly half a millennium before Leif Ericson. The stories date to that time, and have verifiable facts, or at least suggestions of facts. That Brendan's feat is at least possible was proved in 1976 by Tim Severin, who repeated the journey in a leather boat of traditional design. If you are one to bend an elbow in honor of the bold (or the foolish), then St. Brendan's feast day is May 16th each year.

For radio signals, the North Atlantic path has always been something of a challenge because it crosses magnetic lines of force at high latitudes, and is bombarded with assorted troubles such as the aurora, particles and radiation from space. Indeed, "something of a challenge" often means downright difficult.

The short-term radio propagation condition predictions are usually made for the North Atlantic path because it describes nearly-worst-case conditions. An ionosonde device tests the path between the continents, and that data is published on radio stations such as WWV.

Marconi was the first to cross the Atlantic on a radio "boat" ... about a millennium and a half after Brendan and a millennium after Leif (by the way, I know a Norwegian lady who celebrates October 12th not as Columbus Day, but as Leif Ericson Day). Marconi probably used LF frequencies, which were more practical than the shortwaves in those days, to transmit the Morse code letter "S" from the west coast of England to a receiving site near St. Johns, Newfoundland, in December 1903.

It took another 20 years for the shortwave radio to cross the Atlantic. On the night of 27 November, 1923, the contact was established by ham radio operators ... and it startled the world! Today, anyone with a few watts loaded into a wet string antenna can work transatlantic contacts with ease. I recall one old fellow who gave ham club speeches on early radio, having been one of the first post-war, i.e. post-World War I, hams to be licensed. In about 1960, he came to the Potomac Valley Radio Club, of which I was a member, and gave us a talk. (Personal note: Former ARRL President Vic Clark W4KFC picked me up for meetings; because I am an epileptic I could not medically qualify for a driver's license until I was 23.) He told us how they were using frequencies as close to 200 meters wavelength (around 1,500 kHz in the AM BCB to our present-day 160 meter ham band) as possible. The HF frequencies were considered useless (which is what prompted the famous "... 200 meters and down" statement that is enshrined in Clinton B. DeSoto's book of the same title). The antenna was strung out across his father's Piedmont Virginia farm, and was one of those three-wire flat-tops that ran about 600 to 1,000 feet down the meadow. "DX" was any station two states away.

In 1924, he went away to the University of Virginia to study engineering, and left the ham station to his younger brother. When he returned for Thanksgiving, he noted that the flat-top antenna was gone, and was replaced with a couple of puny little things between 60 and 120 feet long. His brother sheepishly told him "we are using the shortwaves now." Skeptical, the fellow decided to send a message to his roommate, who lived in Ohio. So, hearing a station with an "8xx" callsign (they didn't use national designators in those days, so one-by-two callsigns such as "1AW"—Hiram Percy Maxim's callsign before it became "W1AW"—were used) he asked the guy to relay the message to Canton, OH. "Sure, OM, I'll be glad to, but you are probably in a better position to relay it yourself than me because I am FRENCH 8xx." He darn near fell off his chair! His first DX was over the supposedly intractable Atlantic Ocean, with little more than 15 watts of power.

Now, back to the Brendan Award. Some people claim that the 2 meter Transatlantic Challenge sponsored by IRTS will be a greater technical achievement than Marconi's 1903 work ... so here's your chance for immortality. The award will go to the first two amateur radio stations who establish two-way contact on 2 meters, across the Atlantic ocean, without using a satellite or earth-moon-earth (EME) methods. That would be cheating!

Both stations must be physically located on land, or on non-tidal waterways, within the boundaries established by the continental shelves of Europe and North America. Each operator must be properly licensed as an amateur radio operator by his or her national government, and be operating within the provisions of that license (especially power and frequency limits). IRTS reserves the right to have its representatives inspect both claimants' stations to ensure that things are on the up-and-up.

The normal rules for an established ham QSO apply to the 2 meter Transatlantic Challenge. Both stations must receive the callsign of the other in full; signal reports must be exchanged (any recognized system—RS, RST, meteor scatter—can be used, but it must include at least two characters); each station must receive confirmation (Morse "QSL," "R" or voice "Roger") from the other. The data must be exchanged within a single four-hour period. If the four-hour period expires, then a new contact-pair (another four-hour period) must be established.

In something of a "shades of Marconi" effort, the Radio Society of Great Britain (Lambda House, Cranborne Road, Potters Bar, Herts., EN6 3JE, England) is setting up a special account for donations to its RSGB Propagation Studies Committee to allow the establishment of permanent beacons

on 2 meters. One beacon will be located near Lands End, England, and the other near St. Johns, Newfoundland. That project could result in some substantial propagation studies, and could lead to the information that will cause someone—or more than one someone—to win the St. Brendan Trophy.

For a good source of technical information on the problems of 2 meter transatlantic propagation, check out "How To Win The Brendan Trophies" by Dr. Geoffrey H. Grayer in the June 1995 issue of *Radio Communications* (*RadCom* is the journal of the RSGB, and thus enjoys a position similar to the ARRL's *QST* among British ham operators). The address for RadCom is the same as for the RSGB above).

"Here's your chance for immortality."

The Brendan challenge is not impossible, but it would be very difficult. One of my earliest ham writing tasks was the monthly report of the Northern Virginia Radio Club (club station W4PAY) to the Foundation for Amateur Radio's *Autocall* newsletter. As a result of that task, I received an invitation to the 1960 Edison Award (sponsored by General Electric) banquet in Washington, DC. The two fellows who won the award that year had established two-way ham contact on 2 meters between California and Hawaii. Not exactly the North Atlantic path, but about as far (although I would prefer being in KH6-land than in any location in the North Atlantic ... save only El-land and G/GM-land, for which I have a special fondness).

"Hams With Class"

One of my favorite ham columns has been "Hams With Class" in *73*, partially because I have a soft spot for people who work with kids and introduce them to radio in general and ham radio in particular. Every year I judge several science fairs, and am impressed with the ability of kids to do science and technology. A lot of them are little more than re-doing classroom demonstrations, or worse, but another big bunch is doing some real science (unfortunately, I won't be able to judge too many science fairs this year because I am teaching a Northern Virginia Community College class in Visual BASIC on Saturday mornings).

The point of this digression is that we hams have an opportunity to hook kids into the hobby at an early age through education. There are a couple of ways to go about this (besides reading "Hams With Class"). First, you can mentor (or is that "Elmer"?) youngsters who show interest in radio. That's how I got started (Mac Parker W4II was mine), and I suspect it's how many of you-all got started as well). Another way is to work with high school and junior high school science fairs, or volunteer to work with the science departments.

In some schools, they permit college-degreed members of the community to teach science classes, although under the supervision of a licensed teacher. That's a possibility for both community involvement and (in some cases) a little (very little, sadly) extra income. In other cases, even non-degreed people with industrial arts experience are allowed to teach shop classes (again, under a licensed teacher's supervision). An auto mechanic I know teaches a two-hour shop class every day at the local voc-tech school (a high school with an industrial arts flavor).

You can also set up demonstrations of ham radio for the school, or serve as a community advisor or mentor to a student ham radio club (I've seen both done).

Still another tactic would be to become familiar with radioscience observing, and integrate ham radio into it. This activity includes looking for natural radio signals such as whistlers (1 to 10 kHz), sudden ionospheric disturbances (SIDs) caused by solar flares (these are found by monitoring 15 to 30 kHz VLF stations for sudden increases in signal level), and propagation studies (especially during solar eclipses or other solar events). Ham radio can be "snuck into" such activities.

Still another way is to find and encourage schoolteachers who want to get into ham radio themselves. Mentor them, get them licensed, and help them set up a station. You do that with newbies anyway, so why not concentrate some advertising for your club's Novice class on the local schools? I recall a seminary professor who taught at a school that had a large contingent of Third World students on scholarship. He said the reason was that it cost $25,000 a year to keep a missionary in those countries, but only $10,000 a year to educate a national ... who would go back home and remain in place teaching for many, many decades (at no additional cost or effort). The same principle applies for hams: Teach a teacher how to "fish" and you won't have to feed his or her students yourself. Teachers, after all, are largely dedicated to their profession, and will perform admirably to mentor young hams-wannabees and help them get licensed. Putting a little effort into junior and senior high schools, not to mention the upper end of the elementary grades, will pay rich dividends for the hobby.

How important is getting more lifetime hams into the hobby? Radio spectrum is precious, and there is a simple rule in effect: Use it or lose it. Remember, the 11 meter Citizen's Band was a ham band pre-1957. We lost it to the Class D CB service because the FCC could see that very few people were using it ... the 1956 or 1957 "Save 11" contest at the last minute notwithstanding.

Connections ...

Good News—Bad News

We start the new year without AMSAT-OSCAR-13. This high-orbit, long-life satellite was launched in June 1988. Since then it provided hamsat enthusiasts quality high-tech communications for over eight years before succumbing to the gravitational effects of bodies beyond the earth. Most satellites in elliptical orbits with a perigee, or low point, of thousands of miles will stay in orbit for hundreds, if not thousands, of years. Due to the orientation of A-O-13's orbit, this was not the case. The forces of nature took over and its premature end was inevitable as its perigee was pulled closer to the earth by the sun and moon.

On the positive side, A-O-13 performed extremely well while in orbit. AMSAT-OSCAR-10, while not as functional as A-O-13 was before reentry, still provides high-orbit, Mode "B" (70 cm uplink and 2 meter downlink) operation almost 13 years after launch. Before launch, A-O-10 was known as Phase 3-B. It was the second Phase 3 hamsat. Its predecessor, Phase 3-A, never made it into orbit due to a rocket malfunction in early 1980. Excellent long-distance contacts are still possible through A-O-10 when conditions are right. The on-board computer no longer works, but the Mode "B" radios and the solar cells are doing well. When the satellite is properly illuminated, signals are good.

Phase 3-D coming soon

Amateur radio's next major satellite is scheduled for launch in April 1997. Named "Phase 3-D," this satellite is the largest, most complex and most expensive ham-radio satellite ever built. Volunteers in over a dozen countries on five continents have been working for years to bring this project to fruition.

The launch is to be the second ever for the new Ariane 5 rocket. The first Ariane 5 failed in June 1996. Corrections have been made, tests have been run, and optimism is high for the second flight. Phase 3-D will be sent up with a pair of technological measurement packages for validation of the launch vehicle's ability to place two satellites into a geostationary transfer orbit.

After launch, Phase 3-D will become an OSCAR (Orbiting Satellite Carrying Amateur Radio) and will begin a period of testing and orbital adjustment that may last months.

In the meantime...

Waiting for the new high-orbit satellite needn't be dull. We have over a dozen operational LEO (low earth orbit) hamsats in orbit available for use four to six times a day each, anywhere on earth. Frequencies used on these satellites range all the way from the 21 MHz uplink of RS-12 to the 2400 MHz downlink beacon of Dove-OSCAR-17. There is a good mix of digital and analog (voice/CW) satellites available. We have new satellites like Fuji-OSCAR-29, launched only a few months ago, to older satellites including UoSAT-OSCAR-11 launched in March 1984.

The South Africa AMSAT Award

In a cooperative effort with Southern Africa AMSAT, the Radio Amateur Satellite Corporation (AMSAT-North America) is promoting the South Africa AMSAT Satellite Communication Achievement Award. This award is the perfect entry-level award for satellite enthusiasts. The requirements are simple. Send 25 QSLs (or good front and back photocopies) for Phase-2 (low earth orbit) satellite contacts to the AMSAT Awards Manager. The fee is $3.50 for AMSAT members and $5.00 for non-members. Additional funds are requested for the return of QSL cards if photocopies are not submitted. Send to: AMSAT Awards Manager, Mike Scarcella WA5TWT, 310 Lombardy, Sugar Land, TX 77478. Mike has been authorized to issue the South African award without the long delays previously encountered with overseas submission. The low-orbit hamsats can be a lot of fun.

A New Year's event

For many years the ARRL has sponsored Straight Key Night (SKN) on New Year's Day. Ray Soifer W2RS invites interested satellite operators to participate in the 25th annual SKN via OSCAR. He reports that there are no rules, no scoring, and no need to send in a log. Just call CQ SKN in the CW passband segment of an OSCAR between 0000 and 2359 UTC on January 1, 1997, or answer a CQ SKN call from another station. Contacts via the moon also count. Ray refers to the moon as OSCAR-0. Nominations for the best "fist" can be sent via the Internet to w2rs@amsat.org.

An end before a beginning?

Less than a month after the successful launch of Fuji-OSCAR-29, Mexico-OSCAR-30 (M-O-30) was successfully placed in orbit from the Russian Plesetsk facility on September 5, 1996. The satellite's polar orbit is just under 1,000 kilometers (600 miles) high. Signals from the satellite were received shortly after launch, but there is a problem. The signals disappeared after several days and attempts to command the satellite failed. Work continues in an attempt to bring M-O-30 back to life, but catastrophic failure in the command receiver is feared.

Prior to launch, the new satellite was called UNAMSAT-B. This was not the first UNAMSAT, but rather the replacement for UNAMSAT-1 which never achieved orbit. The UNAMSAT-1 launch attempt on a converted Soviet SS-25 (TOPOL) missile met a fiery end when an upper-stage motor failed on March 28, 1995. Following the disaster, the UNAMSAT crew was dejected but not without hope. Two sets of spacecraft modules were originally built.

While UNAMSAT-1 lay in a mass of rocket debris somewhere in eastern Russia or on the bottom of the Sea of Okhotsk, the back-up modules were waiting safely back in the lab in Mexico City. It took a lot of work over a one-year period to get the second UNAMSAT ready—to buy new solar panels and get another ticket to orbit. Project Director David Liberman XE1TU provided the needed drive. UNAMSAT-B represents the never-say-die attitude of true space pioneers.

UNAMSAT-B

Built at the Universidad Nacional Autonoma de Mexico by the PUIDE (Programa Universitario de Investigacion y Desarrollo Espacial, or University Program of Space Research and Development) group, UNAMSAT-B is the most recent

Uplinks	Channel A	145.815 MHz - 1200 baud AX.25 FSK
	Channel B	145.835 MHz - 1200 baud AX.25 FSK
	Channel C	145.855 MHz - 1200 baud AX.25 FSK
	Channel D	145.875 MHz - 1200 baud AX.25 FSK
Downlinks	UHF TX1	437.206 MHz - 1200 baud AX.25 BPSK
	UHF TX2	437.138 MHz - 1200 baud AX.25 BPSK

Table 1. Band plan for Mexico-OSCAR-30.

microsat "clone." The first microsats were launched six years ago from French Guiana. They are small cubes, 25 cm on a side, weighing about 10 kg each, with five internal stacked modules. Four of the modules contain standard systems common to all AMSAT microsats; a five-channel 2 meter receiver, battery charge regulator unit, computer and 70 cm transmitter. The fifth module in the stack is called the TSFR, or "This Space For Rent." The TSFR in M-O-30 contains an intriguing experiment to identify meteors that have velocities greater than 72 km/sec.

The five-channel, 2 meter receiver was designed for digital (1200 baud FSK AX.25) uplinks from users on four simultaneous channels: 145.815, 145.835, 145.855 and 145.875 MHz. The fifth channel is the unpublished uplink for ground-based control stations. It is used to send software up to the satellite and change onboard operational parameters. A failure in the command receiver is one of the possible reasons for M-O-30's silence.

The BCR module, or battery charge regulator, contains not only the power control circuitry, but also the nickel-cadmium batteries that allow the satellite to operate during eclipse periods.

The computer module uses a radiation-hardened NEC V40 microprocessor. There is also a 256 Kbyte bank of EDAC memory and an additional 4 Mbyte bank of SRAM. Total computer-system power consumption is under 1 watt.

The transmitter module contains two separate UHF transmitters for telemetry and communications downlink. Both use BPSK (bi-phase shift keying) modulation at 1200 baud, AX.25 protocol. The primary transmitter is on 437.206 MHz, and the secondary transmitter is set to 437.138 MHz. Only one transmitter at a time is activated, but either can be used for all telemetry and data communication purposes.

The body of the satellite is surrounded by high-efficiency gallium-arsenide solar cells and a thin quartz crystal coating. The 2 meter antenna is on the top, while the 70 cm antennas are arranged around the bottom. The 41 MHz antenna is a canted dipole.

The TSFR module

Packed into the fifth module is a 70 watt (RMS) radar transmitter on 40.997 MHz, a sensitive receiver and a computer. The transmitter sends short pulses (1 to 16 ms) every one to 16 seconds. The 41 MHz transmitter is licensed by Mexico according to the ITU (International Telecommunications Union) frequency allocation listings. The receiver then listens for echoes from ionization trails caused by meteors as they burn up in the atmosphere. The returning echoes are digitized, analyzed by the computer and then downlinked as data files on 70 cm for study.

In order to provide the temporary but high current needs of the radar transmitter, special buffering on the 10 volt satellite power bus was required. A special switching power supply was designed to charge a bank of 16 tantalum capacitors to 40 volts between pulse transmissions. The system does not overload the main power bus and has a DC-to-RF efficiency of 92 percent.

The 41 MHz receiver is a single-conversion design with both lower and upper sideband detectors. Total bandwidth is about 20 kHz, enough to handle the maximum Doppler shift expected from returning meteor-trail echoes.

For meteors, 72 km/sec is the solar system escape velocity. Meteors traveling faster are from outside our system. The TSFR computer (68HC805 microcontroller) records the received echo from the receiver and then sends it to the main satellite computer module as a 64 byte block for further analysis and subsequent transmission via the downlink transmitter. The analysis includes a Digital Fast Fourier Transform (DFFT) and a special buffer system to check for Doppler shift between subsequent received signals. If Doppler shift is detected between the samples (indicating relative meteor speed), the radar transmitter will be set for a faster pulse repetition rate for a period of time. Data that represents meteors traveling above the 72 km/sec speed limit will be logged and stored in files.

Communications

The frequencies shown in **Table 1** define the Mode "J" communications capabilities of M-O-30. The following data was received by Norbert Notthoff DF5DP a few days after launch on the 70 cm downlink before the satellite went silent:

UNMSAT-1>STATUS:?12S f<-
UNMSAT-1>PUIDE:

AFTER ALL IT STILL MOVES......
Y A PESAR DE TODO SE MUEVE....

UNAMMEXICO.
UNMSAT-1>BCRXMT:%?12
UNMSAT-1>TIME-1:PHT: uptime is 005/10:32:41.
Time is Sat Sep 07 18:17:29 1996

More information

Additional information about the M-O-30 and efforts to bring it back to life can be easily found on the Internet. The best source is from the AMSAT World Wide Web site. The URL (Universal Resource Locator) is: http://www.amsat.org. M-O-30 bulletins and updates, along with orbital elements for tracking programs, can be found and downloaded. The AMSAT site provides a link to the UNAMSAT web pages, or you can address them directly at: http://serpiente.dgsca.unam.mx/unamsat/unameng.htm. M-O-30 held much promise both as a fun satellite and as an exciting experiment. If efforts to bring it back fail, let's hope that the UNAMSAT team will try again.

Ham to Ham

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

With the first issue of the new year comes a nice variety of "Ham To Ham" tips. Many thanks to those who've taken the time to send in their ideas (often several) during 1996, as well as to the names that we're seeing for the first time. I'm always looking for more tips, ideas, suggestions and shortcuts to keep the column going and growing, so please don't hesitate. The address is above.

Adjustable antenna tip

From William Thim Jr. N1QVQ: Bill has been very supportive, with a number of good tips. "I own a portable antenna that covers several VHF/UHF ham bands, but it must be physically adjusted for each different band. After losing the adjustment instructions once, I decided not to let that happen again, so I got the tuning instructions from a friend, then transferred them to the antenna's base using a customizable rubber stamp kit like the ones sold in many office supply stores. A coat of clear lacquer spray over the stamping sealed it. To make sure that I always had a tape measure with the antenna for those critical adjustments, I made a trip to the XYL's favorite sewing supply store and purchased one of those 'cloth-tape yardsticks,' attached it to the antenna using a 'twist-tie,' and now I know I'll have everything needed for adjusting the antenna. You can 'customize' this basic idea to fit your own antenna-element needs, depending upon the particular model of adjustable antenna that you have."

Moderator's note: Good idea, Bill; also, don't forget to "twist-tie" that special Allen wrench or an inexpensive small screwdriver to the package if loosening and tightening set-screws is involved in the adjustment. A small, plastic "zip-lock" bag with a hole punched into one corner can hold these odds and ends. The bag itself can then be secured to the antenna package with a "twist-tie" or short length of cable-lacing twine.

Not written in stone

From David Hyman KBØONF: A way to cut down on paper costs in your ham shack: "I've been able to drastically cut down on the amount of scratch paper that I use by assigning the note-taking task to a scrap piece of 1/4" thick, 8 1/2" x 11" chunk of white Plexiglas™ instead. Smooth white Plexiglas is available from surplus outlets around the country at very reasonable prices ... often sold by the pound (look in your Yellow Pages under 'surplus-retail'). It can be easily cut with a bandsaw, or simply scored with a utility knife, then cracked over the sharp edge of a table—the ragged edge can then be either filed or lightly 'fire-polished' with a propane torch (go easy, it doesn't take much heat).

"The white Plexiglas is then the 'perfect' writing surface for either dry marker pens or the water soluble pens sold in art stores and office supply outlets. I prefer the 'dry markers' myself, one of which is the Expo Markaway 3™. No. 83000, by Sanford. Black is probably the best color and a chisel-shaped tip works nicely for me.

"Cleaning the white Plexiglas surface after use is easy too. A dry erase spray cleaner is sold specifically for this purpose, but I've found that lacquer thinner, poured into a defunct glass window cleaner spray bottle, works just as well and at a fraction of the cost. The lacquer thinner doesn't seem to attack or soften the white Plexiglas that I'm using in any way."

Moderator's note: I've used a similar idea in my own ham shack using a "note jotter," consisting of a washable pen and plastic-coated tablet, made for wall hanging near a kitchen telephone. In this case, a damp cloth will erase everything. Remember those little marker slates with a clear plastic on top, followed by a translucent sheet and ending with a black waxy surface? You simply lifted the two top sheets to erase the whole tablet ... great fun to use as I remember.

Considerable cable considerations

From Phil Salas AD5X: "I'd suggest that you consider using 9913 coax cable, instead of the more popular RG-213, for your VHF/UHF antenna feedlines. 9913 has about a third less loss than RG-213 at a given frequency, and is much easier to 'connectorize' with the standard PL-259 UHF connectors. The inner insulation is easier to strip since it is mostly air! The shield is easier to solder to the PL-259 since the inner dielectric doesn't conduct the heat away as it does in the RG-213 type of cables. Cable X-perts (orders 1-800-828-3340, tech inf. 1-847-520-3003) sells 9913 for 42 cents per foot, which is only about six cents per foot more than RG-213. The disadvantages: You must take extra care to properly waterproof your outside connectors (since any internal water will flow easily through its mostly air-filled innards) but you should carefully waterproof all outside connectors anyway. Also, 9913 is not quite as flexible as RG-213, since the center conductor is a solid copper conductor. A stranded center conductor form of 9913 is available, but it's a bit more expensive ... the choice is strictly up to you.

"For waterproofing those outdoor connections and connectors, I've had very good luck with a product called Plast-Dip™. It's a fast-curing liquid plastic material that's intended primarily for coating tool handles. A can of the thick liquid costs about $7 at Home Depot™ and other hardware and home centers, but it should last you a good long while. I usually put two coats of it on all of my outdoor connections. For wire connections, such as separating a coax shield and center conductor for feeding a dipole antenna, I immobilize the point where the shield and center conductor separate, using hot glue (hot glue guns are great for lots of things). Then I attach solder lugs to the ends of the shield and center conductor—where attachment to the antenna will take place. Finally, I dip the entire end (including the solder lugs) into the Plast-Dip and let it cure. After curing, I use a sharp hobby knife to trim off the excess Plast-Dip insulation that covers the ends of the solder lugs. Neat, easy and very waterproof!"

Moderator's note: Good suggestions, Phil. Waterproofing outdoor coax fittings can't be overstressed; any moisture in even the solid insulation coax is disastrous. The shield of a coax must appear as a solid conductor to RF; that is, each overlapping strand of braid must touch as many of its neighboring strands as possible, seeming to be a solid outer pipe. Water of any sort inside the coax jacket spoils this shielding quality (and you can't tell it by DC resistance checks alone—it must be tested with true RF testing, looking for loss or leakage). Even a small nick in the outdoor cable's jacket must be re-sealed. Phil's suggestions on the best (lowest loss) cable are also well taken. Even if your entire cable run can't be of a low-loss variety,

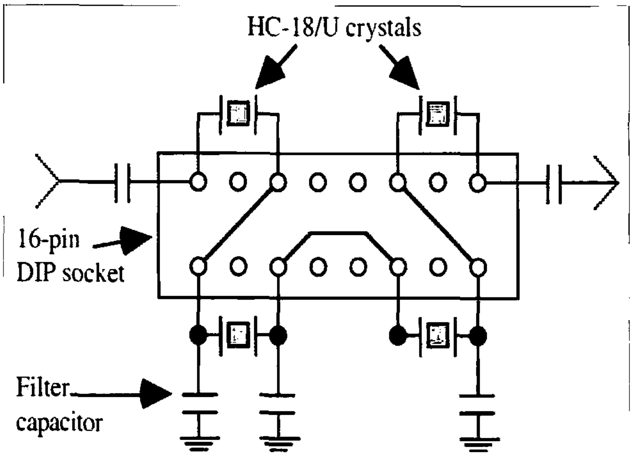

Fig. 1. KB4ZGC/W4LJD'S idea of how a four-crystal ladder filter might be laid out using a standard 16-pin DIP IC socket for mounting the crystals.

every foot that you can manage will be that much better.

Crystal DIP

From J. Frank Brumbaugh KB4ZGC/W4LJD: "When constructing crystal ladder IF filters, you can save PC board space, simplify the layout time and make the crystals much easier to check or replace by simply using a standard 16-pin DIP socket to hold the four crystals needed. Interestingly, the HC-18/U style of crystal with wire leads will plug in directly across three pins of a standard DIP IC socket. A quick look at **Fig. 1** will illustrate how a four-crystal filter would be wired using this scheme. Just clip the HC-18/U's leads to about 1/4", then plug in the crystals after all of the heat-producing soldering has been done. If you need more than four crystals, just add another DIP socket!"

Moderator's note: Clever idea, Frank. By the way, Frank's right, a wire-lead HC-18/U fits perfectly across three pins of a normal DIP socket. I'd recommend using the best DIP sockets you can afford for this application. The ones with round "machined" pins hold the crystal nice and tightly.

Murphy's Corollary: When working out a problem on a specific piece of equipment, try sleeping on it... it's sure to make an impression!

Many thanks to this month's contributors. Without your continued input, I'd soon run out of ideas. Please keep them coming.

NEVER SAY DIE

Continued from page 33

in with catcalls, carriers, and jamming, but without signing calls.

If I were an advisor for any company wanting to get the use of a ham band for their products, I'd record and edit a few days of this kind of crapola as proof that there clearly are much better public uses for the billions of dollars worth of ham spectrum we've inherited and are laying to waste. Since we claim to be self-regulating, we have no valid excuse for allowing this kind of sickness to go on.

So why are cesspools like that poisoning our hobby? It seems to me this is largely the result of a lack of credible leadership from our one (and really only) national organization. The pathetic weakness of our ARRL leadership has left amateur radio in a similar situation to a leaderless country like Somalia. This weakness starts right at the top: the ARRL board of directors, which you continue to re-elect. My bumper sticker Never Re-elect Anyone (the NRA for the '90s) should be not just applied to Congress, to help flush out

Continued on page 56

NEVER SAY DIE

Continued from page 55

that mess, but also to your ARRL board of director rubber-stamp voting every other year. Keep flushing until we get some young people in there and see signs of leadership beginning to show.

How will you know? When you see signs that the League is attacking messes like 14,313, K1MAN's endless ego gratification, the lack of youngsters coming into the hobby, our overall lack of growth (except for no-coders), the disinterest of the no-coders in upgrading, and stuff like that.

Amateur radio got grandfathered into most of our present ham bands as a result of the pioneering work hams did in the earliest days of radio. Then we held on to most of our bands by providing clearly visible public services. Amateur radio was often the only means of communicating in emergencies. And, as I keep mentioning, 80% of the licensed hams went into the military for WWII, providing a priceless contribution to our winning the war, in which radio, radar and sonar were critically important.

But today, due to an almost total lack of leadership, we are no longer the pioneering group we once were. We no longer are of any value whatever to the military in case of a war. Even our vaunted emergency communications are disorganized and being made irrelevant as other communications services are passing us by. The only hope I can see for our survival is as a way to help get kids interested in high-tech careers, the way we did before the ARRL virtually stopped youngsters from entering the hobby 33 years ago. We *have* to provide some sort of visible public service if we're going to hold our ham bands, which are worth tens to hundreds of billions today. But without leadership it's only a matter of time, and I doubt that we have much of that.

But how about the FCC—won't they protect us? Why should they? These days we are nothing but a royal pain in the butt and an additional difficult-to-justify expense for an outfit whose budget is being cut back, year after year. Instead of putting the pressure on the ARRL to solve our problems we write to the FCC, demanding help. When nothing comes of that we write to our Senator or Congressman, asking him to put pressure on the FCC to help. And he then sends a copy to the FCC, pushing for action. And since there is little the FCC can do, they just want to stop the pain.

What would you do if you were a politically appointed FCC commissioner? You know little about the history of amateur radio. All you know is that there is a disorganized bunch of old (very old and largely lower middle class) white men who are enjoying billions of dollars worth of the spectrum which they inherited when it was of no value and are these days contributing little in return. All you get is complaints—about interference, bad language, repeater coordination, and so on. Try sitting in a commissioner's chair for a minute and see how that feels.

If you feel that I'm dumping on the ARRL about all this, then please let me know who you recommend to help solve our problems? If you really don't believe our leaders have no responsibility to lead, then what alternative do you suggest? If you don't have an answer, ask your director and then let me know what he proposes.

Or should I start work on a book, *Ham Radio — In Memoriam*?

Professors and Beards

Have you ever noticed how many professors wear beards? Maybe there's a good psychological reason for this. Try on my reasoning and see how it fits.

What has teaching college got going for it? Short hours, lots of prestige, tenure (you can't get fired), paid sabbaticals, and generous retirement benefits. No, you'll never make a lot of money, but the security is a trade-off. And the prestige. They sure play *that* game. Doctor. Professor. Distinguished Professor.

Now, if you were a person with low self-esteem, also known as an inferiority complex, you would tend to look for work where prestige is flaunted. Low self-esteem people can't help but do everything they can to make others think they are important.

But they also tend to want to hide their faces. I went to a costume party when I was a kid. My mother made a Shadow costume for me, complete with a black veil. That was the first time I'd ever been at a party where my face was hidden, and wow, did that feel different. Suddenly I was very outgoing and the life of the party. A veil or mask gives one a sense of security. And so does a beard to hide behind. Think over the bearded people you know and see if you think I'm right.

The only bearded guy I can think of that this doesn't fit was Sam Harris W8UKS/W1FZJ/W1BU, but then he wore his in the '40s and '50s, back when that was an outrageous thing to do—which was why he did it. He didn't just wear it, he flaunted it.

Vegetizing

Unless you've chosen to be uneducated in the food department (aka ignorant), you know that you really should be including a hefty bunch of veggies to your diet. At least if you want to make it with any grace through your 50s and not join the strictly steak and potatoes group in their $2,000-a-day hospital wards. Yes, I know, you and Bush are not broccoli fans. I happen to like it, but I can almost empathize with those who don't. When I was a kid I hated cauliflower and didn't think I'd ever like it. Now I love it.

Anyway, I've found a great way to not just make these veggies delicious, but to do it in their healthiest (for you) form: raw. Here's the deal. I hope you have a blender. I throw in a cup each of raw broccoli and cauliflower, and a half cup of raw carrots. Zizz 'em together until they're in pieces slightly smaller than Grape Nuts.

You're going to need some salad dressing for this. I'm using a couple of tablespoons of my old coleslaw recipe. It has two parts extra virgin olive oil, two parts apple cider vinegar, one part honey, one part mayonnaise, six parts plain yogurt, a teaspoon or two of celery seeds, salt and pepper to taste. Then whip it all together. This makes a fabulous sweet-sour dressing that's great for slaw and as a veggie dip. It's reasonably low cal and easy to

Radio Direction Finding

Joe Moell P.E. KØOV

Fullerton, CA 92637

A Foxhunting Jamboree

When did you first hear about radio direction finding (RDF)? Since it has become a tool for finding downed aircraft and stolen cars, today's school kids probably get a vague notion of it early on. Sadly, they aren't told that it can also be great fun for them.

A recent E-mail exchange with Tom Stewart K3TS brought back memories of my introduction to RDF. Tom wrote a classic article about 2 meter hidden transmitter hunting in New Jersey for the September 1957 issue of *QST*. I was 10 years old at the time and studying for my ham ticket, faithfully trying to copy W1AW code practice every night on my drifty Hallicrafters S-38D receiver. That *QST* issue was one of my first ham radio magazines. Tom's tales of T-hunt trickery got me eager to try the sport.

When my Novice license arrived the following spring, I agitated at the radio club in our town of 11,000 souls to get the group to hold some hidden transmitter hunts. Even though Novices had 2 meter phone privileges at the time, we were a hundred miles from the nearest 2 meter activity and there were no repeaters to bridge the gap.

Finally, the club scheduled a hunt on 75 meter AM, where most mobile operating was done in those days. I somehow managed to lash together a two-tube 75 meter converter with vibrator power supply and connect it to the broadcast receiver in the family's gas-guzzler convertible. Of course I had to talk Dad into driving. Bemused by the whole thing, he agreed.

For an RDF antenna, I used the multi-turn flat loop from the back cover of an old table model broadcast set. I hadn't learned enough RF theory to do a good job of resonating and coupling it, so it wasn't very sensitive or directional. Dad and I did a lot of riding around just trying to hear a signal over the ignition noise. Fortunately, the hunt boundaries were small and gas was cheap.

Hundreds of T-hunts later, I still think it is the most fun you can have in ham radio. I wish every youngster could experience it. But how many kids nowadays have supportive radio clubs and patient fathers to Elmer them into it? How can we bring kids and RDF together? I think "Homing In" readers Greg and Gabriella Owens (WA6HKM and KE6JQS) have found an answer.

This campground welcomes foxes

Greg and Gabriella's letter arrived shortly after Labor Day. They were in charge of a committee from the Simi Settlers Radio Club that would be hosting a Scout Jamboree-on-the-Air (JOTA) campout. They wanted to know how to put on a demonstration of foxhunting (also called radio-orienteering and ARDF) as part of their JOTA activities. What an opportunity!

JOTA is a worldwide ham event, held annually in mid-October for almost 40 years. Having never been in Scouts, I knew very little about it. I had no idea if foxhunting had ever been done there before. (Actually, I'm still not sure.) Either way, I knew that this opportunity couldn't be passed up, so I called them immediately.

JOTA celebrations run for a 48-hour period beginning Friday afternoon. They range from simple to elaborate. In some towns, a ham invites a troop or two for a ham shack visit, letting Scouts participate in contacts with other JOTA groups. In other places, it's a full-blown Camporee with many stations and activities. That's what the Settlers were planning.

"We hope to have stations on every active HF and VHF band," Gabriella told me. "We'll demonstrate both voice and CW modes on the air. Local ATVers will set up two stations so the Scouts can have television QSOs back and forth. We will also have code oscillator kits for them to solder together."

Photo A. April WA6OPS helped explain RDF to eager Scouts before they went out to hunt. Looking on is longtime Scouting supporter Darryl Widman KF6DI. (Photo by Joe Moell KØOV.)

The Simi Settlers' JOTA site would be Lake Casitas Recreation Area near scenic Ojai, California. Scouts from Ventura, Los Angeles and Santa Barbara counties were invited. Several hundred could be accommodated. The event would officially begin at noon Saturday and continue for 24 hours. Many Scouts would camp over Saturday night, while others would be at the lake shore for just a few hours on one day. Foxhunting at night would be unsafe, so we had to make it possible for many Scouts to hunt at the same time during our limited available hours.

Lake Casitas is a drive of over 100 miles for T-hunters in my area, but it is only about 40 miles from Santa Barbara, where there is a growing group of radio-orienteering enthusiasts. I own plenty of fox transmitters, but not enough RDF gear for dozens of Scouts to use. What's more, April and I would need knowledgeable helpers for one-on-one training of the Scouts. I zipped off E-mail to Marvin Johnston KE6HTS of the Santa Barbara Amateur Radio Club and he immediately agreed to help.

Having no experience with foxhunting demonstrations for pre-teens, I could only try to envision how it would go. I imagined that we would take the Scouts in packs or troops of a dozen or two and give them a quick show-and-tell on RDFing and map plotting. Then we would hand out some gear and send them into the woods to try to find five foxes transmitting for a minute each in sequence, just like they do in a formal international-rules competition (see "Homing In" for August and September 1996).

Greg surveyed topographical maps of the site and suggested a hilly area of about one square mile across the park road from the camping area. He even agreed to make lots of copies of that map for the Scouts. "Don't worry," he told me, "they are prepared for being in the woods and will bring compasses with them." Good, all I would need for orienteering would be a batch of protractors.

For a week before the event, I spent each evening tuning up my RDF sets and borrowing more. On Friday afternoon, April and I went to the site to check it out. I quickly realized that my imagination had not served me well. The hilly area was fenced off. No access! Oh well, it wasn't very shady. In truth, it looked like a barren home for rattlesnakes. Besides, it was too far away from the campsite.

We decided to hide the foxes within the large wooded JOTA campground, not far from our van where we were showing a video of international radio-orienteering competitions (see **Photo A**). Scouts would not have a long hike. We could easily watch and help. As a side benefit, the sight of them combing the grounds with sniffing gear would attract much more attention to our demonstration.

The two hundred or so Scouts that came to Lake Casitas were mostly in elementary school. They may be champs at the latest video games, but they had to start at square one when it came to RDF. No way could we simply slap gear into their hands and send them out. It worked best to guide them along in groups of two or

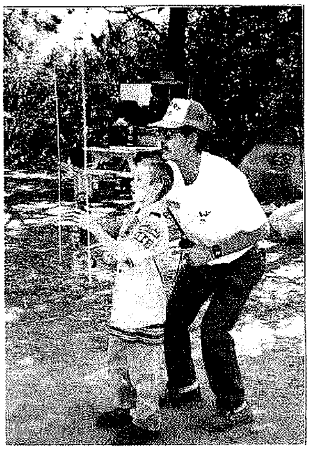

Photo B. Reg Reginato KE6ZQY of Santa Barbara shows a Scout how to use his dual-dipole TDOA RDF set in the JOTA-96 campground. (Photo by April Moell WA6OPS.)

three as they learned. One Scout at a time used the RDF set while the others watched. It would then be their turn to find the next foxes.

Five cycling intermittent transmitters proved to be too confusing during the learning process. We changed two of them to be continuous emitters on separate frequencies below 146 MHz, just for first-timers. One was in a surplus ammunition box while the other was the cleverly camouflaged "stud T" (see "Homing In" for October 1996). That one always got looks of amazement when the Scouts flushed it out. As time and equipment permitted, those who did well on continuous foxes could try to bag the intermittent ones on 146.565 MHz.

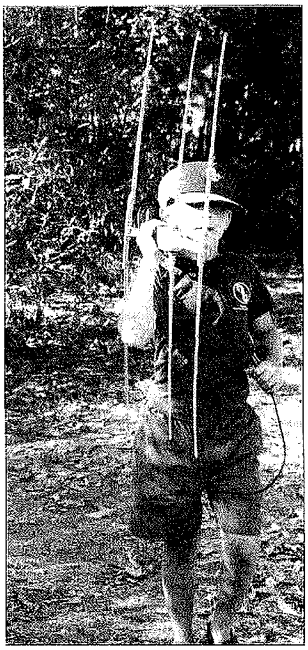

Photo C. To this Cub Scout, RDF gear seems a bit heavy after a few minutes of fox tracking. Next time, I'll add a mast so this Russian-made set can be held high more easily. (Photo by Joe Moell KØOV.)

Better tools needed

To regular users of VHF-FM, it's easy to gauge the strength of incoming signals by the amount of background hiss, or lack of it (quieting). But to a Cub Scout who has never held a handie-talkie before, it's not obvious. After some practice, a few of them did well at getting bearings with an HT, beam and active attenuator. Others couldn't seem to get the hang of it, especially if the HT didn't have an S-meter.

Other types of RDF sets were much easier for kids to learn. The Santa Barbara group brought several dual-dipole homing sets (TDOA type) with left-right indication (meter or LEDs). Although TDOAs are more prone to multipath bearing errors and they lack signal strength indication, the kids found them easy to learn and had good results (see **Photo B**).

In Europe and Asia, where radio-orienteering is a popular sport in schools, everyone uses special amplitude-based RDF sets for 2 meters. There are many variations, but they all incorporate a yagi or phased array antenna and a built-in receiver with wide-range RF gain control. Signal strength is indicated by a panel meter, tone pitch, or tone loudness.

I had only two of these foreign-made sets along, but I think they were easiest for Scouts to learn to use. All they had to do was turn the antenna for strongest signal indication and walk that way. Their excitement grew as signal strength rose and they had to lower the RF gain; it meant they were closing in. Bearings were nearly always accurate.

Weight was the biggest disadvantage of the integrated receiver/antennas. It surprised me how difficult it was for some grade-schoolers to hold a three-element 2 meter yagi overhead long enough to hunt down a hidden fox. Their arms would become fatigued in about three minutes and the beam would slip down to shoulder height (see **Photo C**). Of course that adversely affected the beam's sensitivity and directivity. In the future, I want to have lighter antennas with masts, so they can easily be held overhead.

Photo D. Who says Morse is dead? Another hit of JOTA-96 was this code oscillator kit project. (Photo by April Moell WA6OPS.)

Competitive foxhunters prefer using earphones to hear fox modulation and strength tones in noisy surroundings. That's why most foreign-made integrated receiver/antennas don't have speakers. But phones aren't ideal for one-on-one training. My solution was to have the trainee wear them around the neck instead of over the ears. With gain turned up, they put out enough audio for the trainer, the trainee, and observers to hear. As a bonus, this eliminated the chance of an audio blast directly into the ears if the RF gain control was improperly set when the fox came on the air.

More "fox people" needed

ARDF and kit building were smash hits at our JOTA operation. Lots of Scouts were beeping away on their newly-built code oscillators as they came up to the foxhunting display (see **Photo D**). Some older Scouts said they'd had lots of HF QSOs in previous years, so they were glad to have some new activities this time.

Most Scouts had an opportunity to track at least one fox Saturday afternoon. Darkness fell around 6 p.m. and it was time for a big spaghetti dinner around the campfire. Then we left them for the night, promising to charge up the fox batteries for more hunts the next day.

If there was any doubt that foxhunting enthralled the Scouts, it was dispelled Sunday morning. As we pulled into the campground, we were greeted with young voices shouting, "The fox people are here!" Before we could get the RDF gear out, were mobbed. Scouts who had hunted on Saturday wanted to try again, because the foxes were all in new locations. We gave first priority to those who had not gotten a chance to hunt Saturday; then we let the rest have at it again.

Hats off to the Simi Settlers Radio Club for going beyond the call of duty in providing a special JOTA experience for the Scouts. Special kudos to Greg and Gabriella for paving the way for ARDF events. Also thanks to foxhunting enthusiasts from the Santa Barbara Amateur Radio Club for helping. In addition to Marvin, they were Stephen Nelson KD6VEX, Nerella Reginato, Reg Reginato KE6ZQY, Brian Peddicord KF6DZN, Mike Peddicord KE6OTM, Scott Phillips KF6EDD, Hubert Stamps KC6NAH, Bib Ummels KE6WYA, and President Darryl Widman KF6DI.

Many Scout officials at JOTA-96 expressed interest in future foxhunting demos and activities for their dens, troops, and packs. Given enough inexpensive equipment and trained leadership, radio-orienteering could become a mainstream Scouting activity. I have lots of ideas for gear. But will Scouting organizations across the country be able to find enough T-hunters to get this program off the ground?

Are you "Homing In" readers willing to build and stockpile some kid-proof ARDF gear, seek out your local Scout leaders, and put on training sessions? I want to hear constructive opinions and ideas from both T-hunters and Scout leaders about this concept. Let's prove that we mean it when we say we want more young people involved in ham radio activities. Send E-mail to Homingin@aol.com or write to the address at the beginning of this column.

NEVER SAY DIE

Continued from page 56

make. If you use a half cup measuring unit you'll use one quart of yogurt and end up with about two quarts of dressing.

The olive oil is good for you, as are the apple cider vinegar, honey, and yogurt. The best part is that this helps you live longer so you can watch while your enemies die of heart attacks, cancer, and other eating diseases. Heh, heh.

The combo of the raw zizzed veggies and slaw dressing makes eating health food easy. Hey, give it a try. It might help keep you from becoming a veggie.

Government Control

The religious fervor over abortion, pro and con, seems to have blinded both sides to the realization that once they get the government involved in religion, they have started on the slippery slope toward the government domination and control of religion. Is that really what they want? The old camel's nose in the tent syndrome?

The pro-lifers want to use the government to force their beliefs on everyone, backed by our so-called "correctional system." The pro-choicers want to force *their* beliefs on everyone, via government control. If either side wins, we all lose.

The same holds for school prayer. The damned judges should stop trying to get involved with religion vs. the government. Heck, I sat through school prayers for years without being impacted one whit. It was one of those rituals which we did without thinking, like saluting the flag, which we used to do every day. You know, that "One

A 1296 MHz Amplifier/ Mixer for Converter Use

With the coming of the new year and the holidays behind us, it's time to start getting our microwave and other projects off the back burner and start putting them together. Winter affects us in varying ways, with our many states and their vastly different geographical settings. For us here on the West Coast it means putting on a heavy shirt or light jacket for the chilly mornings, or getting prepared for our rainy season.

For other parts of the country with much harsher weather conditions this is truly the time for evening workbench projects. Last month we covered several older 2 meter multimode rigs, showing their use in SSB and narrowband FM operation as a lower-frequency IF system. This IF system is the heart of this RF converter, needing only a mixer, filter and local oscillator as additions for construction of a 1296 MHz converter.

Construction

This rig was quite easy to construct. While it is a peanut whistle (low power: +10 dBm), it is a complete rig needing only a local oscillator for operation. The beauty of this approach was that all the amplifiers are part of existing circuitry that is readily available. This circuitry requires only assembly into a shielded box to house the mixer, amplifier PC boards and relay switching circuitry.

This project was started when I tried to put together PC boards using MMIC amplifiers like the MAR series. This meant that I would have to come up with a PC board layout and select amplifiers to perform the receive and transmit functions of a low power RF controller. It was also intended to drive the transverter with a 2 meter multimode rig as the IF system in this project.

After several cuts at breadboarding this project I discovered that I did not need to construct amplifier chains as they were already at hand. The amplifiers came from Qualcomm surplus IF amplifier PC boards that I had available. They were originally a receive IF amplifier and a transmit IF amplifier using multistage MMIC amplifiers. Their small size, high gain and output power capability (+10 dBm on transmit) made them a very good candidate. The first breadboard test circuit was built using these IF PC boards, with a few other parts tossed in. These were simple RF relays, switching a mixer for converting frequency and a simple power supply regulator. Having all the material at hand and in modest quantity, allowing for others to use it, made this approach a natural for repeatability. First I had to construct a working model to prove that miniature inexpensive relays would function at 1296 MHz, thus eliminating expensive coaxial relays for low power switching.

I wanted used small surplus miniature SPDT relays removed from junk PC boards to switch the DC control voltages and the input and output RF switching as well. I was hoping that the RF losses would not

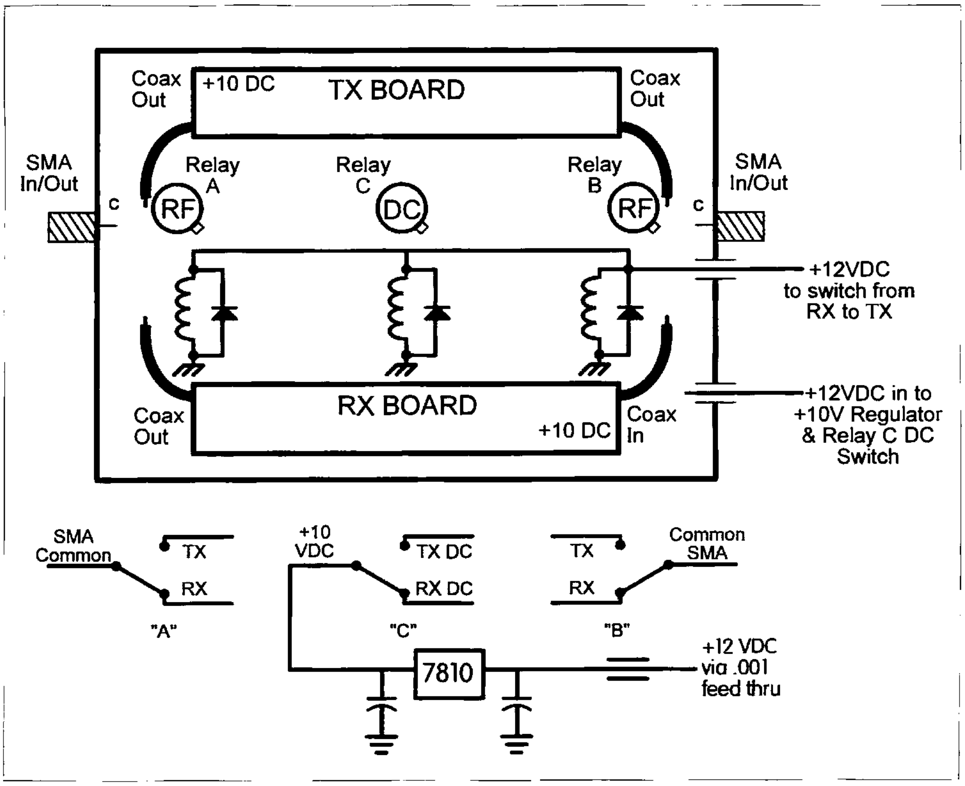

Fig. 1. Layout diagram of the amplifier converter unit.

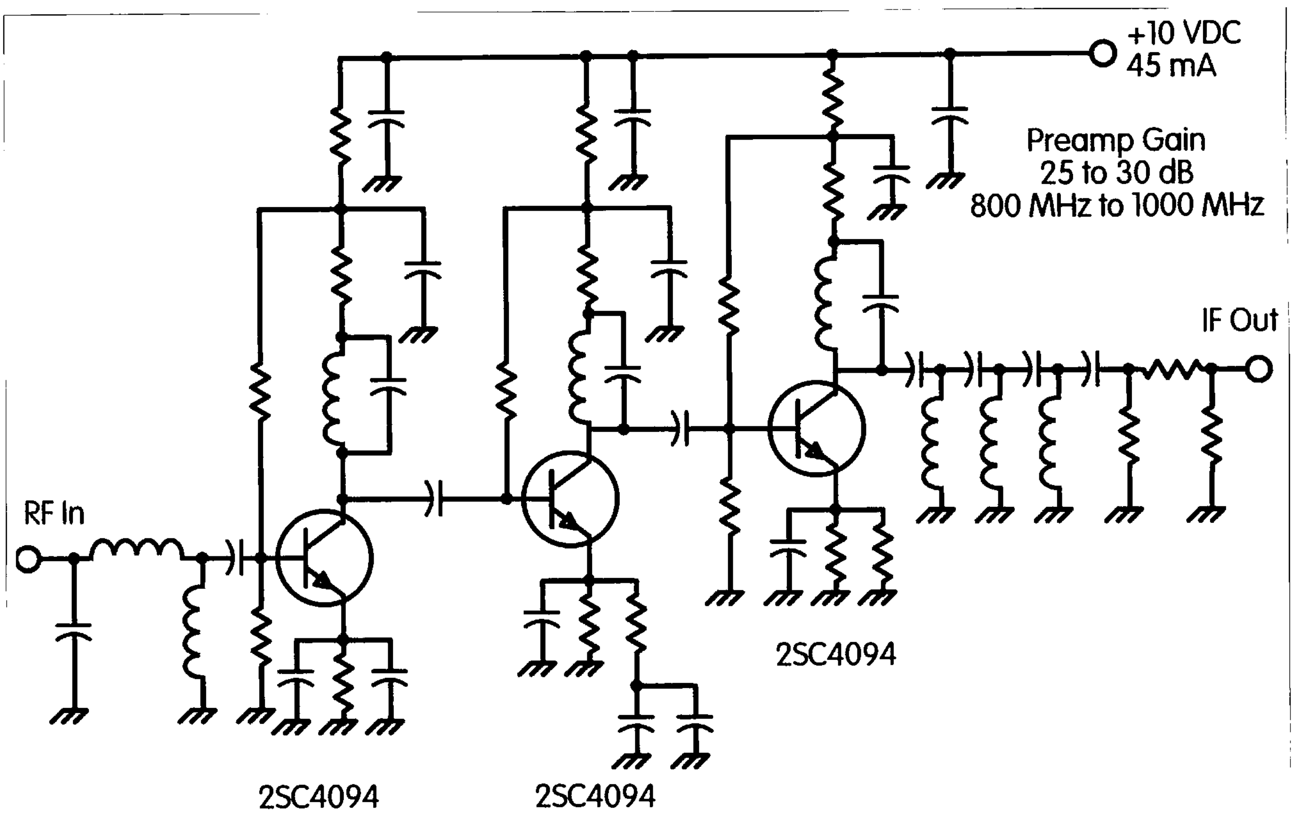

Fig. 2. Schematic diagram of the receive amplifier.

be excessive in these relays for 1296 MHz. The only way to prove this was to leave the theoretical environment and actually build the circuit as originally proposed.

The relays I selected were miniature metal-enclosed TO-5 relays manufactured by Teledyne. These relays are quite small and the exact size of a modest power transistor (TO- 5 metal-cased power transistor). I did not try the small 12 volt relays offered by Radio Shack (275-241) but I believe they should work in a similar fashion. The thing that is important about using any device at these frequencies is to make all leads as short as possible, especially the common ground leads. It is OK to make the RF amplifier leads longer.

I suggest mounting the relay upside down on a piece of copper circuit PC board blank. The entire copper foil of the PC board will serve as the ground shield and mount for all components. I used the position on the side wall for the coax connector in/out SMA connector to be exactly at the pin of the relay for the transfer contact. This gave minimum lead length to the relay by mounting it directly at the coax connector location.

What I have constructed is a reasonable layout that can be easily reproduced with the materials I will make available. However you are free to experiment and change the layout and application using the same components to suit your particular design requirements. In this case the old axiom applies: "If you change the recipe you might change the product." Give it a try if you like and watch for circuit layout and amplifier instabilities. Use similar PC board material of .062 double-sided copper to shield your circuit and connect the side plate with a seam of solder making a solid grounded enclosure. I soldered the side plates to each other and the bottom plate on the inside, connecting all copper foil surfaces together to form a shield.

Similarly a top cover is also cut out of PC board material to complete your RF-tight enclosure. See **Fig. 1** for the dimensions of the enclosure that I constructed. Dimensions do not have to be strictly adhered to; just follow something similar if you plan to use the IF amplifier boards that I will make available for this project.

The IF amplifiers that I used were surplus units removed from Qualcomm transceivers that we converted to 10 GHz operation. The specification on the receive RF amplifier is about 28 to 30 dB of gain and 2 dB noise figure making a very sensitive high gain RF front end. The transmit IF, or in our case RF amplifier, has less gain measuring 24 dB but it will provide a higher power RF output of nearly +10 dBm. While this is a peanut whistle (12 mW) it is still quite effective. External switching and a power amplifier will make this converter a formidable 1296 MHz transverter.

What I attempted to do is to provide you with the building blocks of circuitry to construct this converter. The thing that makes these amplifiers attractive is that they fit into this application like a glove. Their small size (1" x 3"), high gain and ready to place and play type of circuitry make them easy to use with +12 volt battery applications for home or portable rigs.

As I stated earlier, I will provide a mini kit of both the Rx and Tx PC boards with a 2000 MHz PC surface mount mixer and a short section of waveguide to construct an evanescent mode filter (see the end of this column for details). The only thing you will have to add is a local oscillator at 1152 MHz to complete the transceiver. That is if you also choose to use a 144 MHz transceiver for your IF system. The LO frequency would change if you change the IF frequency you use. If you used 432 MHz as the IF system frequency then the LO required would be 864 MHz.

Considering the 1152 there are several options on the LO, including a 96 MHz crystal oscillator followed by a times-three multiplier and double to 576 MHz, followed by a single doubler to 1152 MHz. An alternative would be to phase-lock up an old CATV front end on 1152 MHz for a very economical local oscillator. I have covered these for ATV projects and assume that with some modification they could adapt to this use as well. I used a different tack with a synthesizer that I had on hand.

This surplus synthesizer from Qualcomm is in small quantity and not easily available at present in the model that will generate 1152 MHz. We do have models that will lock up to 2304 MHz and, allowing for the onboard divide-by-two's reducing the LO to 1152 MHz, we might be able to tap off that line and use it in this application. I will have to try to find some time to try this modification and see if it is practical; more on this later. The actual synthesizer that I used is in the test bed area of my shack and I am in the process of documenting it. While it is an excellent choice, we do have a quantity of them and have not fully developed details for others to follow our conversion at this time. Also, this unit will prove to be costly because it comes equipped with a high quality 10 MHz TCXO on the PC board, this in addition to the 3036 synthesizer circuitry.

In the prototype conversion we were able to not only generate the required 1152 MHz for the converter's use at 1296 MHz transverter use, but also to use an additional oscillator port to drive a 3.7 to 4.2 satellite LNA by broadbanding its strip line circuitry to serve a harmonic amplifier. This LNA feeds a simple PC board antenna feed of triband proportions, making harmonics available for 2304 MHz, and 3456 MHz and higher harmonics available for calibration at other amateur frequencies. These frequencies are direct multiples of 1152 MHz.

I have tried both the CATV tuner's local oscillators and had some trouble increasing frequency higher to make it run at 1152 MHz. Normally the CATV tuner's upper frequency limits are near 1050 MHz and require modification to go higher. While the 3036-based synthesizer is much more complex, it is also the best local oscillator I have tried. However, it's somewhat expensive considering it comes with a 10 MHz high stability TCXO reference. Whatever local oscillator you select, this RF amplifier/mixer arrangement should prove quite easy to set up for a simple 1296 MHz converter.

The IF amplifiers provide gain over a 800 to 1700 MHz range. The receiver IF amplifier provides some 30 dB gain and exhibits a 2 dB noise figure, making a very good front end for a receiver converter. The transmit IF amplifier is also well suited for low power applications, or as a first driving amplifier. As it stands it provides +10 dB output power when driven from the mixer. Normally it has 25 dB gain but will only provide +10 maximum saturated out power in transmit. As both units run from a regulated +10 volts they are easy to use as they only require an input and output RF connection in addition to the +10 volts and ground.

In my application I mounted the amplifiers on the PC board with the receive amp facing forward or left to right, and the transmitting amp reversed with the receive amp. In this way I could use only one input and output RF connector and mount them on the side wall, which is about 3/4" high and constructed out of PC board material cut to length. All four sides are 3/4" high and soldered together. Another scrap of PC board material will serve at the top cover plate.

I mounted the two miniature TO-5 miniature relays as close to the coaxial connector for minimum lead length. I also soldered the relay coil with minimum lead length to ground. Place a rectifier diode across the relay coil for DC suppression. Position the other contacts as best you can to the input and output of the amplifier at their respective ends of the compartment. See **Fig. 1** for my particular layout. Exact replication of my layout is not necessary as long as your lead length is as minimum as you can make it. Remember that you are working at 1296 MHz and short leads are necessary.

The amplifiers both have input and output pads, making easy connection to their PC board circuitry. No adjustment or modification is necessary to their circuits; they can be used as they come. I soldered the PC board ground foil to the bottom circuit, making the amplifiers' PC board ground common and direct to the mounting bottom circuit board foil. I also mounted a third relay to switch the +10 volt DC line to either the Rx or Tx amplifier. Main DC input to the unit is 12 volts nominal and I used a 7810 voltage regulator mounted inside the case for the regulated DC supply.

This relay coil for the DC switch distribution is fed to an external key lead, making both the input and output coax (miniature TO-5 relays) switch when the DC control relay is also switched from this common key lead. In the nonkey condition DC power is supplied to the receive amplifier. When the key lead is energized the receive amp goes open and DC power is supplied to the transmitting amp and switching relay coils to energize them into operation.

This keying sequence can be changed to ground depending on your particular switching conditions. You don't have to follow my conditions; if yours are different make internal changes—don't modify your other equipment. If your keying conditions supply ground, tie the switching relay to +12 volts and run the open end to the switching lead. Bypass this lead with a feedthrough capacitor and ground to the transmit switch on this lead.

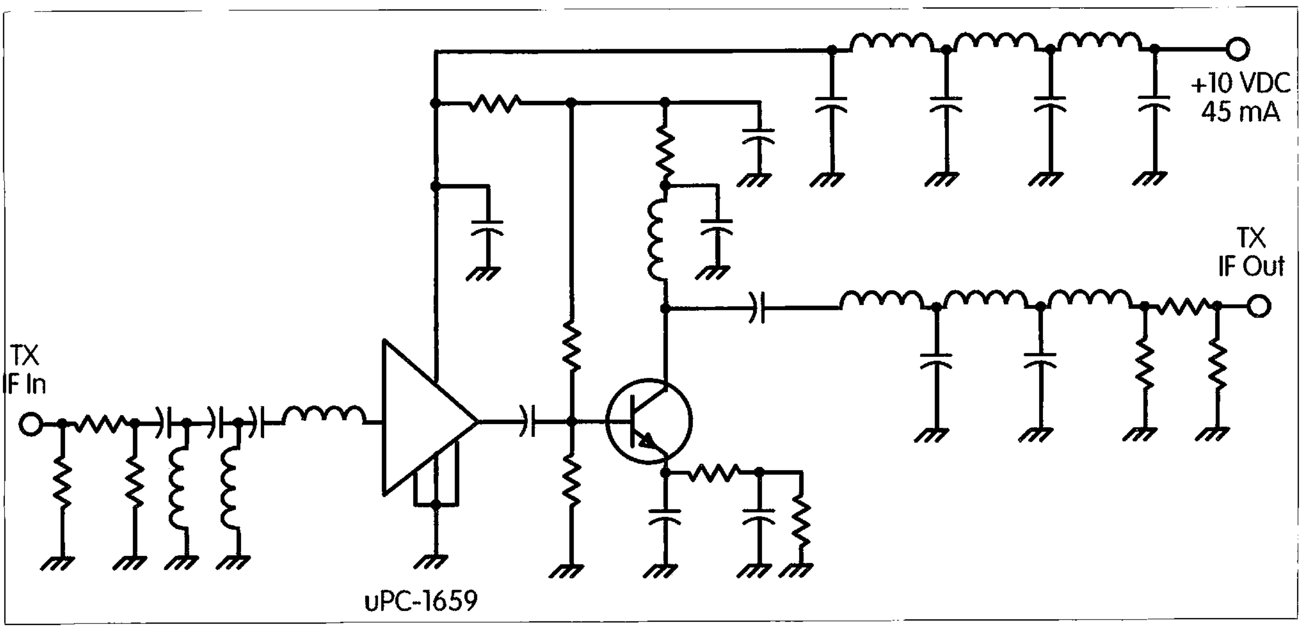

Fig. 3. Schematic diagram of the transmit amplifier.

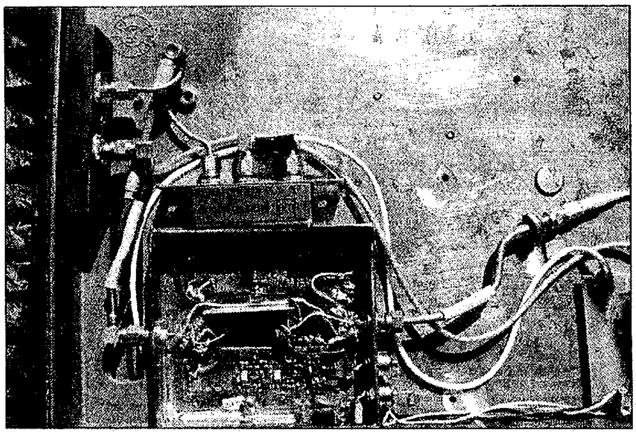

Photo A. *Completed converter unit, lower left corner of RF housing. Mixer mounted to upper part of converter case and waveguide filter (for 1296 MHz complete low level transverter system) to rear left of photo (requires LO at 1152 for complete package).*

Preventing trouble

The only important part of construction on this RF amplifier is to run leads to the input and output switching miniature relays in as short as possible a path to reduce loss and prevent unwanted stray effects like lead crosstalking, which is undesirable. What is lead crosstalking? Well, another term for this is the venerable alligator effect known as oscillation. The only difference between an oscillator and an amplifier is that a good functional amplifier will not oscillate. However, if you give this amplifier a chance by coupling between the input and output circuits it will take off and fly as a oscillator.

The best answer to preventing this effect is to bypass the power and switching leads with a feedthrough capacitor. Use small relays for coaxial switching, make ground connections as short as possible and use as direct wiring as possible. In some stubborn cases it might be necessary to construct some small case-high internal shields constructed out of small PC board scrap pieces and solder them to the common bottom ground surface to serve a grounded separator.

The cover plate can also be a source of trouble when it is attached. Let's suppose that you have just finished the amplifier/mixer unit and all tested out OK. It sounds just fine and you are satisfied with this amplifier and have tested switching and all is still OK. However, when you put the cover on the noise in your receiver increases or some other effect is in apparent, like the presence of "birdies in your receiver." What's up?

Well, chances are the container is acting like a short section of waveguide with an input and output connector serving as the connectors to a waveguide to coaxial transition, and we have resurfaced the old alligator trick again (when the cover is placed on the amplifier)! The solution is to remove the cover plate and place some black conductive foam and glue it to the inside of the cover plate. Other material can be used, even some iron particles from a smashed iron toroid core. What type of material to use? Well, it doesn't matter much as both the iron core particles and the black conductive foam present a very high impedance or resistance to RF from coupling between the input and output of the amplifier.

If you use broken ferrite core material, glue the small broken pieces to the underneath side of the cover plate. This also will help to place a lossy substance in the path of the oscillation, thereby reducing the case's susceptibility to aiding oscillation. If you can figure out where an amplifier is getting its coupling from input to output you can stop the oscillation using one of these tricks I just mentioned. It's not hard but it does take some small amount of time to make a very stable amplifier system when placed into metal containers. They all act like waveguide and couple so be careful and test each and every one you build to prevent unwanted oscillations.

Next month I will get into several dish antenna feeds that can be constructed, and cover several that were obtained from surplus.

Concerning the 800 to 1700 MHz amplifiers used in this month's project: I will make them available in a kit containing both the Rx and Tx amplifiers with a 2000 MHz surface-mount mixer and a short section of waveguide 17 to construct the evanescent mode filter, for $20 postpaid.

Well, that's it for this month. Next month I will cover microwave stripline tuning methods. 73 Chuck WB6IGP.

QRP

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

The days in January are always gray and cold in Ohio, so let's begin the new year with three construction projects. The projects are simple to build and they are useful, too. They're electronic keyers.

To make it easier for you to build these keyers, all the artwork has been laid out in Circad™ format. You can get a copy of Circad from any of the larger telcom suppliers. I know CompuServe has the latest version. AOL more than likely does as well. The demo version is usable, but some features are locked out. You can edit and print out these files with the demo version.

I will post all of the files for this column, except for Circad, in the HAMNET forum. Inside HAMNET, the files will be in the QRP library section. All three projects will be in the library, and one file will have all three projects together. So, you can download one, two or three files by themselves, or one file with all three projects. All files will be in ZIPPED format. You'll need PKUNZIP or another unzipping program to view the files.

Because I wanted as many hams as possible to give these keyers a try, subminiature parts and super-small PC boards were not used. Instead, the layouts are large enough so even a novice in home-brewing can have a very good chance of building a working project.

Two of the keyers were laid out by Jay Graswell WBØVNE. I worked on the last one, the DYI Plus keyer. One of the keyers is built on single-sided PC board; two require a double-sided PC board.

The Curtis keyer

The first keyer is a classic. Based on the Curtis keyer on a chip IC, the original project was done by Paul Page N1FB and Bob Shriner WAØUZO. The work appeared in the December 1983 issue of *QST* magazine.

Although many versions of the Curtis keyer have appeared, this version has most of the features, without making an overly complex project. Also, this version does not require a double-sided PC board.

Assembly is very basic. There's nothing really special to worry about. I would suggest, however, that you use a socket for the Curtis chip. The chip is a bit pricey.

As you can see in the overlay for the PC board, many of the controls for speed, sidetone volume and so on are mounted directly to the PC board. I would mount the speed control off from the board so you can easily change its setting. Aside from the speed control, leave the others as shown.

Your local Radio Shack™ should be able to supply you with almost everything you will need. Radio Shack also carries a nice selection of project boxes to put the keyer in. The PC board is a bit large to fit inside some of the QRP rigs out today. This keyer would be a excellent choice for a benchtop unit.

Radio Shack won't have the trimmers nor the Curtis keyer chip. You can get the trimmers and the Curtis keyer chip from Mouser Electronics, 1-800-992-9943. Point your browser at their World Wide Web address at www.mouser.com.

You can also obtain the Curtis chip from Jade Products at 1-800-523-3776. Their web site is: www.hampstead.k12.nh.us/~djade/index.html. Jade Products also sells a Curtis keyer kit at $46.20 PP. It is *not* the same one presented here, however.

Right now, I'm not sure PC boards will be available. It's possible I may be able to talk FAR Circuits into making some of the single-sided boards. I will let you know if any of the boards will be made.

The DYI Plus keyer

This is an old favorite of mine. This time around, I've changed the layout and put the circuit on a double-sided PC board. This makes the keyer much smaller than the original version on its single-sided PC board. And, there was enough room to add an extra transistor and a reed relay. This relay allows the keyer to key transmitters using emitter keying. If your QRP transmitter requires the emitter of the oscillator transistor to be pulled to ground, a transistor switch may not do the job adequately. The results are usually a bag of unwanted chirps and tweets.

Because the CMOS chips will operate on a wide range of power supplies, I did not use any inline regulators. I would steal power from a regulated source from your rig. The CMOS will be happy with anything between 5 and 16 volts. Current demand for either of the keyers in this trio is just about zip. Only the relay demands a stiff amount of current.

The relay I used in the DYI Plus is an off-the-wall item at Radio Shack. It comes in two different voltages: 5 volts and 12 volts. If you run your DYI Plus from a 12 volt source, guess what relay you should use? The relays have the following Radio Shack numbers: for 5 volts, 275-232; for 12 volts, 275-233. Mouser electronics also sells these relays.

When I did this version of the keyer, I added a header to the circuit board on .100 centers. My idea is to use those cute shorting jumpers and a header to select between relay keying and solid-state keying. There is no reason why you can't use a clipped resistor lead instead of the shorting jumpers. And, there is enough current from the 4027 to drive both transistors. This way, you could have two outputs, although why is beyond me.

Speaking of headers, I also laid out the board to accept .100" headers for the speed pot and all the I/Os. I just hate seeing a project with a zillion wires soldered in place. The use of the plug-in headers makes for a much cleaner installation. If you can train yourself to use a standard header, you could switch out one keyer project for another.

G3BIK's keyer

The last keyer in our trio is by G3BIK, and comes from the Oct. 1994 issue of *Radio Communication*.

The circuit is very similar to that of the DYI keyer. The difference lies mainly in the choice of ICs used. Instead of the 4011, a 4093 is used. A 4013 replaces the 4027 used in the DYI keyer. Also, this keyer has an onboard 1 kHz keying monitor. It will drive one of those piezo units. I'm not sure I would like to use one of those for sidetone monitoring!

Note that this keyer is laid out so it is very narrow and only one inch wide. It would fit along the backside of just about any QRP rig. The relay TX output will ensure total keying compatibility.

Assembly

No rocket science stuff here. If you have assembled a few kits now and then, you should be able to get all three of these to work.

The only cautions are to handle the CMOS chips carefully; they're subject to damage caused by static. The ICs must also be installed correctly. Reverse one and it's almost a sure bet it's toast. I'd use IC sockets, especially on the double-sided PC boards. The prototypes I made had plated through holes. If you decide to make your own double-sided boards, be sure to solder the connections on both sides of the board.

I'd use a 9 volt battery to test out these keyers. There's no need for large high-capacity gelled batteries. In fact, just in case you have something out of whack, you'll do little damage with the 9 volt battery. On the other hand, you can easily burn off copper traces with a gel cell.

I've built the DYI Plus keyer and the Curtis keyer board. They work just fine. I have not assembled the G3BIK keyer.

Again, I'll have all the files uploaded to the QRP section on CompuServe. And, of course, the QRP section is hiding inside HAMNET. If I come up with any changes to either the boards or the schematics, I'll have the updates in those libraries.

If there is enough interest, perhaps a small run of double-sided PC boards with plated through holes will be made for the DYI Plus keyer.

Next month I'll have some more odds and ends for various circuits you can use for your latest QRP projects.

Ham Radio Fun

Communications Simplified, Part 13

Peter A. Stark K2OAW
P.O. Box 209
Mt. Kisco NY 10549

It's time to look at the transmission lines that connect the antenna to a receiver or transmitter.

Characteristic impedance

Let's review what we said about characteristic impedance earlier in this series. Think for a moment about how an ohmmeter works. Inside every ohmmeter is a small battery. When you connect the ohmmeter across a resistor, the meter connects that battery across the resistor. Current starts to flow through the resistor, the meter measures how much current there is, and computes the resistance from Ohm's law:

$$\text{resistance} = \frac{\text{voltage across resistor}}{\text{current through it}}$$

Now, imagine that you have an infinitely long length of some cable, such as the flat twin-lead cable used for TV antennas, and you connect the ohmmeter between the two wires at your end. What will you measure?

Connecting the ohmmeter to the end of your cable connects its battery across the two wires. The ohmmeter, of course, doesn't know whether there is an inch, a foot, or a mile of wire there, so it sends some current out its test leads, hoping eventually to reach a resistor at the end. Normally, the current would reach a resistor after going through just a few feet of wire, and settle down to whatever current Ohm's law wants. In this case, however, that test current just keeps going forever (at almost the speed of light), searching for a resistor that isn't there. The ohmmeter doesn't know that this test current never reached a resistor; it happily measures the current and voltage, and displays a value of resistance anyway.

The amount of current that flows depends on the kind of cable. Actually, its resistance has fairly little to do with it; it's the capacitance between the two wires and the inductance of the wires that mainly determine how much current flows down the cable. The resistance the meter measures therefore depends on the type of cable; we call it Z_0, or the *characteristic impedance* of the cable.

Different cables have different characteristic impedances—the TV twin-lead is 300 ohms, the coaxial cable used for TV antennas is 75 ohms, while the coax generally used for transmitting antennas is 50 ohms. And the twisted-pair cable generally used for audio and telephone circuits would measure 600 ohms.

Reflections

Now look at **Fig. 1.** Here we see a simple circuit, consisting of a 10-volt battery, a switch, and a 10-ohm resistor, all connected in series. Right now, the switch is shown open, and so there is no current. Once we close the switch, current starts to flow. The value is given by Ohm's law as V = I/R; this works out to 10 volts/10 ohms, or 1 ampere.

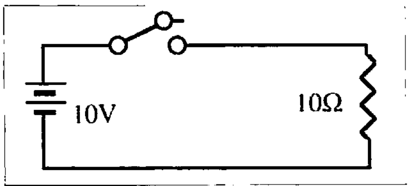

Fig. 1. A simple series circuit.

But let's complicate the issue a bit by making the wires between the switch and the resistor 186,000 miles long. To simplify things a bit, let's assume that the wire has no resistance, but it does have a characteristic impedance Z_0 of perhaps 100 ohms. What is the current just after we close the switch?

Since it takes light one second to travel the distance from the resistor to the switch and battery, even if the battery had a high-power telescope so it could "see" the resistor at the far end, it could still not know precisely what is at the end of the wire at the instant the switch closes—it could only see what was there one second earlier. So, as before, the current it sends out depends not on the resistor, but on the characteristic impedance of the line. The current is therefore:

$$I = \frac{10 \text{ volts}}{100 \text{ ohms}} = 0.1 \text{ ampere}$$

So, if we had a voltmeter and ammeter connected at the switch, we could see 10 volts and 0.1 ampere entering the line as soon as the switch closes. A half-second later, that voltage and current reach the middle of the line; one second later they finally reach the resistor.

The problem is that 10 volts and 0.1 ampere are all wrong for a 10-ohm resistor. By Ohm's law, if there is 10 volts, there should be 1 ampere; if there is only 0.1 ampere, then there should be only 1 volt. The resistor therefore looks at the voltage and current reaching it, and says "No, no, no—something is wrong—there is either too little current, or too much voltage—or perhaps both!"

The resistor therefore short circuits some of the applied voltage to bring it closer in line with what should be there, considering the amount of current. This temporary short circuit causes an additional current to flow through the resistor as well.

This situation, however, leads to a contradiction. At the resistor, the voltage is now lower than 10 volts while the current is slightly higher than the original 0.1 ampere. However, a short distance back from the resistor the line voltage and current are still 10 volts and 0.1 amperes. But this can't be! In a parallel circuit, the voltage must be the same everywhere, while in a series circuit the current should be the same as well. And so the drop in voltage and increase of current must start to travel back along the line, eventually making the voltage and current the same everywhere.

One way to look at this is to think of an outgoing signal (10 volts and 0.1 amperes) traveling from the battery to the resistor, and a second, returning signal, traveling back from the resistor toward the battery. The returning signal adds to (or subtracts from) the outgoing signal, changing the total voltage and current along the wire. In technical terms, we say that the returning signal is a *reflection* —part of the outgoing voltage and current have been reflected from the load, and travel back along the line.

The reflection will eventually reach the battery, which will look at the lower voltage, and do everything it can to boost it back to the required 10 volts. In the process, it will send out a burst of more voltage and current (but still the wrong values). These will go back to the resistor, cause yet another reflection, and so on. Eventually, the voltage and current will stabilize at the 10 volts and 1 ampere that DC circuit theory says we should have.

We can calculate how much voltage is reflected from the *reflection coefficient*, represented by the capital Greek letter gamma:

$$\Gamma = \frac{Z_L - Z_0}{Z_L + Z_0}$$

where Z_L is the value of the load resistor (100 ohms in this case), while Z_0 is the characteristic impedance (which is 10 ohms in our example). So in this case, the reflection coefficient is:

$$\Gamma = \frac{Z_L - Z_0}{Z_L + Z_0} =$$

$$\frac{100 - 10}{100 + 10} = \frac{90}{110} = 0.818$$

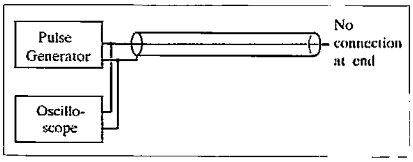

Fig. 2. Time-domain reflectometry.

What this means is that 81.8% (a fraction of 0.818, or 8.18 volts) of the outgoing 10 volts will reflect off the 1-ohm resistor. The voltage across the resistor will then be 10 - 8.18 = 1.82 volts. Knowing how much voltage will actually reflect is nice, of course, but it's more interesting to look at three special cases.

Case 1: There is no load resistor at the end of the cable at all—the output is open. In this case, Z_L is infinity, and the equation becomes:

$$\Gamma = \frac{\infty - Z_0}{\infty + Z_0} = \frac{\infty - 10}{\infty + 10} = \frac{\infty}{\infty} = +1$$

That's because the infinity on the top and bottom are so big that we might as well ignore the Z_0. So, with the output open, the reflection coefficient is +1, and 100% of the outgoing signal is reflected.

Case 2: If, on the other hand, the end of the cable is shorted, then Z_L is zero, and the equation becomes:

$$\Gamma = \frac{0 - Z_0}{0 + Z_0} = \frac{0 - 10}{0 + 10} = \frac{-10}{+10} = -1$$

In this case, the reflection coefficient is -1, and so -100% of the outgoing voltage is reflected. That is, it is all reflected, but the polarity changes (that's what the minus sign means). That makes sense, since the voltage at a short circuit must be zero; the only way to get this is if the outgoing voltage and the returning voltage exactly cancel each other out.

Case 3: Suppose, on the other hand, that the load resistance Z_L is exactly equal to Z_0? In that case, the numerator of the equation becomes $Z_0 - Z_0$, which is zero. The reflection coefficient is therefore zero, and nothing is reflected at all.

So we see that the only way to get no reflection is to load the end of the line with a resistance exactly equal to the characteristic impedance of the line itself.

Let's see how reflections in cables can cause problems.

Reflections in digital circuits

Fig. 2 shows a simple test circuit which we can rig up in the lab. At the left we have a pulse generator; the pulse generator acts sort of like a battery and switch, except that it closes the switch only for a very short time (sometimes as short as just a few billionths of a second). In other words, it connects a voltage to the line for a tiny instant, and then immediately disconnects it again. The pulse generator feeds a length of transmission line (we use 100 feet of RG-58 coax cable in our lab experiment), whose far end is shown open. A fast oscilloscope is connected across the pulse generator to show us the signal.

Fig. 3 shows the result. The fairly sharp pulse at the left is the signal coming out of the pulse generator. It appears as a narrow pulse, on for just a very short time. The slightly smaller pulse at the right is what comes back from the end of the line—this is the reflection. It is slightly smaller, because there is about a 10% loss of voltage in going down the cable and back (this is, after all, a practical cable, not a theoretical, loss-free one). Note also that the returning pulse is slightly wider and not nearly as nice and square. This is caused by the various parts of the pulse traveling down the cable at slightly different speeds, which results in the pulse spreading slightly.

From this picture, we could calculate the signal loss in the cable; much more interesting, though, is to calculate how fast the signal travels. In this picture, the scope sweep was set to 0.05 microseconds per division; since the spacing between the two pulses is about six divisions, the delay between the outgoing and returning pulses is about 0.3 microseconds. In that time, the pulse traveled 200 feet (100 feet from the generator to the end, and another 100 feet to return). The signal velocity is therefore:

$$\text{velocity} = \frac{\text{distance}}{\text{time}} = \frac{200 \text{ feet}}{0.3\ \mu\text{sec}} =$$

$$6.67 \times 10^8 \text{ feet/sec}$$

Since there are 5,280 feet in a mile, this works out to about 126,000 miles per second. Note that this is slower than the speed of light, which is usually given as 186,000 miles per second; this latter figure is only true for light in a vacuum anyway, not for light in air, glass, or other materials.

In our electrical case, the speed of the signal in the cable is only about 67% of the speed of light; we call this number the *velocity factor* of the cable, and usually write it as 0.67 rather than 67%. (Remember that our measurement is only an approximation; the actual published velocity factor for RG-58 cable is slightly less, but the delay time is hard for us to read from the scope, and so 0.67 is about as close as we're going to get.)

The velocity factor is thus:

$$\text{velocity factor} = \frac{\text{actual speed}}{\text{speed of light}}$$

Now imagine that the pulse in **Fig. 3** is just one of many pulses being sent in a cable, perhaps as part of a computer local area network. If the end of the cable is open, then the pulses reflected from the end will get mixed in with the outgoing pulses and cause major errors in the system. So reflections can be a big problem.

Fig. 3 dealt with a line whose far end was open. If the far end had been shorted, there would still be a reflection, but the reflected signal would be negative instead of positive.

From our previous discussion, we can now see that the only way to prevent reflections is to make sure that the end of the cable is properly terminated—we must place a resistor at the end of the line, and make sure that its resistance is equal to the characteristic impedance of the line. If the resistance is slightly off, there will be a reflection, but it might not be large enough to matter. In general, a resistance larger than the characteristic impedance will provide a positive reflection; a resistance smaller than the characteristic impedance will provide a negative reflection. Thus the cables in local area networks are always connected to a load resistor at the end; sometimes the resistor will be inside the computer interface card, other times it may be mounted externally, but it will always be somewhere. And since the signals in these cables can travel in either direction, there will be a termination resistor at each end of every cable.

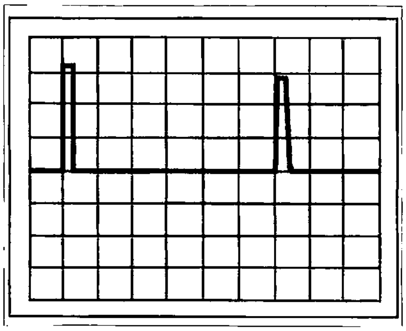

Fig. 3 Reflection from an open circuit.

Incidentally, putting a proper load resistor at the end of the cable is not enough—*how* you connect it is important too. If that resistor is right at the end of the cable, with short leads, all is fine. But **Fig. 4** shows what happens if that resistor is connected with foot-long clip-leads. There is still a small reflection; in fact, there are now *two* small reflections. At point A is a small positive reflection, caused by the clip-leads. The two clip-leads make a small transmission line, but its characteristic impedance is higher than that of the coax cable. So we get a positive reflection at this point. A foot later, the termination resistor has a lower resistance than the clip-lead impedance, and so we get a small negative reflection at point B. This points out that this type of test, called *time-domain reflectometry* (or TDR) because it measures the reflections and the time they occur, lets us analyze the locations of shorts and opens, as well as the locations of bad connections. Commercial TDR instruments are thus very useful for finding problems in buried or hidden cables.

Reflections in analog circuits

Analog signals can be reflected from the ends of cables just as digital ones can. For example, consider the antenna lead from a TV antenna to the TV set. To prevent reflections, the characteristic impedance of the cable usually matches the impedance of the antenna, and the impedance of the TV set's antenna input. Since there are two kinds of common antenna leads in use—the flat "twin-lead" cable which has a Z_0 of 300 ohms, and TV coax with a Z_0 of 75 ohms—many TV sets have two separate inputs as well. TV antennas usually have a 300-ohm connection, but we often use a 75- to 300-ohm transformer to match it to coax cable. (There's a second reason, too—the 300-ohm twin-lead is a balanced lead, whereas the coax is unbalanced, so slightly different connections are needed.)

Why the careful impedance matching? Because reflections can cause delays. If some of a received TV signal went directly to the TV set, while a small portion of it was reflected from the set back to the antenna, and then reflected a second time from the antenna back to the set, the TV set would get a weak signal shortly after the main, strong one. This would cause a ghost image to appear to the right of the main image. (If you get ghosts in your TV image, don't immediately blame the antenna installation. Ghosts are also often caused by reflections from nearby buildings, hills, or other large objects.)

But there is a second way to look at reflections of analog signals. Let's suppose that the signal entering the coax line in **Fig. 5** is not a pulse, but a sine wave. The reflection will then also be a sine wave, rather than a pulse. Depending on the length of the line, that reflection could arrive at the beginning of the line at various times. So let's examine a few special cases.

Case 1: Suppose that the line is exactly one-quarter of a wavelength long, and its far end is open-circuited. We earlier defined a wavelength as the distance a signal travels in the time of one cycle. The equation for the wavelength lambda was:

$$\lambda = \frac{\text{velocity}}{\text{frequency}}$$

For the velocity, of course, we now have to take the velocity in the cable, and we have already learned that this velocity is smaller than the speed of light in a vacuum; it is the speed of light times the velocity factor for the particular cable.

Let's put some numbers on this. Suppose we use an RG-58 cable with a velocity factor of about 0.65, and a

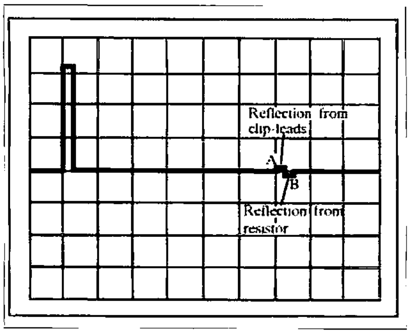

Fig. 4. Reflection from a bad load.

frequency of 1.6 MHz. One wavelength is then:

$$\lambda = \frac{186{,}000 \text{ miles per second x } 0.65}{1{,}600{,}000\,\text{Hz}}$$

$$= 0.0756 \text{ mile}$$

which is about 399 feet. A quarter-wavelength is then about 100 feet.

So let's take 100 feet of RG-58 cable, leave the far end open-circuited, and send a 1.6 MHz signal into it. The signal will take exactly one quarter of a cycle to travel down to the end. Since the end is open, the reflection coefficient Γ is +1, and so the signal is completely reflected. It now takes a quarter of a cycle to travel back to the beginning of the line, arriving exactly one-half of a cycle after it started. Assuming a low-loss line, the signal coming back will be almost exactly the same size as the outgoing signal.

The only problem is that the returning signal is now exactly one-half of a cycle behind the outgoing signal. In other words, the positive half-cycle of the sine wave arrives just as the signal generator is producing the negative half-cycle. And so the positive and negative half-cycles exactly cancel, producing 0 volts at the input into the line. The oscilloscope will see nothing.

Let's think about this for a moment. The signal generator in **Fig. 5** is generating a voltage (we didn't specify how big) but the actual voltage measured by the scope at the input into the line is 0 volts. How can that be? The only possible explanation is that the transmission line behaves like a short circuit. There is current, but no voltage.

We can summarize this as follows: *A quarter-wavelength transmission line which is open-circuited at the far end behaves like a short circuit at its input.* It may be a bit hard to believe, but it is true.

One more thing: The generator, thinking it is feeding a short circuit, is outputting more than its normal current, trying to overcome that short. So the input to the line is a point of zero voltage, but higher than normal current.

Case 2: Let's now take a similar case, but instead of leaving the far end of the line open-circuited, let's short it and see what happens as the positive half-cycle part of a sine wave leaves the signal generator.

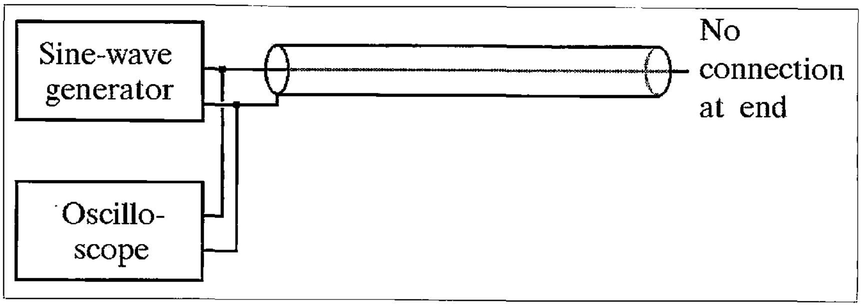

Fig. 5. Reflection of a sine wave.

The signal takes a quarter of a cycle to reach the short. Because the reflection coefficient Γ at a short is equal to -1, the positive half of the sine wave is completely reflected, but the minus sign means that it becomes negative rather than remaining positive. This signal now takes another quarter of a cycle to arrive back at the signal generator, arriving exactly a half of a cycle after it left.

Let's stand back and think about this for a moment. The positive half of a cycle left the generator, was inverted at the reflection, and returns just as the generator is outputting the following negative half of the cycle. The generator is now trying to output a negative voltage, but there is already a negative voltage on the line. So the generator doesn't really have to do anything to make the voltage negative. Hence it does not output any current. How can that be? The only possible explanation is that the transmission line behaves like an open circuit. There is a voltage, but no current.

We can summarize this as follows: *A quarter-wavelength transmission line which is short-circuited at the far end behaves like an open circuit at its input.* This, too, may be a bit hard to believe, but it is true. Given the right test equipment, you can prove it for yourself.

We can extend this idea to other lengths of cables. For example, the cable in **Fig. 6** is 3/4-wavelength long. What do we see if we look into the input?

Let's imagine that the line is split into the three parts labeled **A**, **B**, and **C** in **Fig. 6**, each part a quarter of a wavelength. Since the right end of part **C** is open, the left end of it looks like a short. Part **B** is therefore shorted at the right, so its left end looks open. Finally, part **A** sees an open at its right end, so its left end looks like a short. So a 3/4-wavelength line which is open at the far end looks like a short at its input.

We can extend this reasoning to any line whose length is some multiple of a quarter-wavelength, and which is either shorted or open at its end. But what about other lines?

More complicated cases

In most cases, transmission lines will not be an exact multiple of a quarter-wavelength, and they will not have an exact short or open at their end. What then?

The mathematical analysis of such cases is fairly difficult, and most professionals will use a special kind of graph called a Smith Chart to figure out what happens. But even without the Smith Chart, we can still get a general idea of what is going on. So let's consider the case in **Fig. 7**, where we see a transmitter feeding a 75-ohm load (most likely an antenna) through a 50-ohm transmission line that is 1.68 wavelengths long.

Because the load resistance is not equal to the line's characteristic impedance, there will be a reflection. The reflection coefficient is:

$$\Gamma = \frac{Z_L - Z_0}{Z_L + Z_0} = \frac{75 - 50}{75 + 50} = \frac{25}{125} = 0.2$$

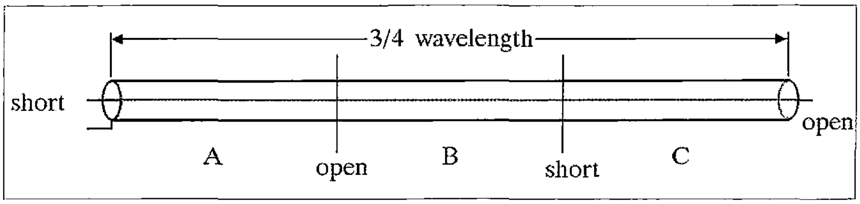

Fig. 6. A 3/4-wavelength line.

73 is accepting manuscripts for the June 1997 Field Day Issue.

If you had a good time at that last Field Day, or have ideas about how to make the next one a big success, submit your manuscript on a 3-1/2 inch disk, along with a print out and photos, by the end of February, to: Joyce Sawtelle, 73 Amateur Radio Today, 70 Route 202 North, Peterborough NH 03458.

Time's almost up, so if that manuscript file is still hiding the depths of your computer waiting for the spell-checker, drag it out of there and put it in the mail.

The best way for you to fill this magazine with what you most want to see is to fill it yourself.

so 20% of the outgoing voltage is reflected back to the transmitter. Let's assume that the transmitter is putting out 10 volts of RF; the reflected voltage is then 2 volts. This is obviously not good, because the load is not getting as much power as it should.

As the reflected signal goes back to the transmitter, there will be points along the cable where the reflected voltage will add to the outgoing voltage, giving us more than 10 volts. This voltage is called V_{max}, and is equal to:

$$V_{max} = V_{forward} + V_{reflected}$$

In our example, this voltage is 10 + 2 = 12 volts.

At the same time, there will be other places along the line where the two voltages are opposite, and so they subtract to give:

$$V_{min} = V_{forward} + V_{reflected}$$

In our example, this voltage is 10 - 2 = 8 volts.

Ideally, if the load was perfectly matched to the line, there would be no reflected voltage, and so V_{max} and V_{min} would be equal—the voltage would be the same 10 volts everywhere, and there would be no maximum or minimum. But that seldom happens exactly.

The presence of maxima and minima means that we can take measurements along the line, and find these points of maximum and minimum. This is not particularly practical with coax cable, but it can be done with open-wire balanced lines, where you can easily get to the wires to take voltage readings between them It is also sometimes done with microwaves: microwave signals (i.e., signals with a very high frequency on the order of gigahertz) are usually carried in waveguides (more on these later). It's possible to cut a slot into a waveguide and insert a small probe to take voltage readings inside it. This can be used to measure the VSWR, but it can also be used to find the frequency. Because the distance from a maximum to a minimum point is a quarter-wavelength (and the distance between two minima is therefore a half-wavelength), this can be used to measure the wavelength of a signal. If you know the speed of the signal in the waveguide, you can then calculate the frequency.

We say that these minima and maxima indicate the presence of *standing waves* along the line, and then define a *standing wave ratio* (also called a *voltage standing wave ratio* because we measure the voltage), abbreviated as SWR or VSWR:

$$VSWR = \frac{V_{max}}{V_{min}} = \frac{V_{forward} + V_{reflected}}{V_{forward} - V_{reflected}}$$

In our case, this is 12/8 or 1.5.

In the best case, if V_{max} and V_{min} were equal, the VSWR would be 1; many people read this as "1 to 1" or 1:1.

In the worst case, when *everything* is reflected, $V_{forward} - V_{reflected} = 0$ and the denominator is zero, so the VSWR is infinite. So measuring the VSWR is a common way of checking whether an antenna is well matched to the transmitter and its feedline. (It is not a perfect measure, because a resistor load equal to the transmission line's characteristic impedance would produce no reflections, yet obviously radiate no signal into the air!)

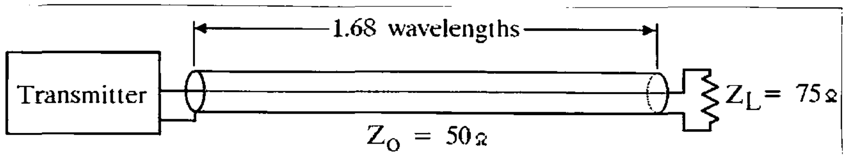

Fig. 7. A more typical example.

73 wants your feedback... we've been improving *73* for the past months with more articles, easier reading type, etc. And honestly, we *need* your feedback (in detail) if you have any critique either for or against the subtle changes that we've made. We know we can't please everyone every time, but if you tell us what you want *73* to be, we'll at least try to head in the direction for further "improvements" that might be most appealing to you. Thanks.

Build a Well-Regulated Power Adapter

Add some stability to your plug-in wall transformer.

James Tarchinski N8PTG
3135 Primrose Drive
Rochester Hills MI 48307

As you flip through the pages of *73*, or any other source of electronics circuit information, you'll find that many of the circuits either incorporate or need to be powered externally by a positive 5-volt DC power supply. Five-volt supplies are by far the most common supply value used for today's electronics. Knowing this, one would assume that there must be dozens of 5-volt regulated DC power adapters on the market, right?

Wrong. The free enterprise system has missed the mark on this one—regulated 5-volt adapters are nearly nonexistent, so electronics hobbyists often end up incorporating supplies into their project designs. In fact, they tend to design and build these supplies over, and over, and over again. But you don't have to keep repeating yourself—there is a better way.

Wall adapters can provide a convenient way of powering your electronics projects; you just need to modify them so they have the correct output characteristics for just about any regulated voltage that you will ever need! Because everyone has a different application with different design criteria, however, we do not go through one particular design. Rather we will discuss how to modify wall adapters in general, concentrating particularly on how to modify an adapter electrically without reworking the basic packaging of the unit's electronics.

A bit of history

The consumer electronics industry as we know it today would not exist if it were not for "industry standards." Industry standards are essentially gentlemen's agreements among companies stating that they will all produce products that utilize a standard format for something. This type of arrangement allows companies to save money by jointly developing a new technology, but yet they can each make money by selling their own unique products.

For example, before any company sold a compact disc (CD) player, all the major audio manufacturers of the world agreed on the specifications for the disc format. From the

#	Labeled Voltage	True Voltage	% Error
1	+5	5.10	2.0%
2	+5	9.65	93%
3	+6	7.94	32%
4	+6	8.42	40%
5	+9	10.34	15%
6	+12	12.38	3.2%

Table 1. *"Don't believe everything you read." The true output voltage can differ from the rated voltage in a random sampling of DC adapters. Adapter #2 was the worst unit tested, with an output nearly double the voltage listed on its case.*

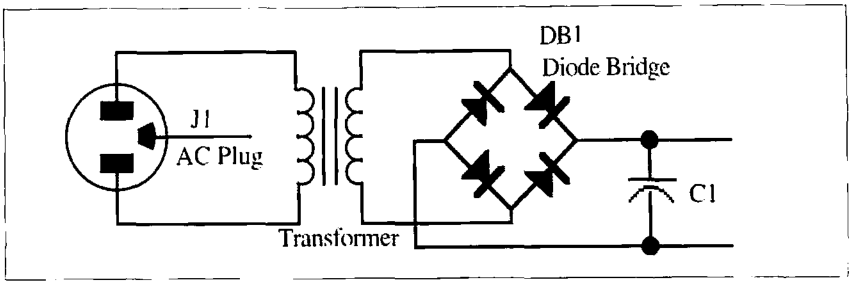

Fig. 1. The basic type of power adapter. The lack of any semiconductor regulator devices helps to keep the adapter's cost down, but it also keeps the unit's usefulness down.

consumer's point of view the end result was that you can now listen to the same CD on equipment made by RCA, Sony, Tandy, or any other of several dozen different manufacturers. When you bought your equipment you didn't have to choose between a RCA player and disc format or a Sony player and disc format. We were not so lucky when it came to other areas of home electronics.

Of course, VCRs come to mind. When these devices first hit the market they came in two flavors: VHS and Beta. After years of battling, VHS finally won and the Beta format went the way of eight-track players. Those people who backed the Beta format were the big losers, as they ended up with machines that no longer have tapes available for them.

Another area that still suffers from a serious lack of standardization is that of the AC-to-DC power supplies that are used with consumer electronics equipment. These supplies can be found in any voltage that is a multiple of 1.5 volts, from 1.5 to 13.5 volts. Furthermore, there are numerous different styles and even sizes of plugs currently used with these devices. And finally, there are plugs on the market that are wired with either polarity—with the tip being positive and the ring being negative, or vice versa.

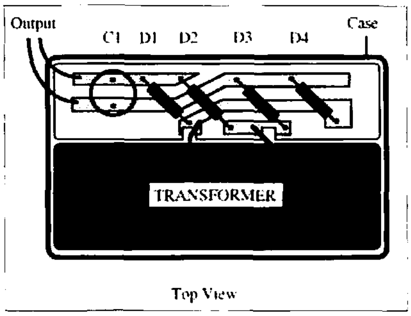

Fig. 2. In spite of the limited number of components stuffed into the enclosure of an off-the-shelf power adapter, there is not generally much space available for expansion.

Another problem with plug-in AC-to-DC supplies is that they don't always output the voltage indicated on their cases! To illustrate this point, I surveyed six different supplies, each made by a different manufacturer. While in the best case the actual output voltage was within 2% of the rated voltage, the worst-case supply was off by a whopping 93% (see **Table 1**).

There are a number of reasons why the actual output voltages of supplies are so different from their specified values, but by far the most common is cost. In order to make the supply as cheap as possible, most do not have solid-state regulators incorporated in their design, so their output varies directly with the line voltage supplied by the power company. Also as a cost-cutting measure, very liberal tolerances are used in the manufacture of these devices, and there is generally a lot of unit-to-unit variability in performance.

The load being driven by the supply is also an important factor in determining its net output voltage. For the data presented in **Table 1**, all the supplies were tested in their open-circuit configuration. But when an adapter is supplying its rated current the output voltage will almost always drop below its open-circuit voltage. Other than by testing the adapter under different loading conditions, there is no way to predict how far the output voltage will fall.

The variability of a power adapter's output is the main obstacle to using it to run circuits containing integrated circuits. One of the simplest ways of overcoming this obstacle is to install a voltage regulator on the DC output side of the adapter.

The electrical design

Fig. 1 is the schematic for a very simple AC-to-DC converter, while **Fig. 2** is the associated board layout. As you can see, the circuit contains nothing more than a standard full-wave diode bridge rectifier and a single filter capacitor. While this design is cheap, the voltage output is not very stable and therefore probably not suitable for any of your projects that use integrated circuits.

The circuit can be easily modified to incorporate a regulator, however. It is the job of the regulator to stabilize the adapter's DC voltage over a wide range of input voltages and output currents.

One of the most commonly used types of voltage regulators is the 78xx series. Low cost and the availability of several regulation voltages are among the reasons for the popularity of this line. **Table 2** is a list of regulators included in the 78xx series.

Fig. 3 is the pinout of a 78xx regulator in a TO-220 case. When viewed from the front, the leftmost pin (pin 1) is the input voltage line, which must be supplied with an input voltage that is at least 3 volts greater than the device's specified output voltage. Pin 2 of the device

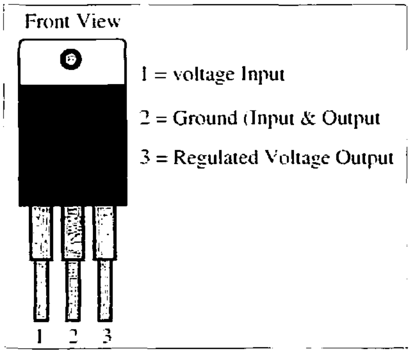

Fig. 3. Pinout of the 78xx series of voltage regulators.

is the common (ground) line shared between the input and output pins. Finally, pin 3 is the output line, which distributes the regulated voltage.

It is a simple matter to incorporate a 78xx series regulator into the basic power adapter design just described, creating a wall adapter with a well-regulated output. **Fig. 4** shows how this is done.

The power adapter you start with will need to have an output voltage, before modification, of about 3 to 5 volts higher than the regulated voltage you'd like to achieve. This requirement is imposed by the 78-series regulators, which need to see the higher voltage in order to regulate properly. If you refer again to **Table 1** you'll see that this should not be a problem, as most adapters output a higher voltage than specified on their labels.

Besides the regulator itself, only a few additional capacitors are needed to filter both the input and output voltages. The large caps are used to "smooth out" the voltage produced by the full-wave rectifier, storing energy for when the input AC signal changes direction. The smaller caps are used to filter out high-frequency noise, since they tend to look like short to ground to high-frequency signals.

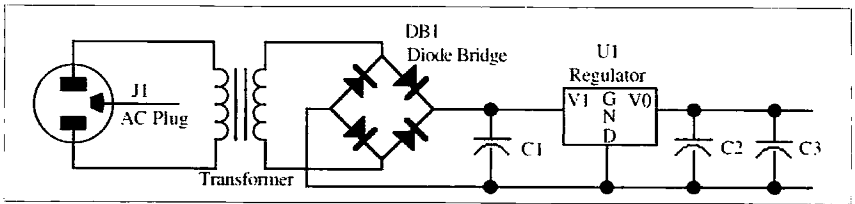

Fig. 4. The most straightforward method of integrating a voltage regulator into a basic power adapter circuit.

Don't lose your cool!

While it is easy to design a 78xx device into an adapter circuit, here's a strong word of caution about the amount of current these regulators can supply: The current values listed in **Table 2** represent the maximum amount of current that can be supplied when they are mounted so that they have adequate cooling. In order to obtain "adequate cooling," you must generally use some form of heat sink to help dissipate the heat generated by the regulator.

Output Voltage	Output Current	Part Number	Package Style
+5	100mA	78L05	TO-92
+5	1A	7805	TO-220
+6	1A	7806	TO-220
+8	100mA	78L08	TO-92
+8	1A	7808	TO-220
+12	100mA	78L12	TO-92
+12	1A	7812	TO-220
+15	100mA	78L15	TO-92
+15	1A	7815	TO-220
+18	1A	7818	TO-220
+24	1A	7824	TO-220

Table 2. Common values of the 78-series of voltage regulators. The "Output Current" column lists the maximum current for a device mounted on a sufficiently sized heat sink. Usable current for the application described in the text is significantly less.

In most cases you will have to forgo any type of heat sink on the regulator if you choose to return the adapter to its original enclosure. Because of this, the maximum current available from a 78xx device in this application should be considered to be only about 25% to 50% of the device's maximum rated current. This is a price you pay for having a wall adapter with a well-regulated output voltage.

Don't blow a fuse!

Besides the regulator and extra caps, you might consider placing another item inside the power adapter's enclosure—a fuse. By fusing the input side of the regulator you will protect the regulator, as well as your project, from an overcurrent situation. Keep in mind, however, that this fuse will most likely be placed inside the adapter's enclosure, so to change the fuse you'll need to take the enclosure apart. This might not be an easy task.

The packaging design: Option #1

Packaging additional electronics into an existing power adapter is the key to a well-regulated supply that still looks professional. This is often an uphill battle, because manufacturers save money by minimizing the amount of wasted (i.e. available) space inside enclosures.

However, opening the power adapter without damaging the enclosure is generally the hardest part of any modification project. To open most adapters you'll need to use a sharp, thin knife or razor blade to cut along the seam between the face plate (the part with the terminals that plug into the outlet) and the rest of the enclosure (the square bowl). If you have yet to purchase

an adapter for modification, try to get one that is held together by screws. Keep in mind that the screws may not be visible; they may be covered by the manufacturer's label, requiring you to hunt for them by lightly running your fingernail over the label.

Packing a regulator and additional components into an enclosure is more of an art than a science, so there is no single recipe for success, but here are some suggestions: For the additional components you need to add into a circuit, try to place as many as possible directly on the adapter's printed circuit board (PCB). This form of mounting tends to increase the circuit's reliability.

In some cases, space permitting, you may be able to mount some components on the bottom of the PCB. This is especially true of smaller items, like filter caps.

Sometimes there are small metal plates mounted inside adapters for various reasons. You can often use this metal plate as a heat sink for the voltage regulator. This will increase the amount of current you can safely draw from the device. Make sure the plate is not electrically connected to other parts of the circuit.

Be sure to use heat-shrink tubing or tightly-wrapped tape around any component leads inside the enclosure. The leads may not be in danger of shorting together now, but components might shift around considerably the first time the unit is dropped onto a hard floor.

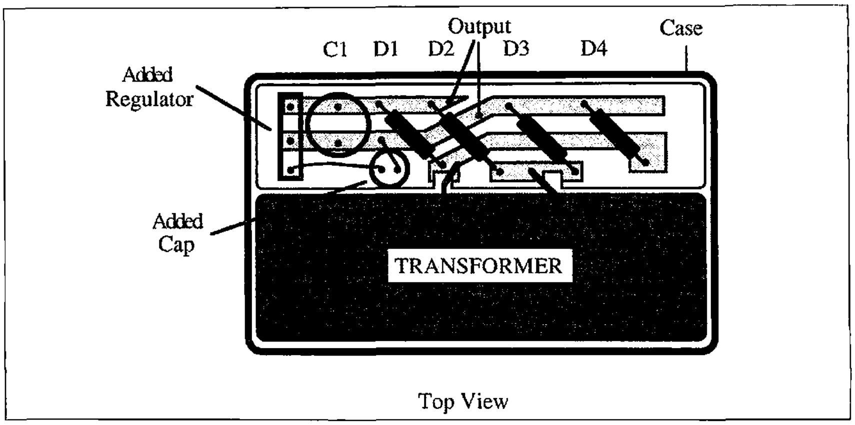

Fig. 5. One way to package a regulator and extra filter capacitors into a power adapter's enclosure.

Once you modify an adapter, run it for a while with the enclosure just taped together, not permanently sealed. Every 15 to 20 minutes of operation under full load, open the enclosure just to make certain you don't have the overheating problem mentioned above.

When you've finished your modifications and tests, reseal the enclosure using Super Glue™ or some other form of adhesive that works well on plastics.

Never modify an adapter rated for outdoor use, even if you plan to use it only indoors. It's too hard to reseal the enclosure in a way that is guaranteed to keep moisture out. Besides, if anyone else were to use the adapter they might see that it's labeled for outdoor applications, and use it as such.

The packaging design: Option #2

There is another packaging option if you are unable to modify an existing adapter case as described above—you can purchase a new case. Many electronics supply companies sell appropriate small enclosures. Some even sell dedicated "wall transformer enclosures." These are small cases with electrical terminals protruding through them that can plug into any standard 120V wall outlet. On the inside of the enclosure, you can generally solder to the terminals, making connection to this project's PC board easy.

If you are interested in this option, check your mail-order parts supplier for different enclosure designs and sizes before you begin the project. Most such cases are very inexpensive, and you might find them a bargain if you find it difficult to open an existing wall transformer case.

A Hamfest Computer Shopping Guide

You can computerize your ham shack for pennies on the dollar if you know how to shop the hamfests.

Alex Piechocki N3JSU
15 Locust Avenue
Towanda PA 18848

With hamfests and computerfests merging, they're getting to be great places to shop for computers. Today there is so much quality computing equipment available at such cheap prices that no one has the excuse not to have several computers in the shack. Indeed, today's hamfests often have more computer than ham equipment exhibitors.

IBM and compatibles with up to a 286 processor are available for under $100, complete and working. And that's with a color monitor, keyboard, disk drives, and up to a 20Mb hard drive. There is a tremendous supply of these machines, and little demand, so they're cheap. They make great packet stations, and will run satellite tracking software and do word processing; they're a great learning tool. Businesses sell their old computers for almost nothing to avoid hazardous waste disposal fees, as demanded by the EPA. Some of them are kaput, but many are just older, slower models which have had to be replaced.

What to look for

First, you want a monitor without a burned-in screen. Next, look at the cooling fan. If it is burned out or wadded up with filth, stay away! Keyboards should also be clean, right down to between the keys. A quick cleanup to cover up years of abuse won't usually get between the keys. Also, the case itself should be reasonably clean. Look for telltale signs of neglect from damp, unheated storage—like rust!

Open up the case and take a look inside. The motherboard (the largest printed circuit board you can see) should be clean, with no dirt buildup or corrosion. Check the battery. If it has leaked and corroded the surrounding chips and wire traces, you don't want the misery.

Check the cards plugged into the motherboard. The connectors should conform to the ISA (Industry Standard Architecture). That means you should have a 62-pin connector next to the back of the computer for connecting to the 8-bit bus.

> ***"The dealer has already made his profit, so any money he gets from the sale of these used drives is pure gravy."***

Next to the 62-pin connector should be a 36-pin connector. This connector, along with the 62-pin one, are used to attach cards to the 16-bit bus. Some manufacturers used custom connectors so their customers would have to buy *their* custom cards. Avoid these computers.

The AT&T-6300 has the 16-bit bus on the other side of the motherboard! IBM PS/2 models 50 and higher have a custom bus referred to as MCA, or microchannel. Parts for these guys are few and far between, and thus are expensive relative to standard ISA boards. The IBM PC Junior is in a class by itself, as are all Apples. The installed cards tell you a lot about what you are getting. Typically on these low-end machines you will have a minimum of three cards. One for the monitor, one for the disk drives, and one for input and output. If there are more, you might be getting a memory upgrade or a turbo processor. All of the chips have their date of manufacture on them, typically the year and week. This can indicate if some of the cards were added later or if everything is original.

Memory is important. The PC and XT computers, with the 8080/8086 microprocessors, could only handle 640K of memory. The 286 machines could address up to 16Mb. It is very easy to tell how much memory you have by checking the chips on the motherboard. Find a section of identical chips; the older machines had two banks of eight chips each of the 256K (total of 512K) and two banks of 64K chips (128K). After the manufacturers identification number there will be a 64, 256 or 1028, followed by a dash and then the speed that these chips can handle. All you need to do to the speed number is to add a zero and you have the speed in nanoseconds. For example, a -15 is 150 ns; a-7 is 70 ns. Speed is important because the faster the motherboard clock's speed, the faster the memory needs to be. If you are running an 8086 at a typical 4.77 MHz, your memory needs to be at least 200 ns. For a 50 MHz system the speed of the memory increases to 40 ns. You also will see that the 64K and 256K chips have 16 pins on them, the 1Mb (1024K) will have 18.

The 286 machines started to use memory called SIPs (Single In-line Package). This memory had the chips soldered on a small printed circuit board that had 30 small in-line pins. The chips used on these

memory boards can be easily removed with some solder wick and a small soldering iron. They can then be transformed into SIMMs (Single In-line Memory Module), which most new computers use today. A vendor might be selling motherboards for $3 each, untested with memory chips still installed; these boards are worth buying just for the memory! I once bought 486 motherboards for $10 each just for the parts. On each board was 256K in cache memory in sockets, which made it easy to remove them. Cache memory, and video memory, are different animals than regular computer memory.

The computer's main memory is referred to a DRAM, dynamic random access. This memory is nothing more than transistor and capacitor pairs. They are dynamic in the sense that the capacitor always wants to discharge, so the computer has to ensure they get charged back up millions of times per second. SRAM (static RAM) or VRAM (video RAM) or SCRAM (static cache RAM) are all the same idea. They are set to digital ones and zeros and stay at this value until externally changed. They are very fast, largely due to more transistors inside for the megabytes they contain, and more expensive, hence you will not see many computers using these for main memory.

Software and documentation are an important part of the deal. "No software" can mean having a computer that can't do anything. All computers have a small software program built into them. The program executes whenever you turn on your computer. It is referred to as the POST (Power On Self Test). This self diagnostic will indicate any number of problems, from a stuck key on the keyboard to bad memory. But after this the most important software to have is the DOS (Disk Operating System). Fortunately, if your computer is really bare bones, down the isle is probably someone who will sell you an obsolete copy for a couple of dollars. PC DOS or MS DOS are the same software—one was written for IBM, and the other was written for IBM compatibles. Both were written by Microsoft. The program has undergone several revisions, with the current one up to version 6.2. The older computers cannot even use the newest version, so the copy of version 3.2 for one or two dollars isn't too bad a deal. Version 5.0, which is very close to the latest and greatest for newer machines, can be had for $5 a copy! Unfortunately, to make good use of the version 5.0, you need a lot of memory and at least a 386 processor.

Documentation is helpful when it comes to setting some of the motherboard's jumpers. If you are planning on doing a lot of tinkering and would like to modify the motherboard, there is hope. Some of the larger libraries have, in their technical section, a book copy or even a CD-ROM of *The Micro House Encyclopedia of Main Boards*. This reference book details all of the switches and jumpers on most of the motherboards you will find.

Upgrades and parts for your PC

Because used computers bring such low prices, many dealers run chop-shop operations. They disassemble hundreds of PCs and bring the parts to flea markets in hopes of making a larger profit. You can get an idea of pricing by checking the classifieds in some of the computer magazines.

The first monitors were black and white (or orange or green) and used an internal MDA (Monochrome Display Adapter) card. They were only good for text. The next monitors were called CGAs, after the internal plug-in card (Color Graphics Adapter). This improved somewhat with the next generation called EGA (Enhanced). the color monitors truly made an important transition when they went to VGA (Video Graphic Array). Hospitals and some industries keep up on the latest technologies; as soon as Super VGA became available, the installed VGA monitors became obsolete. Also, many companies lease computers, and at the end of the lease there is a lot of outdated equipment to be dumped. Refurbished VGA monitors can be bought for around $100 and come in several sizes. I've seen a 12" go for under $75, and the 15" go for $130. Try to purchase brands that you will be able to repair. Schematics on some monitors are harder than others to find. Some schematics are included with the deal, while others might cost you over $50! With any monitor you need a compatible interface card to run it. CGA and EGA cards can be bought for under $15. VGAs, on the other hand, start where the less expensive cards leave off. There's a lot of snob appeal in these cards, so brand names like Orchid and Cirrus tend to increase the asking price as well as the

quality of documentation and the quantity of memory. Since VGA cards can still be bought new for under $50, it pays to keep up with the latest ads. The latest and the greatest is to be able to plug your video card into the high-speed computer bus. This only exists on 486 and newer computers. It is referred to as the Local Bus, VESA local bus, and PCI bus. This is what you eventually would want to graduate to if you have the latest fast-action video games to play. If you like a lot of color resolution, select a video card with at least 1 megabyte of video RAM. The one really neat thing about all of these cards is that they are all downward compatible; in other words, the software that runs on your MDA system will display correctly on CGA, EGA and VGA systems!

Disk drives come in several flavors. The floppy drive on the PC was only capable of storing 360K worth of data. The XT had a version with two floppies; one was a 360K and the other a 1.2Mb. The crazy thing about these was that the magnetic media on the disks were different for each of the disks. That made for easy mistakes in using them in the wrong drive. Therefore you could end up with read or write errors, even though the disk drive was working fine. These large 5.25" drives gave way to the 3.5" 720Ks, which are basically useless today. The standard 3.5", which is on all new machines, provides 1.44Mb. The small 360K drives are available new for $1, so you don't repair these, you just throw them out whenever they fail! The large 1.2Mbs are available for $20 used, and the small 1.44Mbs you can buy for under $30. Most floppy drives plug in via a flat cable to the same driver card as the hard drive. The number one wire is painted red, so make sure it plugs into the number one pin on the drive. If you are running only one drive, the end of the line plug is used. It is the one with the twisted piece of cable next to the connector. This "end" piece is the A drive when you have two floppy drives installed.

Hard drives are a lot of fun. There are many wacky ones out there waiting for you! The earlier ones included on the PC were of the MFM (Modified Frequency Modulation) type. Following these were the RLL and the ESDI, both improvements to the MFM technique. These drives require special formatting to use so removing an MFM drive from a PC and installing it into an AT requires a complete new format! We're talking machine code here, which is not a pleasant task for a novice. Stay away from these old outdated formats unless the drive is exactly the same as the one you have and you've grown attached to its quirks.

The latest and greatest today is SCSI (Small Computer System Interface) and IDE (Integrated Disk Electronics). They both are about the same speed. One sends its data in parallel and can support up to seven devices (SCSI), while the other (IDE) sends its data in serial and can support two devices with the same interface card. I recommend going with IDEs; they install more easily than MFMs and RLLs. They plug into the IDE interface card, which is also plentiful and cheap—typically one or two dollars. New ones can be bought for under $20. IDE drives of 40Mb can be bought for $20 from dealers who upgrade computers. The dealer has already made his profit, so any money he gets from the sale of these used drives is pure gravy. Hard drives are hermetically sealed and designed for 50,000 or more hours of use before failure; however, shock, vibration and heat can lower that. But there should still be many hours left for you to play with.

"A vendor might be selling motherboards for $3 each, untested, with memory chips still installed; these boards are worth buying just for the memory!"

Accessories such as CD ROMs, sound cards and such are available as people upgrade. Single-speed CD ROMs with 8-bit plug-in cards are available new for $25. There's no demand for these when the state of the art is already selling CD ROMs at 8X speeds. People are conditioned to think that single-spin is too slow. Believe me—a single-spin CD player will still locate that callsign for you faster than using the book, and you have the added benefit of playing your favorite musical CDs too. Sound cards are available as people upgrade to the latest and greatest in multiple voice polyphony. After years of listening to single sideband, an 8-bit sound card will sound heavenly. But don't stop here—16 bits is the standard, and again, if you shop around you can find these at bargain basement prices.

Building your own computer

Over $10 billion in hardware is out there getting obsolete. Some of it will find its way to your local hamfests for pennies on the dollar. What a temptation to build a system that is really unique, teaches you a new skill, and does something useful for you around the house or shack.

Remember, with computers running in the RF range you need good grounding. If your enclosure has sturdy grounding fingers, along with liberal amounts of stainless steel wool on the edges, then when you transmit your RF will not get into the computer and confuse it or shut it down. This will also keep the computer from messing up your receivers.

The best way to build your own is to start out with a cheap system. The 286 computers came with good power supplies. Be very wary of the high volume computers such as IBM, Dell, Compaq, and AT&T, since only large companies can afford to build nonstandard, one-of-a-kind parts. Almost all of the other computers use generic parts.

Most power supplies are identical. They are all switching supplies, and even the connectors to the motherboard are the same. Just remember to put the four black ground wires in the middle if your supply has two plugs.

The one thing to pay attention to is watts. The very early computers were small; only 85 watts. Try for something up in the 250-watt or more range. Accessories take lots of power. Once you have a computer with a good power supply, case and disk drives, all you need is to replace the motherboard and you can say you built your own. Motherboards are relatively inexpensive, even if you buy a new one. New motherboards are tested and warrantied, and go for $50 or less for a 486 type. You can buy these boards minus the processor chip, which is the big money. Look around at the 'fests for processors. Since many people upgrade, you can find 486-SX 25 MHz processors for

$20 to $30. That is the bargain way to start. You can always upgrade with the faster DX-2s, 3s and 4s later.

First, you should be aware of how these processor chips are different. All Intel 486 chips are made the same. It is in the testing that they are given their labels. The SX label is for 486s that had defective math coprocessors, which are for floating point math. The only programs that use it are engineering work stations, computer assisted design (CAD), and some spreadsheet programs. Most games don't use this processor since they don't need the precision or the resulting slower execution speed. To upgrade the SX with a math coprocessor you have to buy a 487 chip. This chip is a DX chip with an extra pin on it to disable the SX chip (pretty sneaky, eh?). The 486s are warmed up and run at a high clock speed at the factory; the ones that pass error-free get the highest ratings. The ones that fail are re-tested at a slower speed. Thus you have your DX-50 MHz, DX-33 MHz, DX-25 MHz, etc. The same holds for SX too.

Some motherboards let you change their clock speed with little jumpers, some with software, and some need to have the on-board clock chip replaced. Make sure your motherboard can run at the speed of your chip. If you only run your computer for a short time, or slap a big heat sink and fan on the chip, you can juice up the clock speed and run faster than the numbers painted on the chip. I've run my 25 MHz chips at 33 MHz with no errors. Just put your finger on the chip under load ... if it feels hot you will shorten its life, but if it is cool to the touch you shouldn't have any problems. The DX/2 series plug into the same socket as the other 486s. It is worth it to pay a few dollars extra for a ZIF (Zero Insertion Force) socket. Then you can change your processor with no effort in seconds. Just remember, there is an alignment dot that needs to be followed. Sometimes it is a squared off corner, so follow it to ensure you put the processor in the right way.

The DX/2 and /3 and /4 all have frequency doubling, tripling, or quadrupling circuits in them. The reason it makes your system faster is that when an instruction is sent to the processor, the processor can take many clock cycles to decode and act on the command. But it only takes one cycle to bring in instructions from the motherboard. So, to set the frequency on the motherboard for these chips, divide the chip frequency by its multiplying number. The DX/4-100 is run at 25 MHz; the DX/2-66 at 33 MHz. After everything is put together it is amazing how these systems start right up.

Digital electronics does not have all of the tweaking that analog does, but there will be some small details to attend to before you will be on your way. All motherboards have some form of setup. The earlier boards used jumpers. This evolved to software disks, to the point now where the setup is part of the system's BIOS (Basic Input Output System). Remember those POST error signals (beeps sort of like Morse code, or an on-screen message to tell you your error)?

When you start up you have the opportunity to go into the computer's CMOS setup. This is a couple of chips that use very little power and have the on-board battery feeding them when you turn off the computer. When you go into the setup you tell the computer what you have attached to it. You type in the size disk drives that you installed, the amount of memory on the board, what functions you want the motherboard to use, such as clock speed, cache controller, etc. You can usually wing it, but having some documentation on what and how sure make you feel more comfortable as you are typing.

Sometimes your system may appear to be dead on startup. The boards you installed might be set to the same address or interrupt (IRQ). Simply remove all of the cards, with the exception of the video one, and gradually start putting them back until you find the conflict. This type of problem doesn't usually happen until you put the CD-ROM, sound card, mouse driver card, game port, and fax modem cards in. There is a good chance that the computer is trying to talk to two or more cards at once. Computers may be fast, but they still need to communicate to the input and output one at a time.

This has been a whirlwind tour of computers, by no means complete. Even if you are planning to purchase new, going to the dealer with some basic knowledge of computers and the prices of the various components can help you drive a better bargain. I hope I will be seeing you at the flea markets, having as much fun as I do, recycling computers and keeping hazardous waste out of our landfills.

A Retiree's HF Mobile Installation

This style of hamming ain't exactly hard to take.

Bert Simon K2FZ
2110 NW 45th Ave.
Coconut Creek FL 33066

After having lived on boats for 15 years, the concept of a mobile HF installation was so embedded in my failing brain that when the time came to give up boats and become a landlubber, I knew that the dreaded ham virus would force me to acquire a good HF mobile station. Selling my boat put me in a position to choose, within reason (my wife said it was OK), the vehicle, the radio and the antenna.

The vehicle

I envisioned a vehicle that would contain a small desk for writing, reading and hamming. A comfortable place to recline would be kind of nice, for resting the eyes when the need arose (which happens rather frequently as one nears the QCWA second cluster category). I chose a "high-top conversion" type van which came complete with four captain's chairs and a bench seat that folds down to become a bed at the flip of a switch. A sturdy desk was installed behind the driver's position and *voila!* A very comfortable vehicle where every day can be a "Field Day." Three additional batteries, of the gel cell persuasion, were installed, along with battery safety/disconnect circuit breakers. A digital voltmeter is being constructed to provide close voltage measurements, important in making a battery's life long and prosperous. Additionally, a through-the-ceiling fan was installed and is generally in operation when the van is parked. I haven't found it necessary to charge the batteries after three hours of hamming and ventilating, but then again, so far I haven't operated more than three hours at a stretch.

"The marine channels might come in handy if I'm ever marooned by a rising tide."

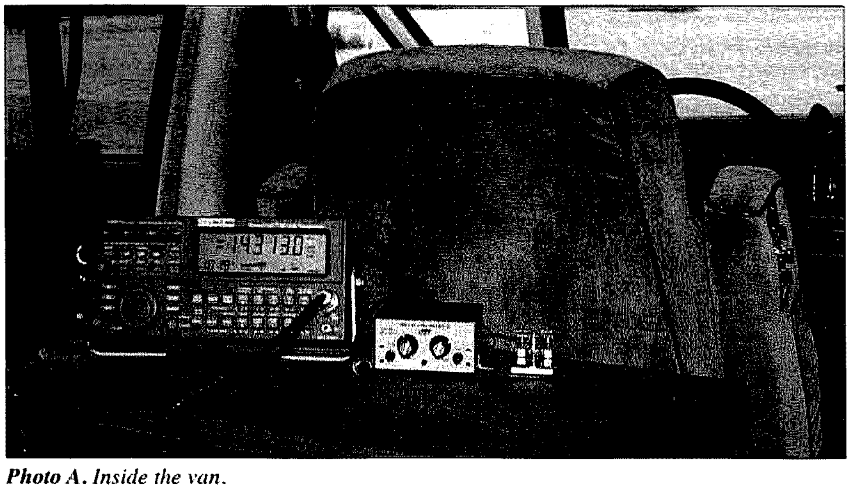

Photo A. Inside the van.

The radio

The latest breakthrough in HF communications appears to be DSP (digital signal processing) in which, due to the wonders of science, the gershmeckda signals go through an amorphous transition into a digital conglomeration completely alien to humans. It is then magically transformed back into supposedly intelligible signals. Considering that this radio might be my last big ham purchase before being recalled from this planet, I decided I might be remiss if I didn't become a DSPer. Other considerations involved money as well as the weight of the radio (some of the very sophisticated radios weigh in at 30-plus pounds and get into the three-plus kilobuck category). I decided it would be best to keep the "radio footprint" to a minimum and so decided on a remotely-operated rig.

The radio which met my criteria was the SG 2000 with Powertalk head (DSP, that is), made by SGC of Bellevue, Washington. The price was under three kilobucks and the radio weighed 12 pounds, which didn't make any difference since the remote head, which was the device to be table-mounted, was only about two pounds. This radio has

nice features, such as over 600 marine channels programmed into its memory. I figured this might come in handy if I'm ever marooned by a rising tide—I can always call the Coast Guard. The radio also comes with over 60 ham frequencies programmed, which mainly represents the band edges as well as other convenient frequencies used for ham mobile/marine operations. Additionally, 60 other frequencies may be programmed in according to individual requirements. But heed these words of caution: This radio is not for every ham and there are those who may find some of the operating features are less than ideal for typical amateur operation—if one allows four seconds to go by without using the main frequency dial it is then necessary to press the "FREQ" button, sometimes more than twice. When this button is pressed, the radio beeps to announce that the button has been pressed and the tuning knob is now operational; it's not exactly a "contest" radio. As for CW, I have found it unusable due to the delay of the AGC response. I have discussed this problem with SGC and am awaiting their recommendations. For now, I am able to use the radio on CW by providing an MFJ keyer with an audio tone, and then feeding the tone signal plus an additional pair of leads to a big old-fashioned switch. Both sets of leads are wired to a separate microphone connector. The other item which takes a bit of getting used to is the CW DSP operation. The apparent bandwidth in this mode is very sharp and in order to be able to switch the DSPer from the broad mode to the sharp mode it is important to receive the CW tone at approximately 1000 cps. I find that I'm not always able to select the tone accurately enough to fall within the passband of the filter. Again, it's not exactly a contest radio.

There are approximately 30 push-button functions to this radio and the DSP version has an additional eight push-buttons plus some added knobs. I admit it would take a better man than I to operate this radio and still survive bebopping down the road at 65 miles per hour. In fact, in my degenerative condition I find it somewhat exasperating to locate the necessary buttons (let alone execute them) before the telltale sound of the beeper announces that the four-second period is up and I must start over again. (Perhaps a neuron transducer can be added to activate my sole operating brain neuron, which might enable it to move fast enough to avoid the dreaded four-second announcement.)

"If I didn't require a stool to stand on, I could probably install the antenna in less than a minute."

Now, with all my criticism regarding the SGC 2000, one might think that I don't like it. *Au contraire, mon ami.* The radio, in spite of its faults, does have its charm, although I do believe that it, along with SGC's QMS mobile antenna and its "20 dB advantage," would be best suited for a non-technical/non-ham paramilitary-type operator.

The antenna

I have found Don Johnson's book on HF mobile installations to be a wealth of information. Additionally, valuable mobile antenna comparisons are contained in *QST* and *Worldradio* issues. The "HF Mobile Shoot-Out" described by *Worldradio* compares the relative radiation of 17 HF antennas ranging from those having center-loading coils with and without top hats to the SGC-QMS (20 dB advantage) bottom-loaded antenna. The high Q center-loaded type won hands down, with those having top hat devices showing a 2 or 3 dB advantage over the less grotesque center loaders. The worst antenna was the one which was advertised as "the 20 dB advantage." It measured about 10 dB *less* than the typical center-loader. Quoting Gilbert and Sullivan: "Things are seldom as they seem." My advice: Beware of extravagant claims.

I had decided that an antenna that could be remotely tuned to continuously cover the entire 80 through 10 meter spectrum and have a high Q center-loaded coil would be my choice. I investigated two of the several companies producing such antennas: T.J. Antenna Co. of Hermiston, Oregon, and High

tenna Co. of Hermiston, Oregon, and High Sierra Antennas of Nevada City, California. They appeared to have similar products, all based on the Don Johnson design. I chose High Sierra because they had available a type of mount which allowed the antenna to be readily removed. In fact, I can remove and/or install the antenna in less than three minutes, but if I were as tall as a basketball player and didn't require a stool to stand on, I probably could do it in less than a minute.

High Sierra makes several types of mounts and they can also manufacture just about any mount to suit individual requirements. Their mounts are of heavy-gauge steel construction and are attractively painted black, which closely matches the type of rectangular aluminum extrusions used in condo "screened-in constructions." I decided to use High Sierra's mount and join it to a two- by three-inch aluminum extrusion (readily available at large hardware stores). I joined the aluminum extrusion and the "Universal Mount" from High Sierra with #14 SS self-tapping screws and star washers which provided rigidity and good electrical bonding.

I was able to mount the antenna without drilling any holes in the van by using U-bolts to fasten the aluminum structure to the spare tire supports. I recommend using proper HF practice and making certain that there are good grounds between the supporting structure and the vehicle, but then again, just follow Don Johnson's advice and you'll have a good installation. Truthfully, I am not absolutely certain how my signal would be affected without the proper grounds, but I'll put it in the same category as the test for pearls: "Place the pearl in a container of vinegar and if it dissolves it was real." The only holes I drilled in the van were the ones to provide the DC voltage and the coax feed to the antenna; I thought it looked better than having wires dangling in the wind whenever the antenna was not in place.

One other advantage of this radio and antenna combination is its ability to tune in all kinds of other HF activities—SWL broadcasts, marine stuff, etc. Having a continuously tunable high Q antenna covering all the frequencies from 80 through 10 meters really makes for excellent reception.

The end result

I am thrilled with the entire mobile operation. I compare it to my base station, which is an ICOM 735 using an ICOM AH-2 remotely-operated antenna tuner. This particular setup is my condo HF station and employs about 17 feet of wire as the antenna plus about five radials, installed under the carpet of the ham shack, which range from five to 10 feet—not a very good installation but at least it's hidden from the eyes of the condo commandos. I find that I am able to receive more signals and more DX from my mobile when parked right next to the condo, as compared to the condo base station. A good indication of the mobile's performance is the amount of returns I get from calls made; it's much better than that of my base station. The antenna tuning is remotely controlled by an up/down switch conveniently installed near the radio and the built-in SWR indication of the SG 2000 works well, although it does require the pressing of two buttons to activate the SWR function. The "SHFT FUNC" button must be pressed before you can press the "FWD-SWR" button. I wouldn't recommend tuning the antenna while driving—however, the usable bandwidth on 20 meters is quite adequate, about 200 kHz without requiring retuning. I attribute the success of my mobile installation mainly to the quality of the High Sierra Antenna and the sage advice in Don Johnson's book. I must also give credit to SGC because I have frequently been told that I have excellent audio quality.

Life is good. ■

NEVER SAY DIE
Continued from page 59

nation, under God" stuff. Hmm, now that I think about it, that "Under God" part got added later. Our pledge of allegiance when I went to school never mentioned any deity.

For that matter, the pledge never meant anything either. If the United States was viewed as good we'd support it. Considering the problems we face today, it is getting more and more difficult to feel anything strong about our country. The main thing it has going for it is that, as terrible as things are, they seem to be worse most other places. But that's not something I'd willingly lay my life down for. If you don't chew gum, spit on the street, spray-paint cars, or pee in elevators, Singapore has a lot going for it.

During WWII I had no problem in volunteering for the most dangerous duty there was because I really didn't care much whether I lived or died. Recent research has shown, as I've mentioned, that this was the result of the childhood beatings by my father. This is one of the major causes for teen suicides. Luckily I underwent some brain repairs when I was 28 which got rid of all that crud and changed my life.

Please, let's stop zealots from trying to use the government (and our federal judges) to further their religious goals. I'd also like to get the government out of social engineering too. Not one program has worked, but that's not enough to stop the under-informed from pushing to spend more of our money for their pet projects.

Oxygen

The largest organ in our bodies is our lungs, and they're there to bring oxygen into our systems. We burn oxygen for fuel. Plus, more oxygen in our blood helps kill off microbes and viruses. Now do you suppose that there's any connection between the dropping percentage of oxygen in our air and the recent increase in all kinds of illnesses? It might even tie in with the increase in gutlessness and lack of creativity shown by our younger generation since oxygen is critical to the brain's operation.

How much oxygen have we lost so far? A couple hundred years ago our air had 38% oxygen. In the 1950s it was down to 21%, and now it's down to just over 19%! Worse, in the cities it's as low as 9%, due to the extensive heating of buildings by burning fossil fuels, the thousands of cars and trucks, and even millions of people breathing.

One of the benefits of jogging is that it forces us to breathe more heavily and bring in more oxygen. Dr. Douglass, of *Second Opinion*, has a great book out on how to prevent aging. In it he recommends breathing pure oxygen every day while exercising as a way to reverse the aging process. Adding
Continued on page 82

NEVER SAY DIE

Continued from page 81

oxygen to our bodies seems to help beef up our immune systems, which in turn can help reverse arthritis, cancers, and other annoying breakdowns of the body.

It seems to me that if you can even remember every now and then to hyperventilate, that's going to being more oxygen into your system. But I know how difficult it is to remember to breathe.

When we get tense our tendency is to hold our breath, making it even worse. There are few headaches that can't be cleared up by hyperventilating—getting more oxygen into your system, where it first goes to your brain, and then to the rest of your body. The brain uses a surprising amount of oxygen, so when we cut down the brain is one of the first parts to malfunction.

The decreasing oxygen percentage in the air means a higher percentage of nitrogen (and a much higher percentage of CO_2), leading to an increase in nitrogen narcosis, the "rapture of the deep" it's called when you're diving. It's a gradual loss of reality, but one which is not noticeable by the individual involved. Maybe you've noticed a lot of that going around.

If you've read anything about breathing you know that just as we gradually lose the flexibility of our eyes from focusing them at one distance or direction so much of the time—reading, computering, TV watching—we also lose a great deal of our lungs' capacity to bring oxygen into our bodies by shallow breathing. Every so often exhale completely and then suck in as much air as you can into your lungs and hold it for a few seconds. Then completely exhale again. Use more of your lung capacity whenever you think of it. And hyperventilate to make up for all that oxygen that's no longer in your air.

I see where in Beijing there is a flourishing business in selling oxygen. They have booths where you can breathe 50% oxygen for $6 an hour. That's something which could do well in our more polluted cities such as L.A., Denver, and New York.

The Value of College

A recently released study showed that the $40,000 investment for a college education results, on the average, in an increase in lifetime earnings of $300,000. Hey, that's almost a 10-times gain on your investment! No wonder parents are so anxious to get their kids into college. Yeah, except for one little tiny thing. If you take that same $40,000 and invest it in something safe that returns 6% you'll end up with $550,000.

Big corporations put a good deal of stock in your college degree when they're hiring, but few small companies give a hoot. They want to know what you can do for them, not where you went to school. And working for a large company is one way to pretty well assure that you are never going to make any serious money. I keep mentioning the *Inc.* magazine survey which showed that virtually all of our more successful entrepreneurs either skipped college entirely or dropped out in frustration after a year or two. College does help the unmotivated to make more in dead end jobs, but seems to be a waste of time and money for anyone with the determination to succeed. So much for the election oratory about how everyone should be able to go to college. For what? Just to keep them out of the labor market for four more years at public expense and further dumb them down and demotivate them?

I tried hiring RPI graduates for my company and was appalled at their lack of skills or even any interest in acquiring skills. I went to the university and interviewed graduates, looking for the most promising. Most were incredible duds and not worth even trying. The few I ended up giving a try were unmotivatable.

When I started *73* I used to hire college dropout hams and teach them the publishing business, and they were eager to learn. Some have gone on to excellent careers as a result, doing very well for themselves.

Just as anyone with the right help can learn to read and write in a hundred hours (according to the top prize-winning New York State and New York City teacher John Gatto), anything of value one can learn from going to college can be learned in a tiny fraction of the time by reading books by the world's top experts (who beat the heck out of the professors most colleges provide). Our colleges, like our grammar and high schools, are a mess.

Schools

Just in case your only reading matter is the ham rags and your TV set is broken, I'm going to rub

your nose in what a mess you've let our schools get in. It's bad enough that you're screwing up your life with that garbage you've been eating and sewage you've been drinking, but in addition to teaching your children to eat and drink the same destructive stuff, you've also allowed our school system to disintegrate so they are being mentally poisoned and stunted. Hey, don't look around for someone else to blame. And none of this gee, what can little me do about big problems like that?

Now let's look at some facts of what you've sheepily let happen, and most of it has been done with the money our beloved government has taken out of your pocket and spent for you. You can't name one single job the government is doing that can't be done far better and at less than half the cost.

The government loans for students have helped zoom college costs. $24 billion today, and headed for $36 billion in five years. All not just a total waste, but a poisoning of the educational well. I won't repeat again my simple plan which would completely eliminate college tuition and at the same time enormously improve what students are learning, making it infinitely more practical and useful in the *real* world.

In the past 15 years, while the Consumer Price Index has risen 74%, college tuition has risen an average of 234%. In 1979 the cost of a college education (already inflated) equaled 21% of the average family's income. It's now 39%. Tenured professors earn an average of $60,000 annually for 18 hours a week of work, 30 weeks a year.

From 1975 to 1985, while student enrollment grew 10%, the non-teaching staff (like deans) grew by 60%. And in the last 30 years the academic year shrank from 191 days to 156.

At a majority of the top 50 colleges listed in *US News and World Report* students can graduate without taking a single course in math, science, English, history or literature. The Hudson Institute reports that American schools are now awarding more degrees in home economics than math and more in protective services than in all of the physical sciences.

A federal study showed that 56.3% of the graduates of four-year colleges couldn't calculate the change they'd get back from $3 after buying a 60¢ bowl of soup and a $1.95 sandwich. Parents are spending fortunes on four years of expensive baby-sitting, and we're all forced by law to support this mess. Or else go to prison.

American students rank #1 in the world in how good they feel about their math skills, but a 1992 international study by the Educational Testing Service showed us ranking last in math achievement (well behind Slovenia). In 1972 28% of college-bound seniors had an A or B high school average. By 1993, 83% had an A or B average, while at the same time their SAT scores were plummeting. Now the educational establishment, to cover its dirty tracks, is planning to "re-norm" the SATs, since they've gone down permanently.

The students with the lowest SAT scores become education majors. Students who earn education degrees have lower scores on all the accepted tests than any other major than social work. They don't read, and few can write a coherent letter. On the average, our teachers read one book a year, and that's a fiction book.

More money isn't going to cure this mess. Paying dumbed-down teachers more isn't going to make them better. Creating even more administrative layers isn't going to help our kids.

Why did you have a kid anyway? Your kids are probably the *only* mark you're going to leave on the world to record your having been here. Why are you teaching them to eat garbage and drink sewage? Why are you putting them into our cesspool public schools?

Maybe you've read that parochial schools cost about a third as much as our public schools per student, and teach them far more. Probably not.

So what can you do about this mess? Start at the heart of it: your government. Get out there and vote, making sure that you Never Re-elect Anyone (NRA). And get your family and friends out there to do likewise. Let's flush that Congressional toilet we've allowed to stop up and stink. Step two is to get some ham friends to run for your state legislature and re-elect the heck out of them. Let's infiltrate the system and start hacking back

More Fun Than Rabbits

If you've played with the FCC part 15 "rabbits" you'll find that this new ATV transmitter from PC Electronics will allow much greater scope and reliability. The new TX33-1b 33cm band (902-928 MHz) 1 watt transmitter is sturdy, accepts video from most camcorders, cameras or VCRs, and has an 11-mile snow-free line of sight DX. A video monitor jack lets you set up focus and lighting before you transmit, then shows you your video so you can fine-tune.

It's compact, rugged, and surprisingly inexpensive, at $329 (including shipping in the contiguous USA). If you're a licensed ham, contact PC Electronics by phone, snailmail or E-mail for details at 2522 Paxson Ln., Arcadia CA 91007. Phone (818) 447-4565; E-mail tomsmb@aol.com.

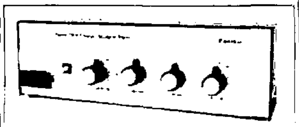
I'll Take One of Each...

The new Contact East catalog supplement is 48 gorgeous full-color pages of test equipment, tools and supplies for engineers, hobbyists, managers and technicians. All the brands you trust, all products fully guaranteed, and Contact East promises same-day shipping on orders placed by 4PM. To get your free copy, call (508) 682-2000; FAX (508) 688-7829; write Contact East, Inc., 335 Willow Street, North Andover MA 01845.

Alinco Responds to Ham Needs

The new DX-70TH was created for hams who've enjoyed the features of Alinco's popular line of amateur equipment, but have wanted more. Well, here's more! The new model maintains all the features of the DX-70T mobile/portable/base unit but increases the output on 6 meters to 100 watts (the DX-70T has a 6 meter output of 10 watts).

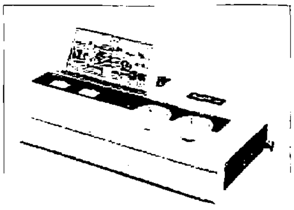
Priced at $1,074, the DX-70TH can be used as an all-mode (SSB, CW, FM, AM, and Data) radio in mobile/base/portable environments. A mobile mounting bracket is included, and many other accessories are available. See your dealer for more information or write Alinco, 438 Amapola Ave., Ste. 130, Torrance CA 90501. Phone (310) 618-8616 or FAX (310) 618-8758.



Field Strength Meter

Palomar Engineers announces a new field strength meter, Model PFS-1, for serious antenna work. It features a detector linear over nearly a 30 dB range, an accurate step attenuator with 30 dB range, a 25 dB RF amplifier, high Q tuned circuits to suppress out-of-band local signals and a panel meter readable to .1 dB.

The meter covers 1.8 to 150 MHz and is powered by 9- or 12-volt batteries. Antenna connection is an SO-239 jack on the rear of the aluminum cabinet. All this, and the PFS-1 is priced at only $195! For further information, contact Palomar Engineers, P.O. Box 462222, Escondido CA 92046; Phone (619) 747-3343; FAX (619) 747-3346; E-mail 75353.2175@compuserve.com.

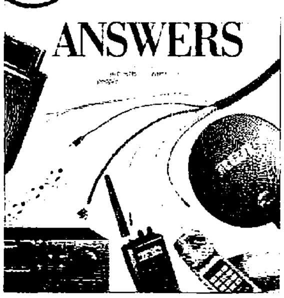


In Synch

Need to synchronize your station to absolute time? TrueTime has an affordable solution: The TimeLink 3 (TL-3) is a precision real-time clock that receives three channels of WWV radio-transmitted time signals simultaneously. Transmissions are synchronized to the National Institute of Standards and Technology Atomic Time Standard. The TL-3 outputs time on a Display, RS-232 I/O port, IRIG B serial time code, audio speaker and a 1 PPS. Computer software drivers are available for DOS, Windows, Windows NT and Novell Netware—and all this, including the antenna, is only $549! For more information contact: TrueTime, Inc., 2835 Duke Court, Santa Rosa CA 95404. Phone (707) 528-1230; FAX (707) 527-6640.

New Multiband Dipole Antenna

Dynamic Electronics Inc. announces their new multiband antenna for HF and VHF. The DP-1 covers 80, 75, 40, 30, 20, 17, 15, 12, 11, 10, 6, and 2 meters. It's 125 feet long and has a maximum width of 2 feet. This 8-dipole element trapless antenna has wide bandwidth on each band and can handle maximum power, and it is $129 plus $6 shipping and handling (US and Canada). Also available is the DP-2, which covers 40, 30, 20, 17, 15, 12, 11, 10, 6, and 2 meters. The DP-2 is only 65 feet long (maximum width 2 feet), and is priced at $110 plus shipping and handling. For more information, contact Dynamic Electronics, Inc., P.O. Box 896, Hartselle AL 35640; (205) 773-2758; FAX (205) 773-7295 or check it out at HTTP://www.hsv.tis.net/~dei.



Need Answers?

Here you go! The 1997 edition of *Answers*, the new RadioShack™ catalog, is available now. It's 280 pages of what you'll find at more than 6,800 dealers across the country—plus the hundreds of products available through RadioShack Unlimited, a special order program that gives customers access to more than 100,000 unique and hard-to-find personal electronics products, parts and components. *Answers* is an easy-to-read reference tool that helps take the mystery out of electronics, for only $2.95.

It's Free!

If you've been looking for a club involving radio here's a new guidebook that may be just what you need, especially if your QTH is in the Southeastern United States. The *Radio Hobby Clubs Pocket Guide* lists more than 50 clubs, including ham radio clubs, scanner clubs, CB clubs, and a radio-related computer bulletin board. Radio hobbyists will find club addresses, contact phone numbers, meeting places and times, and radio frequencies for the West Central Florida area.

Anyone interested in radio can get this handy little (5-1/2 x 4-1/4 inches) guide by sending name, address, and two first class stamps to: RADIO CLUB GUIDE, P.O. Box 103, Largo FL 33779-0103.

Handbook on CD-ROM

The ARRL Handbook CD ($49.95) will simplify searching for information in this PC version (Windows/DOS) of their massive yearly handbook. It includes sounds bites to illustrate various modes and activities. For some uses the paper edition ($38) is better, but with the CD edition you get many active programs for calculating antennas, feedlines, etc.

Get both.

QST on CD!

The back issues of *QST* are now available on CD, from 1970 through 1994. Each four-year group costs $39.95, putting 24 years of the magazines into one small CD wallet for you. Yes, they're working on ROMing the earlier issues. What a great way to search for articles! This is like an encyclopedia of amateur radio. Yes, the columns are there too.

More Antennas

The ARRL has announced Volume 5 of their Antenna Compendium series. It includes 41 articles and a disk (IBM format) with data for use with antenna plotting and modeling programs. $20.

Never say die

Continued from page 83

the forest of rotten laws we've allowed Congress to use to steal our money and spend it on stuff that is ruining what could be one heck of a country.

If you just nod and sit there, nothing is going to change for the better, but we know from history that it is going to keep getting worse, and our kids are so poorly educated and stripped of creativity and guts by our schools that they're going to accept whatever comes along, the same way you have.

Sermon over. Oh yes, thanks to Walter Williams and Don Feder for the statistics I stole from their columns.

Magnetic Healing?

I've read a good deal about the power of magnets to help the body heal. I've even reviewed a couple of books on the subject, and I have a good friend I met at the Global Sciences Conference in Tampa earlier this year who is an expert on the subject. So I wasn't completely surprised when I got a letter from a reader who was active in the early linear accelerator days.

He explained that the researchers for General Atomic, working on the linear accelerator for Lawrence Livermore in San Francisco, were surprised when their magnetic doughnut-shaped coils collapsed the copper tubes the coils were wound around when the capacitors were discharged into the coils. They didn't know that nonmagnetic materials such as copper, brass and aluminum could be formed by a high energy impulse magnetic wave. Once they discovered this they sold units to several companies for forming parts.

In the early days of testing the equipment one technician didn't want to bother setting up a special jig, so he just held the part to be formed in his hand and let loose the magnetic blast. His hand got a severe burn that should have taken at least six months to heal. A few days later it was healed. They tried to interest people in the medical field, but got nowhere.

One of their people got his ankle shattered while skiing in Nevada. Gangrene set in so he was flown to a hospital in San Francisco, where they wanted to amputate. Friends brought him to the magnetic unit and two days later the gangrene was fading away. When the doctors went to operate the ankle had healed. The medical community refused to look at what they'd found.

If you've read any of the books I've recommended on the medical industry this will not surprise you.

Bioelectrification

Reader Baluch in Ohio wrote to say that he had taken a shortcut with the bioelectrifier. He used two dimes, a 27V battery (three 9Vs) and a microammeter and didn't bother switching polarity. He just tapped the current on and off. He said that he started losing weight immediately and is now down to his normal weight, his memory has improved (he's 72), and he's looking for some hair to start regrowing next.

Well, Bob Beck grew a new head of hair, so who knows? And then there's that chap who was struck by lightning and grew new hair *and* a new set of teeth. ■

Updates

Frank speaks

... a far, far *brighter* thing I do ...

This comes from J. Frank Brumbaugh concerning his November '96 article, "A Low Current Light":

"After my article descended into the depths of the magazine's computer system, I discovered a source of brighter yellow LEDs: All Electronics, PO. Box 567, Van Nuys CA 91408-0567; Cat. #LED-29; four for $1.00. These are T 1-3/4 yellow LEDs, water clear, 2.1 volt at 20 mA. Each produces 550 mcd light level, much brighter than the diodes specified in the article. Use five LED-29s in series with a 120-ohm 1/4W resistor for a far brighter light source." ... J. Frank Brumbaugh

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the April issue, we should receive it by January 31. Provide a clear, concise summary of the essential details about your Special Event.

JAN 11

LOVELAND, CO The Northern Colorado ARC will host their Winter Superfest 9 AM–3 PM at the Larimer County Fairgrounds, 700 Railroad Ave. VE Exams, commercial exhibits, computer and radio goodies, more. Reserve tables from *Jeanene Gage NØYHY (970) 351-7327*. For general info, call *(970) 352-5304*. Talk-in on 145.115(-) 100 Hz.

PHOENIX, AZ The ThunderBird ARC will host the WestFesT-West Valley Hamfest at Glendale Community College, North Lot, 6000 W. Olive (Dunlap & 59th Ave.), starting at 6 AM. The event is being sponsored by the Amateur Radio Council of Arizona. Free admission, parking $2, tailgaters $5. Talk-in on 154.43- 146.52. Contact *Mark KC7BXS, (602) 931-1204;* or *Ralph WØDNO, (602) 582-8208.*

JAN 18

ST. JOSEPH, MO The Missouri Valley ARC, Green-Hills ARC and Ray-Clay ARC will sponsor the 7th annual Northwest Missouri Winter Hamfest, 9 AM–4 PM at the Ramada Inn. The motel is located at I-29 and Frederick Ave. (exit 47 on I-29), and is offering special rates for hamfest participants. Major exhibitors and flea market all indoors. Free parking. Admission by pre-reg. is $2 each or 3 for $5; at the door, $3 each or 2 for $5. Pre-reg. requests received after Jan. 8th will be held at the door. Swap tables $9 each for the first two tables. Commercial exhibitors welcome; write for details to *Northwest Missouri Winter Hamfest, c/o Gaylen Pearson WBØW, 1210 Midyett Rd., St. Joseph MO 64506.*

JAN 19

BROADWAY, OH A Winter Ham Radio Fair will be sponsored by the Union County ARC 8 AM–3 PM, on State Hwy. 347 three tenths of a mile west of State Route 31. Free parking. Tickets $2 at the door; no advance sales. Age 16 and under free. 8-foot tables $10 for full length, $5 for half. Reservations are encouraged. Please forward payment with an SASE to *Union County ARC, c/o Gene Moore N8YRF, 24461 Claibourne Rd., Marysville OH 43040. Tel. (937) 246-5943.*

RICHMOND, VA The Richmond Amateur Telecommunications. Soc. will hold "Frostfest 97" at the Showplace, 3000 Mechanicsville Tpke. I-95, exit 75 to I-64 East, then exit 192 (Rt. 360 East), go 1/2 mi. on left. Hours 8:30 AM–3:30 PM. Indoor dealers' flea market, forums. Wheelchair accessible. Talk-in 146.88/28. Admission $5. Dealers' tables $35, flea market tables $15 (must RSVP by Jan. 4th). *Contact Craig Spain, (804) 526-9838 eves., or write Richmond Frostfest '97, P.O. Box 932, Chester VA 23831.* For general info, call *(804) 739-2269, ext. FEST. Internet at http://frostfest.rats.net.*

YONKERS, NY A Giant Electronic Flea Market will be held by the Metro 70cm Network 9 AM–3 PM at Lincoln H.S., Kneeland Ave., Tel. (914) 969-1053. Doors open 7 AM for vendors, 9 AM for buyers. New and used equipment for CB, amateur radio, commercial two-way, computers, stereo buffs, electronics parts and kits, plus much more, will be on sale. Donation $6, kids under 12 free. Table setup at 7 AM. VE Exams 9 AM–11 AM. Contact *Otto Supliski WB2SLQ, (914) 969-1053.* Talk-in on 449.425 PL 156.7; 223.760 PL 67.0, 146.910 Hz, and 443.350 MHz PL 156.7. Mail reservations to *Metro 70 CM Network, 53 Hayward St., Yonkers NY 10704.*

JAN 26

DOVER, OH The Tusco ARC Hamfest will be held at the Ohio Nat'l. Guard Armory, 2800 N. Wooster Ave., starting at 8 AM. Setup starts at 6 AM. Admission $2 donation at the door. Tables are $8 each. For info and tables, contact *Tusco ARC, c/o Howard Blind KD8KF, 6288 Echo Lake Rd. NE, New Philadelphia OH 44663.* Please bring your own extension cords. 120 volts is available. Send reservation orders by Jan. 12th to *Tusco ARC, c/o Howard Blind KD8KF.* Talk-in on 146.730(-)

JAN 28

ODENTON, MD A Post Holiday Swapfest and Flea Market will be held by the Maryland Mobileers ARC 8 AM–2 PM at The Odenton Vol. Fire Dept. Hall, 1425 Annapolis Rd. (Route 175). Free VE exams, pre-reg. with *Jerry Gavin NU3D, (410) 761-1423.* Talk-in on 146.205/.805. Donation $3. Tables in advance $7 (table and one operator). Contact *Bill Ziegler KA6TYY, 1307 Ashburton Dr., Millersville MD 21108. Tel. (410) 987- 2384 eves.*

FEB 14

ORLANDO, FL The Orlando HamCation Show and Computer Show, ARRL North Florida Convention will be held at Central Florida Fairgrounds, Rt. 50, 3 mi. west of I-4. Sponsored by OARC of Orlando. Setup Fri. 9 AM–5 PM. Open to the public Fri. 5 PM–9 PM, swap tables only. Sat. 9 AM–5 PM; Sun. 9 AM–4 PM. Largest tailgate area in Florida. RV overnite parking $16. Advance tickets $6, $9 at the gate. Free parking. Swap tables $25/Tailgate $15 all 3 days. Forums: NASA Astronaut, Slide/Photo Exhibit of Lightning Storms, ARRL, APRS Demo by Bob Bruninga, WX Downloads, WX Equip. for the Home, Shortwave Listening by Bob Grove, Publ. *Monitoring Times*, Build a VHF SWR Meter, Grounding for Lightning, Antenna Workshop, Radio Testing, DX Speaker Al Hernandez and Ladies' Programs. For info and adv. tickets, contact *Orlando HamCation, P.O. Box 547811, Orlando FL 32854. E-mail: kd4jqr@aol.com. Web Page www.cycat.con/users/oarc.*

PROPAGATION

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

Seasonal lows in solar flux values, combined with the consistently low flux values (60s and low 70s) at the end of Cycle 22 and the beginning of Cycle 23 will *not* bring smiles to the faces of DXers this month. Conditions are expected to be Fair (F) or trending around Fair for many days of the month, but there will be *few* Good (G) days and *many* Poor (P) or Very Poor (VP) days... unfortunately, on weekends also. Geophysical upsets may be expected between the 5th and 7th as well.

10–12 meters

A few possible daytime F2 layer openings to South and Central America on the Good (G) days.

15–17 meters

Fair DX openings on Good (G) days between noon and sunset, and short-skip openings during the daylight hours. The band dies at sunset.

20 meters

DX to most areas of the world during daylight hours, peaking a few hours after sunrise and again during the early afternoon. Although the band usually closes soon after sunset, you may find occasional openings to South America and Antarctica until midnight. Daylight short skip from several hundred to 2,000 miles or so possible on most Good (G) or Fair (F) days.

30 meters

DX toward Europe in the late afternoon and evening on Good (G) days until midnight, and then toward the Orient in the early sunrise hours. Possible long-path DX in the morning and also short skip most days out to a thousand miles or more, and farther in the evening.

40 meters

DX toward Europe and Africa in late afternoon hours, toward South and Central America around sunset, and good openings to the West and South Pacific peaking around sunrise on Good (G) days. Expect daytime short skip to 1,000 miles, and 2,000 miles at night.

80–160 meters

Both are excellent bands for DX during hours of darkness, peaking at midnight and just before dawn. Daytime skip on 160 is nonexistent, but on 80 it can be up to 500 miles, and over 2,000 miles at night. On 160, short skip can reach from 1,000–2,500 miles at night. Experts prefer vertical polarization for transmitting antennas (low-angle signal take-off) and horizontal polarization for receiving antennas (less noise) on 160 meters.

When using the "Time, Band, Country" chart: Where 10 meters is shown, also check 12 meters; where 15 meters is shown, also check 12 meters; where 20 meters is shown, also check 17 meters; where 40 meters is shown, also check 30 meters. The ionosphere is *not* consistent at all times and locations; hence the bands shown are also inconsistent. 73

UPDATES

Continued from page 85

Yagi update

If a parts list seems a bit too small, it just may be.

Here is the list that was omitted from the October issue's "440 Yagi Link Antennas":

Parts List

For each antenna:

1	18" to 20" piece of 1" square aluminum boom stock
1	13-5/8" piece of 3/8" aluminum tubing (reflector)
1	13" piece of 3/8" aluminum tubing (driven element)
1	12-5/8" piece of 3/8" aluminum tubing (first director)
1	12-3/8" piece of 3/8" aluminum tubing (second director)
1	2-1/4" piece of 3/8" OD aluminum tubing
1	3/8" by 3-1/2" piece of thin aluminum sheet stock (for gamma match tube)
1	7/8" by 2-1/2" piece of thin aluminum sheet stock (for SO-239 mount)
6	#6 by 1" self-tapping stainless steel screws (for mounting all parts so far)
2	#4 by 3/8" machine bolts with nuts and washers (for gamma strap)
1	3-1/2" piece of RG-8 coax with outer cover and shield removed (gamma)
1	U clamp (for mounting boom to mast)

NEVER SAY DIE

Wayne Green W2NSD/1

"The Weather Here ......"

When I hear those words I'm pretty sure the chap on the other end is going to be a dud contact. I don't give a rat's rump what his weather is unless there's been a tornado or something really worth talking about. And I honestly don't care what commercial rig he was able to afford, so none of that "The rig here is..." stuff either. That, too, tells me that he hasn't given any thought about what might be of interest to me, that I am just another formula contact for him. Gee, maybe he "needs" a NH QSL. Wowie, oh thrill! That's worth 32¢ for me anytime, plus filling out the card and looking up his address in the *Callbook*. Sure.

When you call me I want to know something about you, not what kind of an antenna or what rig you bought. One of the reasons I wander off ham radio in my editorials is my obviously wasted effort to get you to at least ask someone you're talking with if they've read my latest crazy editorial. And I recommend books which would give you endless things to talk about, if only I could get you to read them. Sigh.

Yes, I'll send you a confounded QSL. Oh yes, and roger on your rig, your antenna, your weather, and the serial number on your mike. But are you active on packet, satellites, the Internet? Have you worked any interesting DX lately, maybe even been somewhere interesting? What do you think about the possible (maybe probable, considering the ARRL's undiplomatic actions) loss of 2 meters? *Talk* to me!

Boilerplate

While I was at it I also put together a collection of 43 of my ham-oriented editorials for ham club newsletter editors to use as filler when their club members fail to provide enough fodder. Those small filler items in newspapers are called boilerplate.

I get around 50 club newsletters every month and while some are packed with interesting stories, others are awfully dull. Since only about 20% of the hams read *73*, it seemed to me that my editorials would be new for most newsletter readers, and could use some repetition for the others. And no snide remarks about my own repetition, please.

Any newsletter editor interested in getting some interesting filler can send me a copy of the newsletter and I'll send a *Boilerplate* book. Yes, I can dump any desired segments to disk, if that'll help. Mac Word format. If you just have a morbid interest in my past ham-oriented editorials the collection is $5. A steal.

Shocking

A newspaper article from Graham Rogers VK6RO cites another medical anomaly worth investigating. This has to do with a chap who was suffering from Ross River virus, which produces extreme fatigue and lasts a year or two. It's transmitted by mosquitoes. It seems this chap who was suffering from the virus had difficulty even getting out of bed. Then he accidentally got pushed into an electric fence and got a dandy shock. The next day he had recovered from the virus. He told a good friend of his who also was suffering from the virus about it. The friend came around and zapped himself on the fence and within 15 minutes his pains were gone.

Some time ago I wrote about the Amazon Indian cure for snake bite where they take the wire off their outboard motor spark plug and zap the bite to counteract the venom. Indeed, the jungle aviation flyers take along a spark coil system in their planes just for that emergency.

This ties right in with the letter from KA1UMW ("Letters") and his experiences.

Now, I suppose you're going to ask me why the medical industry is blind to these anomalies. How can they pass up researching electrical approaches to curing illnesses? You wouldn't ask that if you'd read the exposé books on the industry on my recommended list. The big money in the $1.5 trillion American medical industry is in selling medications. If the drug companies can't develop and patent a pharmaceutical which will bring in hundreds of millions, you aren't going to see it. Or have you bought any pills lately? And the pill and shot pushers are solidly backed up by the AMA, the FDA, and on down the list, complete with swat teams to put you in prison if you try to cause any trouble. Lordy, you should see some of the letters I've been getting from FDA prisoners around the country!

Perhaps you can understand why I'm so enthusiastic about the Beck blood purifier and Bioelectrifier (May issue).

Memorial

What do you want to be remembered for? If you ask a kid this he won't have an answer. It isn't until you're along in your 40s or so that you begin to understand what this means. We can't all leave great music or art behind as a memorial. Or even one stone in a great wall somewhere. So I sit here at my computer, listening to Gottschalk's incredibly beautiful music, goading you to help pioneer any of the endless frontiers of science which are wide open for exploration. Goading you to produce and raise the very best children you can. Goading you to help fix our schools, our health care system, and all the other things you've let our beloved Congress and president, solidly backed up by millions of bureaucrats, screw up. Will your memorial be a work of art? A book? A discovery? A lifetime score of 370 countries worked? Or perhaps a bunch of certificates for winning contests which will eventually get thrown out with those old boxes of QSL cards by your widow? Or just a weathering stone in a cemetery somewhere?

It doesn't take a lot of money to pioneer. Mostly it takes determination.

Speaking of bureaucrats, here's a quote I like: "A bureaucrat is the most despicable of men, though he is needed as vultures are needed, but one hardly admires vultures whom bureaucrats strangely resemble. I have yet to meet a bureaucrat who was not petty, dull, almost witless, crafty, or stupid, an oppressor or a thief, a holder of a little authority in which he delights, as a boy delights in possessing a vicious dog. Who can trust such creatures?" Cicero, circa 50 BC. Who says we haven't made progress in 2,000 years?

There's a whole world of mystery out there, waiting to be unraveled. Pick any thread and see where it takes you.

Congratulations!

Paul Harvey mentioned that our total taxes are now an average of 50.4% of our earnings, setting a new record. This is truly remarkable because in most other countries the people have revolted when the taxes got over 33%. So you are to be congratulated on your ability to get thoroughly screwed and yet keep on cheerfully smiling and re-electing your screwers.

Yes, it's sure nice to have our social security payments when we get old. Of course, if the same money had been invested privately we'd be getting over three times as much back. And the system wouldn't be looking at bankruptcy in a few more years. Sure, it's nice to have Medicare too. And never mind that if the government would let us invest our pre-tax earnings in health care insurance we'd get much better care at less than a

Continued on page 31

LETTERS

From the Ham Shack

Mike Zane K6URI. Late last year I wrote to you commenting on an editorial and mentioning our school ham radio club. You asked for information and photos. Here's the story.

First I contacted all the high school, junior high and elementary schools in our district to see if I could generate any interest in starting ham radio clubs. The three high schools, three junior highs and all but one elementary school were not interested. The only elementary school principal who was interested was one that my wife had taught for previously.

We started out in January 1992 in a portable classroom that was being used as a library. I drove my truck near the front door so we could use the mobile antenna with a portable rig set up in the room. This was not an ideal setup, but at least we could make local contacts. This got some students interested. We now have a locked cabinet on the stage of the auditorium/cafeteria.

We meet only one day a week for one hour after school. Some school terms I have eight to 10 students, and sometimes only three to five. Our school district is so overcrowded that the students are on a three-track system: on four months and off two months. Most of the kids do not come on their off-track time.

It took almost four months for the administration (not the principal) to give their "permission" to start the club. The only requirements were these: The kids had to have a ride home after school (those who were bused); the club was at *no cost* to the district or school; and I couldn't electrocute any of the kids. So far, we have met all three requirements. Through equipment donations, money for study books from our local adult city club, and my junk box, we have a pretty good setup. The station has an MFJ-1270c TNC, a Kenwood 10W TR-7600a, Kenwood TS-520s, Swan SWR/wattmeter, and a 386DX-40 computer. On the roof of the auditorium we have a 2m antenna and a 20/40m trap dipole.

Recently my wife Kristy KE6IQL got her Technician license and we decided to try to start another club at the elementary school where she teaches sixth grade. We got the principal to let us put a packet station in the classroom as a test. So, when she returns to school from off track, we will give it a go.

Our club at Nichols Elementary starts the kids out with some electricity experiments and then they build a basic crystal radio. The next item is a Morse code key, followed by a two-transistor code oscillator. Then the crystal radio is converted to a one-transistor AM radio, and a small audio amplifier is added. By the way, our club has students from grades four through six. Hopefully at the end of October, when my wife goes back on track, we will have another club going and good news to report. I would like to be able to have the club members at both schools get on ATV, which might generate some more interest.

Members of K6URI's elementary school club working on their crystal radios.

Harry Goldman, Tesla Coil Builders Assn. Does Bernard Finn have a problem? ("Letters," August 1996.) Mention Nikola Tesla and he gives a list of also rans. I call it the "Oh but..." syndrome. That is, you credit a person for his contributions to science and Finn comes up with the "Oh buts..." This game can be applied to anyone, Bell and the telephone, for example, as well as Edison for the incandescent lamp and the phonograph. It is no secret that there were others on their trail. And that's the crux of the argument—they were trailing and not leading. Surely Mr. Finn is aware of the fact that the Tesla polyphase patents were dragged through the courts. Although the courts considered the efforts of others, including those named by Finn, Tesla's patents were upheld in every case. When Niagara went on line in 1896, the famous Lord Kelvin declared that "Tesla had contributed more to electrical science than any man up to his time." Whew, that takes in a bunch of highly respected names.

I agree with Mr. Finn that Edison's incandescent lamp established a need for a source of electricity. But there were single-phase AC systems available at the time. Why, then, did so many years pass between the birth of the incandescent lamp and Niagara hydroelectric power? It is no coincidence that Niagara hydroelectric came into existence shortly after the appearance of Tesla's patents.

Much of the discussion above can be applied to the wireless telegraphy controversy. By 1893 Tesla had developed the principle of the four-circuit system of communications. The idea employed inductive coupling between the driving and working circuit, the importance of tuning both circuits, the idea of an oscillation transformer, the capacitance loaded open secondary, and tuned antenna circuits grounded at one end. Again, I agree with Mr. Finn that there were others who later applied their own innovative ideas. But they would have gotten nowhere without employing the above named components. The way to wireless telegraphy was through Tesla.

Tesla's contributions to wireless telegraphy did not go unnoticed by his peers. Tesla was hailed as the "father" of wireless telegraphy by L.W. Austin (leading U.S. Government radio expert), M.E. Giradeau (pioneer in French communications), A. Slaby (whose work helped to establish the Telefunken system in Germany), A. Popov (often referred to as the Russian Marconi), as well as by others. E.H. Armstrong (FM and advanced radio circuits) praised Tesla for his visionary work in wireless and credited Tesla as the originator of radio control systems. John S. Stone (named in the U.S. Supreme Court decision) stated that "Tesla was so far ahead of his time that the best of us mistook him for a dreamer."

With numerous awards, 15 honorary doctorates, a unit of measurement bearing his name, an IEEE annual award presented in his honor, and so on, it is difficult to understand why the Smithsonian can ignore Tesla's accomplishments.

The lack of artifacts is given as one reason. That situation did not stop MGM when it was preparing for the 1940 film "Edison, the Man." The studio sent its craftsmen to museums with Edison holdings to take photographs and make measurements. It took only six weeks to replicate Edison's most important inventions, and that includes the Pearl Street generating station. These were not Hollywood props but 1:1 scale working models! Tesla artifacts are in abundance at the Tesla Museum in Belgrade. I am confident that the Smithsonian crafts department is just as capable as MGM's.

Even if artifacts are lacking, the Smithsonian has numerous papers on Tesla's work that have been donated by engineers and historians. Why hasn't the Smithsonian used them to publish a monograph on Tesla?

And in conclusion, I might as well mention my own personal complaint. In 1994, a friend stated that he saw a portrait of Tesla at

the Smithsonian. Thinking that it might be something I do not already have, I sent a request for information. Two years have passed without a satisfactory reply even though I have sent reminders on two subsequent occasions.

The situation is a disgrace—another example of politics messing things up... Wayne.

Raymond Bergeron KA1UMW. When I was less than 12, I saw a little German chiropractor (Dr. Leonard A. Kaam) for relief from bronchitis symptoms, for an injury from a tree fall, and for Osgood Slatter's disease. This chiropractor had a "little black box" that ran on batteries. I would hold a solid brass probe in one hand while he probed the affected area with the other. He had a small figurine of the human body that was covered with numbers. When he wanted to treat my ailment or symptom (stuffed-up sinuses, for example), he would look up sinuses in a book. The book would give him a list of numbers which he would find on the figurine. He said that the numbers were nerve ending points. Using his probe, he would touch the area of my body as indicated by the numbers. A tone would come from the box and get louder as he approached the nerve ending (presumably by finding the least resistance). When the tone was the highest in pitch he would push a button on the probe and a series of electric pulses would run through me (they would often be a little painful) for about five seconds. After a few of these hits (around the nose for the sinus treatment), I would feel the dams bursting and my sinuses would be instantly clear, with the gunk running down the back of my throat. He would always tell me that his box could cure anything, clear up a blocked artery, etc. He even said if I ever had a heart attack or a stroke, not to go to the hospital but to go see him and he would clear it up instantly.

Well, he also had another gray box called a Century Mach IV Galvanic Stimulizer. This little device had a big pad that was soaked in warm water and placed on your back, and two smaller wet pads that are placed on the injured area. The machine would run an AC current through your body. The current was variable from nothing to painful, at a frequency from 30 to 120 Hz. The current would switch from Pad A to Pad B, going to the big common pad on your back at a rate of 2.5, 5, or 10 seconds. Well, as a late teen- and early 20-ager I started to service these little gray machines, which reportedly cost $5,000. My chiropractor managed to get a schematic for me so I could repair them. The unit was just a simple 36-volt pulsed variable-current generator, with a timer—sound familiar?

If you have any chiropractor friends ask them about the physics involved and it may help with the plant growth stimulator.

Hmm, is this another lost technology? Seems worthwhile investigating. Were those "nerve endings" actually acupuncture points? Maybe some of those fancy electrical gadgets of long ago which the "modern" medical industry ridicules actually did work! Of course, if your pioneering spirit has been totally decimated, then never mind. And for heaven's sake don't read the Robert Becker books... Wayne.

Mike Truax KB9OCE. Wayne, you recently asked to hear about Elmers, so I thought I would tell you about my Elmer: my brother Jerry Truax N3SEI. I first became interested in amateur radio 22 years ago. My main interest then, as it is now, was HF. I have an HW-9 that I built in the late eighties which has yet to go on the air. Every time I was ready to take the test, I either couldn't find the time and place of a test, or I was working. Finally, in June this year, after calling off from work, I took the test. I had originally planned on going for Tech+. However, when the VEs told me that I had only missed two on the entire exam, I was so excited that I knew I'd never be able to concentrate on the code. I raced home to call my brother with the good news. His encouragement (and stubbornness) had finally paid off. A few days later I received a package from him. He had sent me a 2m HT so that I could get on the air as soon as my license arrived! There was one string attached. Now I have to become an Elmer, and the first one that I Elmer gets the HT upon passing the exam... with the same string attached. That's a new twist on "incentive licensing" for sure!

I now have to study for the General. I wish I had done this years ago. Most of the blame is my own; however, for the general public, VE exams are one of the best-kept secrets around. I really think that our ranks would grow faster (and stronger) if more people knew about them. Our local Radio Shack™ knew nothing about local amateur radio activities, other than what I relayed to them. Most newspapers have a "community bulletin board" column. The newspapers can't print dates for VE exams or local club meetings, etc., if they don't know about them. The best part is that this is *free* advertising!

I suggest coverage of activities like Skywarn, Field Day, hamfests; the list goes on. I would really love to see an article about Bill KA9ONS, one of our local amateurs who normally runs our Weathernet. Bill and the guys do such a fantastic job. They too are part of the reason that I finally took time to get licensed. Hmmm, since I am a free-lance writer, maybe I'll write the article—after all, if we don't promote ourselves, nobody else will! Maybe our local club (and yours) could use a Publicity Chairman. Volunteer! Remember the old saying: "Volunteers can't be bought; they're priceless." It's true! Don't worry, Wayne, I have a few articles in the works for you that I will be sending as soon as my research is complete. We could trade my work for back issues of *73*. After all, they don't call you Never Spend a Dollar for nothing.

I would like to thank not only my brother Jerry N3SEI, but also you, Wayne, for the encouragement through your editorials (yes, somebody *was* listening!), Gordon West for his excellent study materials, our local Skywarn Weathernet, and our local VEs—John KF9YS, Mike WT9W, and Stan KD9BE—for giving up their valuable time so that a 22-year dream could become reality. Each and every one of you is my Elmer in your own way, and you

QRR . . .

Number 8 on your Feedback card

Scholarships for Licensed Hams

The Foundation for Amateur Radio, Inc., a nonprofit organization with headquarters in Washington D.C., plans to administer 60 scholarships for the academic year 1997-1998 to assist licensed radio amateurs. The Foundation, composed of over 75 local area amateur radio clubs, fully funds five of these scholarships with the income from grants and its annual Hamfest. The remaining 55 are administered by the Foundation without cost to the various donors.

Licensed radio amateurs may compete for these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled in or have been accepted for enrollment at an accredited university, college or technical school. The awards range from $500 to $2,500, with preference given in some cases to residents of specified geographical areas or the pursuit of certain study programs. Clubs, especially those in Delaware, Florida, Maine, Maryland, New Jersey, Ohio, Pennsylvania, Texas, Virginia, and Wisconsin, are encouraged to announce these opportunities at their meetings, in their club newsletters, during training classes, on their nets and on the World Wide Web home pages.

Additional information and an application form may be requested by letter or QSL card, postmarked prior to April 30, 1997, from:

FAR Scholarships
6903 Rhode Island Avenue
College Park MD 20740

The Foundation for Amateur Radio, incorporated in the District of Columbia, is an exempt organization under Section 501(C)(3) of the Internal Revenue Code of 1954. It is devoted exclusively to promoting the interests of amateur radio and those scientific, literary and educational pursuits that advance the purposes of the Amateur Radio Service.

73's "Survey" Winner

The winner of $100 plus a lifetime subscription to *73* is Harry Longerich of Fredericksburg, TX. Congratulations, Harry, and thank you for participating in the "Survey" in *73's* November issue.

Cities Will Challenge FCC

Look for major court challenges by city planners, community managers, and homeowners' associations to recent rulings by the FCC—rulings that forbid states, cities, municipalities, homeowners' associations, and even individual landlords from enacting rules preventing the installation of those pizza-sized satellite TV dishes.

When it used its power and preempted local jurisdiction and land use regulations to permit anyone to install one of the mini satellite antennas, the FCC said it was doing so to ensure that the general public had access to the latest in television transmission technology.

But according to recent news reports, some cities, states, and many homeowners' organizations disagree. A spokesman for a coalition of urban planning groups say that the federal government has no right to dictate the aesthetic look of a community; that controlling satellite dishes and any antenna structures must be done on a community planning level.

With both sides now having their views cast in concrete, it will be up to the legal system to decide who has the final word. Urban planners say that they will be going to court in an all-or-nothing effort to wrestle the power of federal preemption away from the FCC. While it will be many years before any final determination is made, whatever the outcome, the future of many radio services that use visible antennas—including amateur radio—may well hang in the balance.

Adapted from an editorial in the *"marcKey,"* official newsletter of the Manteca ARC, November 1996.

Ham's Best Friend

...like man's in general, is the dog. Why?

10. He doesn't need a chair.
9. He always answers your call.
8. He entertains you when the bands are dead.
7. He keeps your feet warm on cold winter nights.
6. He never reminds you how late it is.
5. He understands your frustration; he's been in a few dogfights himself.
4. He doesn't talk while you're trying to copy code.
3. He's one being whose CW skills are worse than yours.
2. He doesn't care how much you spend on QRP gear.
1. He listens before he barks.

By Steve Burel AD4LY (lifted from the *"ARNS Bulletin,"* December 1996, which lifted it from the Colorado QRP Club's official newsletter, *"The Low Down."*)

FCC Enacts Morse Code Requirement on Internet Access

(Note for the humor-impaired: This is satire. Please do not read this if you are not properly trained and certified in satire.)

The FCC, under pressure to clean up the Internet, especially after the Communications Decency Act provisions regarding Internet content were stricken as violating the U. S. Constitution, has decided instead to enact a Morse code proficiency requirement for Internet users. Citing the success of the Amateur Radio Service and the general belief that its requirement to operators to pass a Morse code proficiency exam, and other technical requirements, has kept the ARS "clean," the FCC will enact a 5 word-per-minute requirement for all Internet users. They are leaving open the issue of whether there should be a "codeless" class of Internet user and are soliciting comments for proposed rule making on this proposal.

Persons wishing to develop a web site having only links to other web sites which in turn have only links to other web sites, and so forth, must pass a 13 word-per-minute Morse code test and demonstrate proficiency in HTML, the Internet authoring language.

Persons who wish to develop web sites that have actual content, as compared to just links to other web sites, must pass a 20 word-per-minute Morse proficiency test, demonstrate proficiency in HTML and the Java programming language, and show that they have mastery of at least one human language, such as English.

The FCC, which lacks budgetary authority to implement the testing program, has stated that it intends to create a Volunteer Examiner Program to test Internet applicants.

Swiped in its entirety from Clear Lake ARC's *"Radio Amateur Gazette,"* October/November 1996.

Tucker Out of Ham Biz

Tucker Electronics Company, a distributor of new and reconditioned electronic test and measurement equipment, amateur and shortwave radios, and electronic hobbyist products, has announced the sale of all its ham radio-related assets (including the recently acquired Oklahoma Comm Center) to Ham Radio Outlet.

Tucker Electronics has discontinued operations of its retail store in Dallas and its consumer mail-order business; the toll-free ordering number is being serviced through HRO's New Hampshire store. At last report, Tucker is marketing its vintage radios and any inventory not acquired by HRO on its web site (www.tucker.com).

The sale of its amateur radio business will allow Tucker Electronics to focus on its core business, distributing new and reconditioned electronic test and measurement equipment.

Nautical Smiles

The following transcript of a radio conversation between a US Navy ship and a Canadian source off the coast of Newfoundland was released by the Chief of Naval Operations on Oct. 10:

US Ship: Please divert your course 15 degrees to the north to avoid a collision.

Canadian: Recommend you divert YOUR course 15 degrees.

US Ship: This is the captain of a US Navy ship. I say again, divert your course.

Canadian: No, I say again, divert YOUR course.

US Ship: This is an aircraft carrier of the US Navy. We are a large warship. Divert your course now!

Canadian: This is a lighthouse. Your call...

Amateur Radio and Linux

Software home-brewing is here!

Richard Parry W9IF
13842 Deergrass Court
Poway CA 92064-2276

October 5, 1991: "Do you pine for the nice days of Minix-1.1, when men were men and wrote their own device drivers? Are you without a nice project and just dying to cut your teeth on an OS you can try to modify for your needs? Are you finding it frustrating when everything works on Minix? No more all-nighters to get a nifty program working? Then this post might be just for you."

With that simple introduction, Linus Torvalds, a Finnish graduate student, announced to the world Version 0.02 of Linux on the USENET newsgroup comp.os.minix. Linux is pronounced "Lean-nucks," based on the Finnish pronunciation of Linus. Linux is a perfect platform for software development for amateur radio. It offers a plethora of freely distributed high quality software and a knowledgeable and helpful community of people (very much like the amateur radio community) ready, willing, and able to help; kind of like a ham's "Elmer." Although credit for the original idea for Linux must go to Linus Torvalds, the kernel and copious other software are the result of an international collaboration of dedicated people.

No doubt the gamut of readers of this article range from those who use Linux on a daily basis at work and/or home to those who have never heard of it. For those who fall into the latter category, Linux is a 32-bit, multi-tasking, multi-user, freely distributed UNIX-like operating system. Technically, Linux is only the kernel or core of the operating system; however, in general it represents all the software that normally comes with a complete distribution. Platforms upon which Linux runs include: DEC Alpha, Commodore AMIGA, Sun Sparc, MIPS, Atari ST, and Apple Macintosh. However, without a doubt, the 386, 486, and Pentium based systems are the most popular. Linux is not copyrighted and there is no AT&T code included (UNIX was born at AT&T). Linux is licensed under the Free Software Foundation's General Public License which specifies, among other things, that the source code must be freely available. It is the inclusion of the source code that is perhaps most unique. If you ever wondered how an operating system, network, compiler, assembler, or editor works, it is all there for you to study and modify to your heart's content.

There was a time when most ham radio operators built all or part of their amateur radio stations. I have built my share of transmitters, electronic keyers, RTTY widgets, antennas and more. The desire to build was based on the thrill of learning and building. In fact, I remember taking months to build a nifty gadget for the shack, using it for a week to see if it worked, and then returning to thinking of something else to build. I believe most of the amateur radio community feels the same way. However, home-brewing now includes software, and for that development Linux is the perfect platform.

"Where else but with Linux can you get the complete source code for a C++ compiler, an operating system, and the support of hundreds of thousands of users worldwide?"

Who is it for?

At the PACIFICON conference Bruce Perens AB6YM commented, "There's a saying that marketing people have about programmers: 'Leave a programmer alone, and he'll come up with the kind of product that only a programmer could love.' That's what UNIX is, and Linux too. Actually, other kinds of propeller-heads such as hardware designers, mathematicians, etc. have been known to be comfortable with UNIX and Linux. But why use an operating system that only a nerd could love? Well, you want them to write more software, don't you? UNIX and Linux are the most comfortable platforms for the development of sophisticated software that communicates, controls hardware, does complicated math ... what I'm trying to say is that it's the best platform for developing the kinds of software that radio amateurs need."

Who is Linux for? "Not for everyone" is the simple answer. Linux and UNIX are industrial grade operating systems. They both support a wide variety of GUIs (Graphical User Interfaces), but they are predominately a CLI (Command Line Interface). They are powerful, but with power and flexibility comes some complexity. Matt Welsh begins his book (see references) with, "Before you looms one of the most complex and utterly intimidating systems ever written: Linux, the free UNIX clone for the personal computer, produced by a mish-mash team of UNIX gurus, hackers, and

10 Ways to Tell if Linux is for You
1. You don't own *DOS for DUMMIES.*
2. You don't hate typing.
3. You don't mind reading manuals.
4. You don't like going to bed before midnight.
5. You don't own *Internet for Idiots.*
6. You do like learning.
7. You do like challenges.
8. You do like to build.
9. You do like to experiment.
10. You can stop the VCR from blinking 12:00.

Table 1. *A humorous checklist to aid you in making the decision to use Linux. However, as with all humor, there is always an element of truth.*

the occasional loon. The system itself reflects this complex heritage, and although the development of Linux may appear to be a disorganized volunteer effort, the system is powerful, fast, and free. It is a true 32-bit operating system solution."

If Matt's introduction has not scared you, then a more humorous test to see if you are ready for Linux is included in **Table 1**. Since you probably already have the hardware, a personal computer, and Linux is free, you have nothing to lose and a whole lot to gain. UNIX and Linux experience on a resume never hurt anyone!

What's available?

Just about everything you can imagine for serious software development is available for Linux. But that is only part of the story. The fact that it all comes with the source code and the enthusiastic support of authors and users worldwide means you can probably get an answer to your question within hours, and that includes 3 a.m. Much of the documentation for Linux comes from the Linux Documentation Project (LDP) in the form of HOWTOs. These documents typically range from 10 to 50 pages and provide in-depth information on a particular subject. There are currently 50+ HOWTOs to aid the user with Ethernet, XFree86, sound, video, networking, and more. For the amateur radio community, there are two in particular, a HAM and AX.25 HOWTO. **Table 2** is based on the HAM HOWTO and includes a summary of the software available for amateur radio. This document and other HOWTOs can be obtained from: http://sunsite.unc.edu/mdw/HOWTO and other mirror sites.

However, the purpose of this article and of Linux is not to get you started assembling a computer system based completely on applications that you can download; it is to inform the amateur radio community of an operating system (OS) that is an experimenter's dream. Here is your chance to learn C, C++, Perl, awk, Smalltalk, Tcl/Tk, FORTRAN, Python, shell scripts, networking, real-time systems, and more. It is a chance to put together a TCP/IP packet network that cannot be duplicated on any other platform. The reason for this is that the packet radio protocol is now built right into the kernel. Linux is the only operating system in the world that can boast standard and native support for amateur radio protocols. In fact, packet radio uses the same interface as the Internet. Therefore, any program which you use on the Internet can also be used as a packet radio program. For example, your favorite Internet programs such as Netscape, Mosaic, telnet, and ftp will work and not care, or know, that the medium they are using is packet radio.

Getting started

Table 3 shows the hardware for a comfortable system upon which to install Linux. I want to emphasize the word "comfortable," since you can get away with a lot less, especially hard drive space. However, most of you are not going to give up DOS or Windows 3.x right away (this might eventually happen, however) so you will want to make a partition on the hard disk for your DOS environment and another for Linux. One of the great benefits of Linux is that you don't have to give up anything you currently use. If you fear that Linux means leaving your current OS behind, fear not, Linux offers emulations for DOS, SVR3 UNIX, SVR4 UNIX, Macintosh and even older computers such as the Apple II and Commodore 64. For those of you who like GUIs, Linux has many to choose from. There are several versions of X Windows, including: twm, fvwm, and

CD-ROM (any speed, SCSI, IDE, etc.).
Video card supported by Linux.
Mouse (3-button type preferred).

***Table 3.** Linux runs on many platforms; however, for most hams the platform of choice is the PC. Shown here is a good hardware configuration for Linux software development.*

others. X Windows is a very powerful interface which allows great configuration flexibility.

Regarding file formats, as you survey the various distributions you will come across the terms "a.out" and "ELF" (Executable and Linking Format). Both are binary formats, the former being used for many years but now falling into disuse due to the advantages of ELF. The Linux community supports both formats during the current transition period. All of the distributions listed in **Table 4** support ELF.

During the installation of Linux you will be asked questions about your system's hardware configuration. Chances are you are using standard port assignments and addresses and the installation will go smoothly, but you should have your documentation handy just in case. For example, you might need to know your serial and parallel ports' I/O memory locations, and the IRQ (interrupt) addresses for devices (e.g., serial ports, sound cards, SCSI ports, video card, etc.). If you are not sure, most of the scripts have a default value to suggest, and in most cases you can't go too far astray sticking to the defaults in lieu of firsthand knowledge. Unless you have done

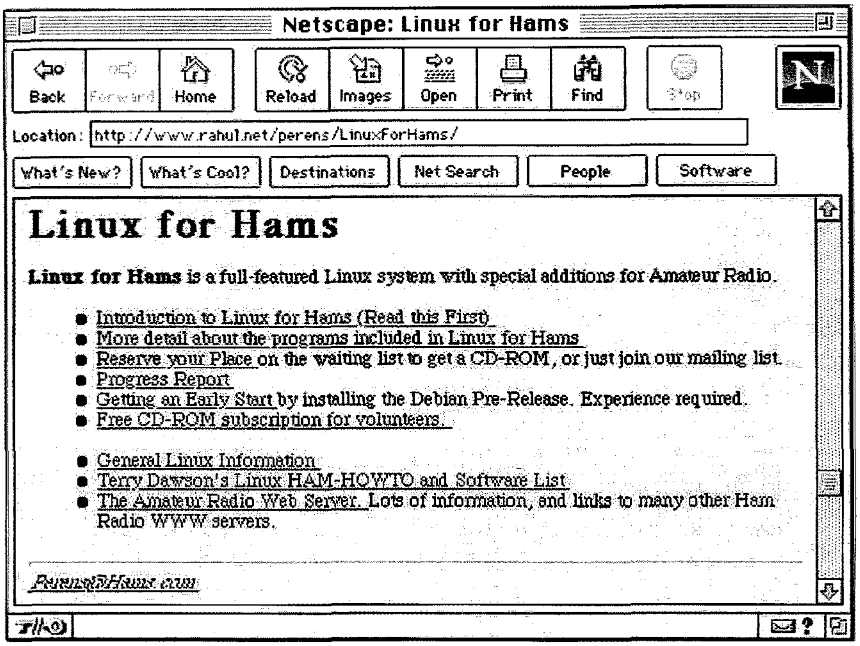

Fig. 1. The Linux for Hams homepage maintained by Bruce Perens AB6YM. Available at: http://www.rahul.net/persens/LinuxForHams/.

something strange with your hardware configuration, the defaults should work fine.

Although I said that everything for Linux is free and can be downloaded from the Internet, I would not advise that for anyone, even a UNIX guru. A small Linux installation can consist of a thousand or more files easily consuming 50+ MB of space. A complete installation which includes source code, copious documentation, computer languages and examples, and the X Window system can easily take up much more (e.g. 500+ MB). For this reason downloading is not practical. Fortunately, there are many CD-ROM publishers who include a complete distribution of Linux along with excellent installation software.

There is a lot more to Linux than the kernel. There are editors, compilers, linkers, assemblers, and utilities, to name a few items. In fact, in most distributions you will get several of each. For example, I have at least six different editors, although I use only one (emacs). For this reason it is not unusual for a distribution to consist of two or three CD-ROMs. In fact, Matt Welsh's book (see references) can be purchased separately or with a 5 CD-ROM Linux distribution. The prices for all of the distributions are reasonable and they are well worth it.

Another reason for using CD-ROMs is to take advantage of the "installation scripts" that accompany the distributions, some of which provide a graphical user interface. These installation scripts will walk you through the installation process, asking you questions about your system. Don't worry that you will be shielded from knowing exactly what is going on during the installation—there will be plenty of time for you to explore Linux later.

Another source for information is your local bookstore. Go to the computer section and chances are you will be surprised at the number of books devoted to Linux. I counted over a dozen during a recent visit, and there are many more that can help you during installation, configuration, networking, and more.

Last, and certainly not least, the World Wide Web is a great source of information. I have included a list of key web sites to visit in the references. Of particular interest to amateur radio operators is Bruce Perens' Linux for Hams homepage, shown in **Fig. 1**.

Figs. 2 and **3** illustrate two of the many other features of interest to ham radio operators. **Fig. 2** shows one of the SatTrack windows written by Manfred Bester DL5KR. SatTrack is a satellite orbit prediction and real-time tracking program with X Window System color graphics displays. It has been written in the C language and runs on UNIX and Linux systems, using only basic X11 and X11 Toolkit functions for the graphics displays. The program not only displays in real-time where a number of satellites are, but is also capable of controlling suitable ground station equipment, like

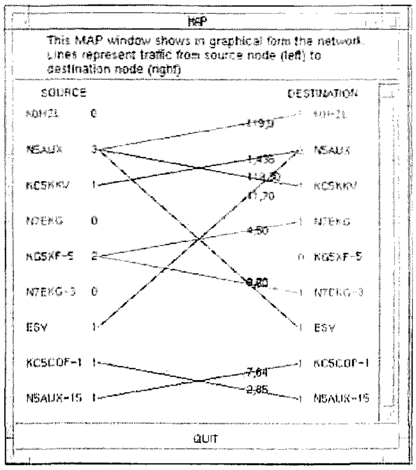

Fig. 3. A MAP window from XNET, a network analyzer designed specifically to monitor AX.25 packet radio networks.

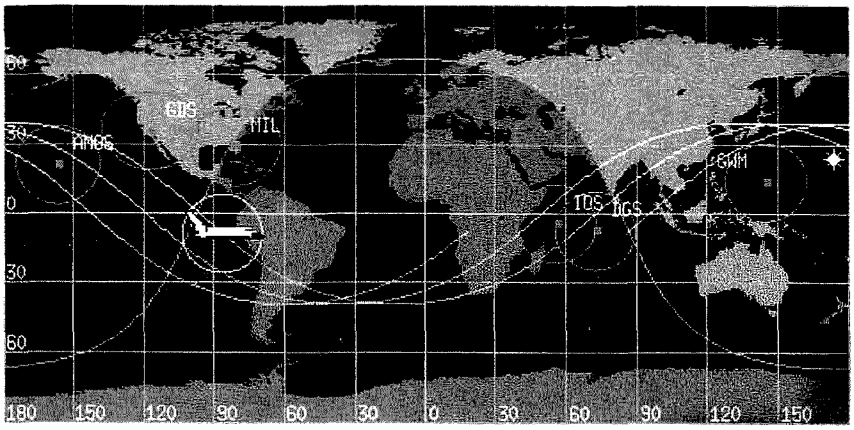

Fig. 2. A SatTrack window written by Manfred Bester DL5KR.

antennas or optical telescopes, radio communications hardware or other sensors. An autotrack mode can track any number of satellites and switches automatically between them as they rise and set. Predictions of passes of satellites over specified ground stations can be run off, either interactively or in batch mode. The page is located at: http://www.primenet.com/~bester/bts.html.

Fig. 3 shows a window from XNET, written by Richard Parry W9IF. This is a network analyzer designed specifically to monitor AX.25 packet radio networks. It will collect and display network data, allowing the user to understand network traffic and channel utilization. XNET was written in

"Linux offers a chance to put together a TCP/IP packet network that cannot be duplicated on any other platform—the packet radio protocol is now built right into the kernel."

Tcl/Tk and provides many features that are useful to both the casual packet user and the packet radio BBS sysop wishing to better understand the network. The XNET homepage is: http://www.qualcomm.com/~rparry/xnet.html.

Conclusion

Almost every amateur radio operator has been asked, "What is amateur radio?" There are a variety of answers and none are incorrect. For me, amateur radio is the thrill and excitement of experimentation, with both software and hardware.

If you need to write a letter, do your taxes or develop a spreadsheet, there are computer systems that do that, and do it very well. They give you the power to be your best and concentrate on the task at hand. For software development, however, you can't beat Linux. Where else can you get the complete source code for a C++ compiler, an operating system, and the support of hundreds of thousands of users worldwide?

Elegant Rotating—Revisited

An enhanced beam-aiming circuit.

Chet Garrison W6ZZB
3544 E. Dayton Ave.
Fresno CA 93726

A year or so ago, I was browsing through older issues of *73* and I came across an article titled "Elegant Rotating," by L. B. Cebic W4RNL (*73*, June 1984). His article dealt with an earlier beam-aiming circuit by K9AZG (*73*, November 1982), and offered some interesting improvements. The circuit is used to control CDE and similar rotor control boxes so that by setting a single potentiometer you can sit back and wait while the beam is aimed at the desired setting and stops, automatically.

I don't know why I ignored the article at that time, but when I read the article again I decided to build it for myself because my rotor was of the CDE variety.

I put the circuit together using point-to-point wiring and perfboard, and it worked beautifully! Because it was ugly, I hid it in a cabinet with a nice-looking front panel before I began using it.

Since then my oldest son has become licensed (KC6JAI). He and my friend W6BJI asked me to build an aimer circuit for each of them. One had a CDE, the other a "tail twister" rotor.

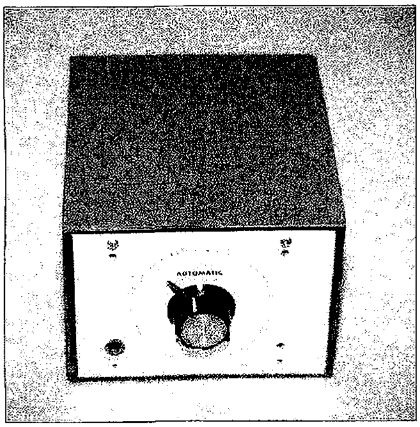

Photo A. One of the partially-completed beam-aimers.

In the meantime I had obtained a computer-aided design (CAD) program so I set out to make a circuit board for the aimer, and it was successful. (It wasn't easy, but the results were very gratifying.)

Before submitting this article to *73*, I contacted W4RNL and asked for permission to use information, including circuit diagrams, from his article. He replied and said OK, but also suggested I include some sort of audible device to help sightless operators, hence the little circuit added to the power supply board. Rotating the beam in CW direction produces a tone of one frequency, while rotating in the other direction produces a different tone (more about this later).

I'm very happy with the results and have since replaced the original effort with a newer, and much neater, circuit. With this circuit I can rotate my beam a full 360 degrees, stopping anywhere I want.

The circuit

I don't feel that it is necessary to go into K4RNL's article all that much. I refer anyone wanting to build this

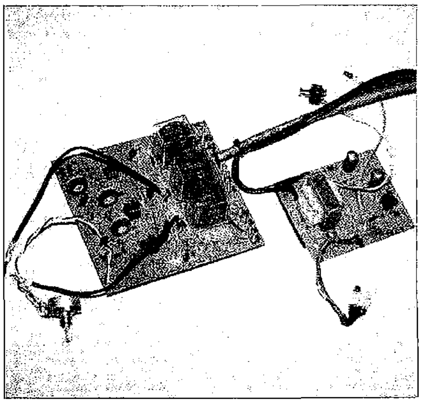

Photo B. The main aimer board and the separate power supply board.

rotator control circuit who feels the need for some theoretical information to the article in the June 1984 issue of *73*.

Instead, I have only included K4RNL's circuit diagram, **Fig. 1**. Please note the following correction to his original circuit: The top normally-closed contact of K1 is *not* connected to the top normally-closed contact of K2. The upper moving contacts of both K1 and K2 *are* connected to terminal #2 (common).

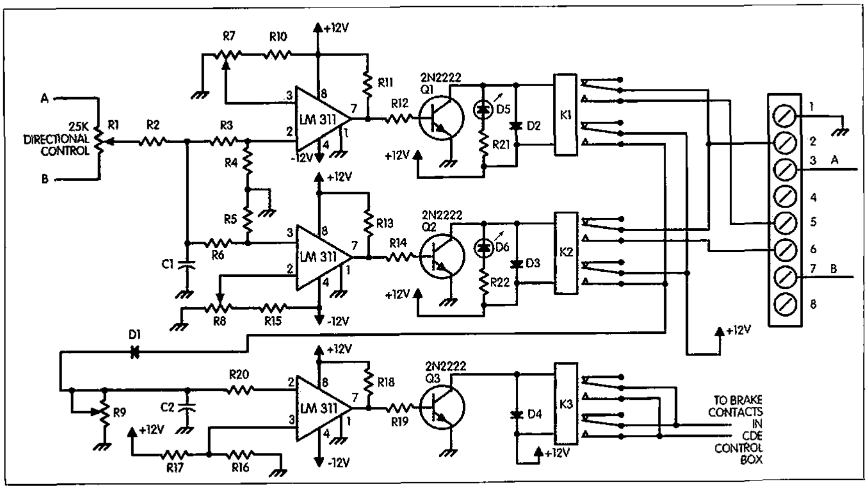

Fig. 1. K4RNL's original circuit diagram.

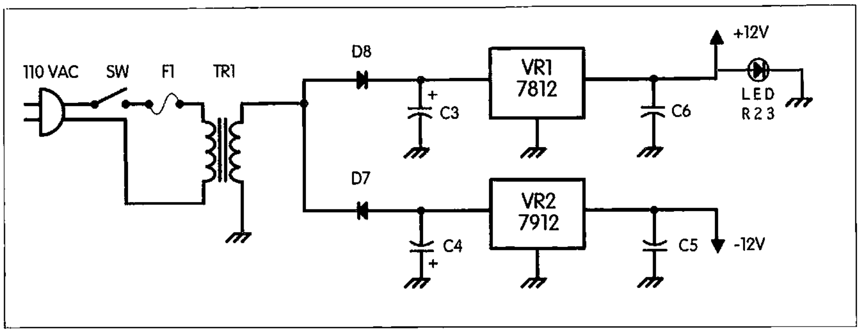

Fig. 2. K4RNL's power supply.

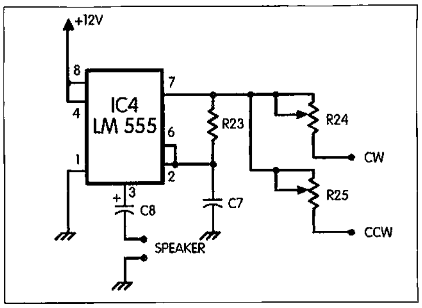

Fig. 3. K4RNL's audio oscillator.

Fig. 2 shows K4RNL's power supply; **Fig. 3** shows the audio oscillator. There are four important potentiometers in the aimer circuit: R1, R7, R8 and R9; and two in the audio circuit: R24 and R25.

R1 is the potentiometer used to control the rotation of the rotor, while R7 and R8 are used to adjust the rotor stop points when the rotor reaches the end of rotation. They are adjusted to turn off the aimer circuit when full clockwise or counterclockwise points have been reached.

R9 is used to adjust the delay time of the brake circuit. This adjustment allows for instant to several seconds of delay before the brake is applied. This an important feature; it allows the beam to coast to a stop before the brake is applied. A beam antenna, even a small one, can develop quite a lot of torque when stopped suddenly.

R24 and R25 are used to adjust the tones of the alarm while the beam is turning in one direction or the other—one tone for one direction and another for the opposite direction. This is an adjunct for the vision-impaired operator but can be deleted if it's not needed or desired.

The oscillator is plenty loud and, as in my case, a small speaker can be mounted inside the enclosure. A convenient spot is on the power supply board adjacent to the speaker connections. The values I have chosen in the oscillator circuit developed pleasant tones for me.

Fig. 4 shows the automatic beam-aimer circuit board (at 100% of actual size), ready for use with photocopier transfer system. **Fig. 5** is the component side of that same board, showing parts placement. **Fig. 6** shows the power supply board, and **Fig. 7** shows the component side of the board and placement of the components.

Photo A shows one of the partially completed beam-aimers. LEDs at the left and right upper corners indicate which direction the rotor is turning. At the lower left corner there will be a power switch and in the lower right corner there will be an LED "Power On" lamp. **Photo B** shows the main aimer board and the separate power supply board. Unfortunately, the power supply board is not the one with the oscillator. **Photo C** shows how I "stacked" the two boards in order to minimize the overall dimensions of the final enclosure. The current PC board layout allows the power supply board to be stacked above the main board for better heat dissipation.

Construction suggestions

Assuming you have etched or purchased the circuit boards, check all traces to be sure there are no breaks

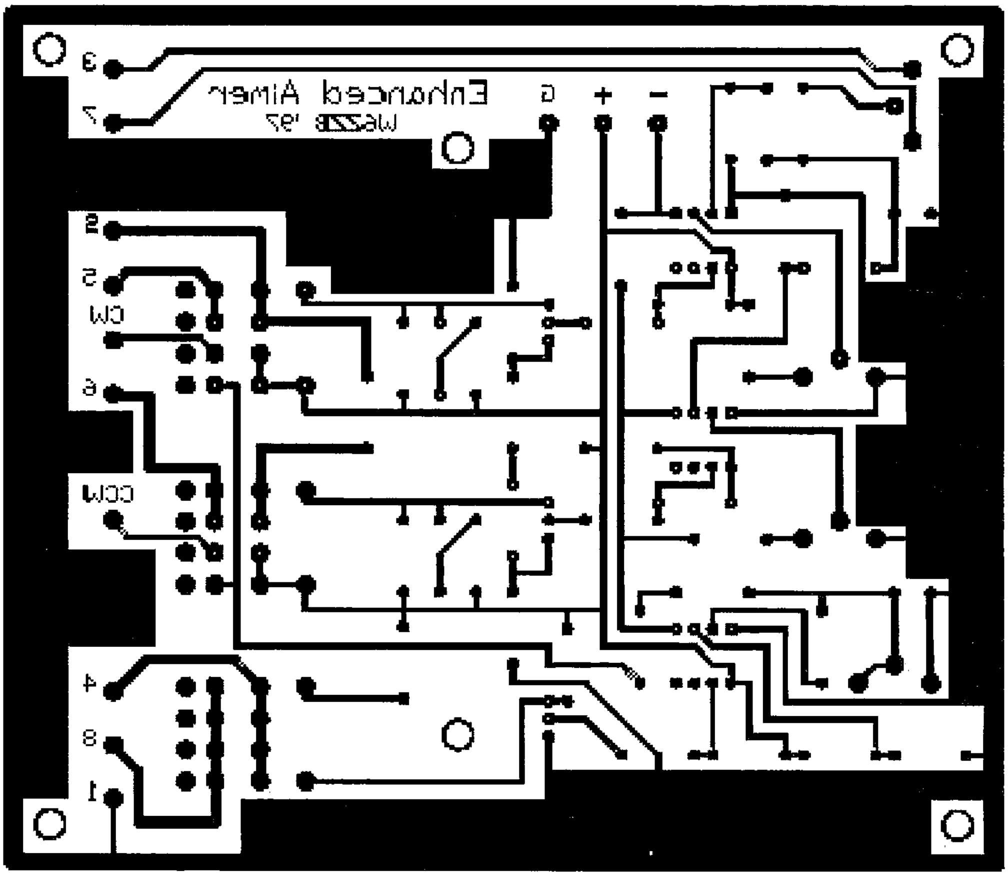

Fig. 4. Automatic beam-aimer circuit board, solder side (shown at 100% of actual size).

anywhere. Visual inspection may not be good enough so I suggest a continuity check using an ohmmeter. Assuming everything is OK, you may start installing the components.

I recommend completing the power supply board first and checking it carefully. Install a fuse holder and a fuse, the LED, the power switch and the AC cord. Plug the board into a source of AC and turn it on.

There should be ±12 volts DC between "G" and the positive terminal, and ±12 volts DC between "G" and the negative terminal. You can now check the oscillator by temporarily connecting a lead from the positive terminal first to the "CW" terminal, then to the "CCW" terminal, adjusting the potentiometers for a pleasing tone. Turn off the power supply and continue with the project.

In regard to the main board, I suggest strongly that IC sockets be used in all cases because if you happen to get a bad IC, it isn't easy to remove the IC without destroying the circuit board. I also suggest that these sockets, as well as the insulated jumpers, be installed first, then the rest of the components, with the relays installed last. Jumpers J1 through J9 are simply insulated wire jumpers. Check all the parts to be sure they are the right size and/or polarity.

When you have completed the installation of all the parts, connect the two boards together, with "G," "+" and "-" on the power supply board connected to similar points on the main board. Also connect "CW" and "CCW" from the power supply board to similar points on the main board.

Testing

You are now ready to do some checking. First, connect a 500 ohm potentiometer to terminals #3 and #7, with the arm of the pot connected to terminal #1. This will be your "rotor pot" for the following tests. Turn this pot fully clockwise. Also, connect a separate source of 12 to 15 volts DC, positive to terminal #3 and negative to #7.

Plug the aimer to a source of AC and turn it on. If the voltages are OK, proceed with the next test.

In the event the CCW LED is on, reverse leads 3 and 7 on the rotor pot, then adjust R7 to turn off that lamp.

Now turn R1 to about midpoint; the CCW LED should light up. Now turn the rotor pot slowly counterclockwise until the CCW LED goes out. Continue

turning the pot in the same direction and the clockwise LED should go on.

Turn both pots fully counterclockwise and adjust R8 so that the aimer circuit turns off; the CCW LED will go off. Now turn both pots fully clockwise and adjust R7 to turn the aimer circuit off and the CW LED will go off, too. Both of these adjustments will have to be repeated when you actually connect the aimer to your rotor control box.

A special note regarding the brake circuit: You must bring leads from terminals #4 and #8 to the inside of your control box and connect them to the "open" brake contacts of the direction control switch. In each of my cases I installed an eight-prong "Jones type" socket at the back of the control box, connecting all the numbered terminals to like-numbered terminals, except #4 and #8. This is the easiest method of putting it all together, believe me!

When you first rotate your new system, turn your beam to each extreme and again adjust R7 and R8 in order to turn off the aimer circuit. Also, adjust R9 for a few seconds of delay in order to allow the beam to coast to a stop.

Instead of a normal pot at R1, a 12-position switch might be installed with 2,000 ohm resistors between each contact. I tried this idea and was satisfied with the results. Now, instead of holding a switch while my beam turns I simply dial in the heading, and get back to operating!

Antenna Tuners

Do we really need them?

Robert W. Vreeland W6YBT
45 Maywood Drive
San Francisco CA 94127

Many hams use antenna tuners that are larger than their QRP rigs. Is this really necessary? While most transceivers are designed to withstand a three-to-one mismatch, this doesn't mean that they should be operated that way. I decided to find out what my MFJ-9020 would deliver to a purely resistive mismatch. It put out 3.3 watts into a 50 ohm load and 3.2 watts into 25 ohms. Not bad! The output dropped to 2.8 watts for 82 ohms, 2.6 watts for 100 ohms and a paltry 2.1 watts with a 135 ohm load. Apparently the MFJ-9020 prefers loads of 50 ohms or less.

Fortunately, most portable antennas will have an impedance in this range. According to Terman a half-wave horizontal dipole must be hung at a height of more than 1/7th of a wavelength in order to have an impedance greater than 50 ohms.[1] What a lucky break for 40 meter QRP fans! Can you hang a 40 meter dipole higher than 20 feet when you are out in the boonies with only trees for supports?

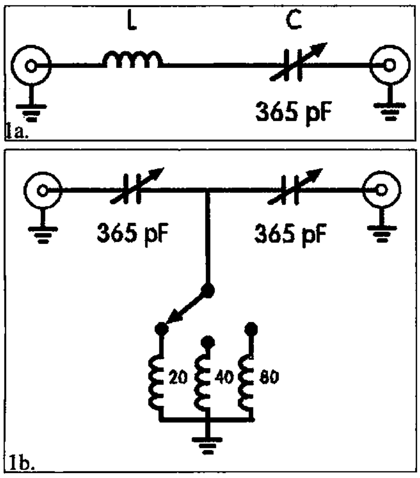

*Fig. 1. Miniature plastic dielectric variable capacitors can be used in extremely compact QRP antenna tuners. The circuit shown in **Fig. 1a** is useful for fine-tuning antennas that are close to resonance. For a wider range of matching use **Fig. 1b**.*

Circuits to try

So far we have only talked about purely resistive loads. What about that nasty thing called reactance? Most antennas have it and it really should be tuned out, which can be done by carefully adjusting the antenna length (usually not practical). An easier way is to insert either a capacitor or an inductor in series with the antenna to cancel its reactance. But how do you know whether you need a capacitor or an inductor? Usually you don't. The answer is to use the circuit shown in **Fig. 1a**. It is useful for fine-tuning antennas which are near resonance. At resonance, the inductive reactance is equal to the capacitive reactance and cancels it, leaving zero. At lower frequencies the circuit becomes a capacitor and at higher frequencies it is an inductor. This is a practical circuit. It can be made from a small plastic dielectric broadcast tuning capacitor (Calectro A1-233) and a toroidal coil. It is great for canceling the reactance of antennas with a radiation resistance near 50 ohms, such as a quarter-wave or a half-wave dipole. The circuit is not, however, an impedance transformer.

If we add just one more miniature 365 pF variable, we can build an impedance-transforming T network (**Fig. 1b**). It will give you a perfect match. This network is the smaller unit shown

at the top of **Photo A.** I used pin jacks instead of UHF connectors for the input and output. When used with my MFJ-9020 it matched 25, 50 or 100 ohms without any measurable loss. However, when I tried it with 18 watts and a 50 ohm load, I lost a watt. Better stick with QRP or the plastic dielectric in the capacitors might melt!

With my 27 watt MOSFET rig I use the circuit shown in **Fig. 2.**[2] The capacitors were borrowed from an MFJ tuner. Band changing is done with a jumper on a double banana plug. It grounds either the 20 or the 40 meter coil. On 80, the 40 and 80 meter coils are connected in series. To complete the unit, I added a VSWR meter using the directional coupler from a burned-out meter. The complete tuner measures only 5-7/8" by 3-1/8" by 3", and weighs just 1.25 pounds.

You may wonder why I chose toroidal coils rather than the higher Q air core ones commonly found in antenna tuners. Well, my home-brew tuner and the MFJ-900 both put out 26 watts into a 50 ohm load. However, for a 25 ohm or a 100 ohm load, the home-brew tuner was the winner by a watt or two. The toroidal cores are available from Amidon.

Oh, one other thing. How come manufacturers persist in packaging their standing-wave meters in massive plastic cases or even heavier steel ones? You can easily build your own and it will weigh less than half a pound. Two examples are shown at the bottom of **Photo A**. On the left is a toroidal transformer bridge (*ARRL Antenna Book*).

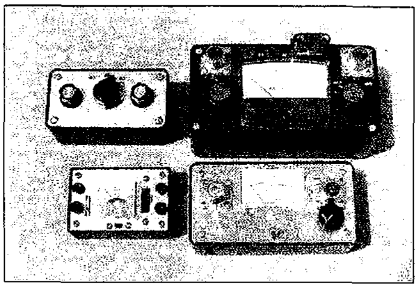

***Photo A.** Very compact antenna tuners can be built using toroidal coils and miniature capacitors. The larger unit is used with my 27 watt MOSFET amplifier. At the bottom are two types of standing-wave meters.*

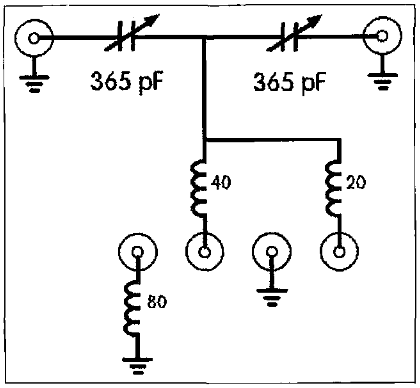

***Fig. 2.** This medium power antenna tuner utilizes air dielectric capacitors. A shorted double banana plug is inserted into jacks connecting coils for the desired band.*

This type of VSWR meter can be very compact. They are, however, a bit tricky to build and adjust. Most commercial tuners use a three-wire shielded transmission line as a directional coupler. Some use three silver-plated rods suspended in a metal trough. Others use three parallel traces on a circuit board. I built the one shown in **Fig. 3** and **Photos A** and **B** using a 6-1/2" length of RG-58 A/U. First I removed the outer plastic jacket. I then opened up the braid a little bit. Next I threaded two lengths of #22 tinned bus wire into Teflon™ spaghetti. I then threaded the insulated wires inside the braid, trying to keep them on opposite sides of the center conductor. The circuit is shown in **Fig. 3.** Be careful to keep the leads to the 1N67A diodes and the 150 ohm

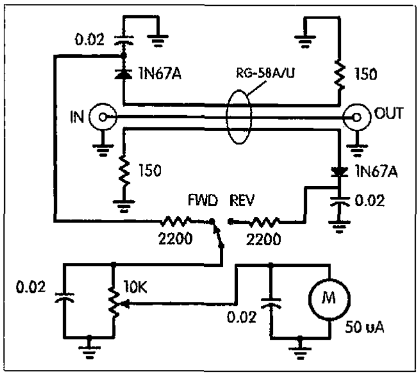

***Fig. 3.** A simple standing-wave meter using an RG-58 A/U directional coupler. The 2200 ohm resistors are RF filters. They also help protect the meter against burnout at maximum sensitivity.*

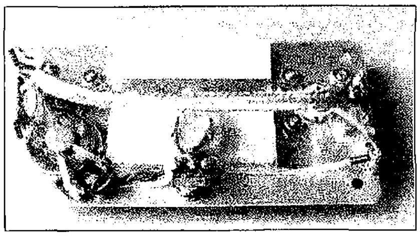

***Photo B.** A modified length of RG-58 A/U makes an ideal directional coupler. If carefully constructed with short leads, no adjustment will be required for a perfect balance.*

resistors very short, as shown in **Photo B**. If you can't find 1N67A diodes, use 1N34A. The RG-58 A/U braid should, of course, be grounded at both ends. I borrowed the calibrated meter from a discarded Radio Shack™ standing-wave meter. If carefully constructed, the result should be a perfectly balanced VSWR meter. It should need no adjustment.

While not absolutely essential, an antenna tuner can be a useful addition to any portable station, especially when less than ideal antennas must be used. This does not mean, however, that the tuner must be a gigantic box. Careful construction can result in a handy compact tuner, and a lightweight standing-wave meter.

The Topbander

A cheap and easy antenna tuner for 160 meters.

Kenneth Lowrey W8ND
7716 Oceola Lane
West Chester OH 45069

With the current sunspot cycle seriously affecting operations on the high frequencies, the 160 meter band presents some attractive wintertime operating alternatives. It is not plagued with QRM from foreign broadcast stations like 40 meters. The "top band" is not crowded like 75 meters and the operators are more friendly and more accommodating than some of the groups on 75 meters. Some have called 160 the "gentleman's band."

For many years I was under the impression that successful operation on 160 meters required long lengths of wire at high altitudes and miles of radials. However, not many of us can erect a dipole antenna that is 260 feet long—not many of us own the large area of land required for an extensive radial system. The good news is that we can still get in on the fun and action on 160 because none of this special stuff is essential on 160 meters! Granted, if you want to work DX regularly on the top band you would be advised to erect large antenna systems with as much height as possible. You will want to experiment with special receiving antennas, and be sure to include the best radial and ground system possible. However, routine operations such as rag-chewing and meeting your friends on 160 can be very rewarding without going to extremes on the antenna and radial systems. In fact, you can have loads of fun on 160 with just a small amount of effort.

The secret of my successful 160 operation, and the object of this article, is a home-brew antenna tuner which I call "The Topbander." I have worked stations over thousands of miles away with excellent results while running only 100 watts of power into a 75 meter dipole. I even made a contact with a QRPer who was running only 10 watts on SSB! QRP on 160? Yes, fun activities on 160 await you. All you need is a length of wire (it does not have to be a dipole) and The Topbander. The Topbander described in this article can be assembled in just a few hours. An added benefit is that this project is very kind to the wallet!

Construction

This antenna tuner is different from any other that I have seen because it uses no variable capacitors. The capacitors are fixed, and the inductance is variable. There are several reasons for not using variable capacitors. Variable capacitors for frequencies like 160 meters are large, difficult to find, and usually expensive. Large variable capacitors at these frequencies mean a lot of big plates, which require a lot of chassis space and take up a sizable part of the operating area as well. In addition, if you wish to operate with high power, even wider plate spacing is required to eliminate arcing during transmissions; this compounds the size problem. Furthermore, a large

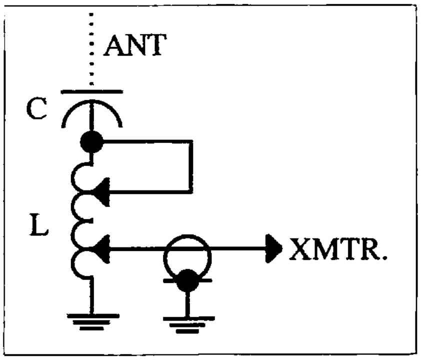

Fig. 1. The schematic diagram of the tuner is a simple series circuit.

antenna tuner looks out of place in today's high-tech, small-size-equipment operating environments. By using inexpensive fixed value capacitors you can eliminate the high cost of variables and build a tuner which is capable of high power operation but is still small in size. My finished tuner is mounted on a piece of wood and measures only 6" wide x 5" deep x 8" tall!

Fig. 1 shows the schematic for the tuner. Talk about simplicity! The components are a home-brew coil and a capacitor bank consisting of a series-parallel network. Start construction of the tuner by winding the coil.

My coil consisted of 40 turns of insulated wire. I used #14 solid copper wire, which is normally used for house wiring. The wire is close-wound, using the insulation as a spacer between turns. Yes, we have been told that power could be lost to the insulation due to coil heating, but this is more theoretical than actual; my coil shows no signs of running warm even after 30 seconds of keydown at 800 watts.

This tuner is designed for a 75 meter dipole with a feedline shorter than 65 feet in length. I have been operating on 160 for some time now with nothing more than a 75 meter inverted vee which is about 45 feet high at the center. In fact, one end is only 12 feet off the ground and the other is only about 18 feet high. The vee is a balanced antenna, fed with 450 ohm ladderline and works all bands from 80 to 10 meters. However, for 160, I short the ends of the ladderline together in the shack and feed the antenna as a longwire. If you have a coax-fed antenna, you can connect the center conductor and shield together and feed it as a longwire. If you use other than a 75 meter dipole, or your feedline is longer than 65 feet, you may need to tap your coil at different turns. In fact, you may have to change the tuner from a series arrangement (**Fig. 1**) to a parallel arrangement (**Fig. 4**) to get a low SWR. In either arrangement, the tuner is still very simple.

My experience has shown that the tap settings may change as the weather changes. Now, do not run to tell your friends that you can predict the weather from reading coil taps! The reason that the coil settings change with the weather is that the 75 meter dipole antenna is electrically short at this frequency. With

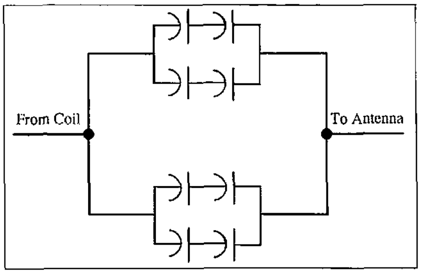

***Fig. 2.** The capacitor bank is a series-parallel network of 470 pF capacitors; total capacitance equals 940 pF.*

electrically short antennas, the higher the ground resistance, the more power is lost. Resistance in soil varies considerably due to changes in soil moisture and temperatures. As a result, variations in the soil conductivity around your ground system affect the number of coil turns needed for a resonant circuit at your location, and the placement of coil taps. So, even slight changes in ground resistance will affect the tuning circuit, such as after a rain or snowfall; the tap positions will also have to be changed as the soil dries during prolonged periods of drought. After a short period of operating under different weather conditions, you will discover where your coil taps should be placed to obtain the lowest SWR. The SWR does not have to be 1:1 to obtain power output. An SWR of 1.2 or even 1.5 may result in full output on 160.

Making the coils

To construct your coil, first cut an 8"-long piece of 2" schedule 40 PVC plastic pipe (note that 2" plastic pipe is the inside diameter; your coil form will be about 2-3/8" outside diameter). Then drill a small diameter hole about 1/2" from each end. Insert a small screw into each hole and slip on an eye-type connector before tightening the connection with a nut. Solder a length of # 14 solid copper wire into one of the eye hooks. Next, wind the wire on the coil form, and solder the other end of the coil to the hook on to the other end of the coil form. The coil should be tight against the coil form, but it may not be as tight as a factory-made coil, and a little "play" is acceptable. I found strips of duct tape to be useful in holding the coil in place during the winding and soldering process.

Several taps will probably be required on your coil. I had to start my taps at five turns from the ground end, and at three turns from the output end. Cutting coil taps in the wire insulation is easy; the secret is to take your time and try not to cut or nick the wire. I used a hobby-type knife to remove the wire insulation for the taps. Make certain that your blade is sharp, and make your cuts *very carefully.* Most hobby knives are very sharp, and you can cut yourself easily. Remember that this is amateur radio, and safety is our first concern.

Place the coil in a vise in a horizontal position, taking care not to crimp or damage the wire. Choose a coil tap point and make a vertical cut along one side of the wire, again trying not to cut or nick the wire. I made my tap cuts about 3/4" in length. At the top and bottom of your vertical cut make horizontal cuts across the insulation to expose the bare copper wire. It is advisable to "stagger" the taps so as not to interfere with adjacent tap points. I used small alligator clips to test the SWR, and when I found the tap positions which gave me the lowest SWR, I connected permanent coil taps. To do this, I used pliers to curl the end of a ring or eye connector, placed it around the bare wire, then crimped and soldered the connector to the wire. Be careful not to solder to the adjacent coil turns. Once the placement for the permanent taps were determined, you can make a new coil by unrolling the old one and using it as a pattern to determine the tap locations on the new wire. This is easily done if you place one end of both

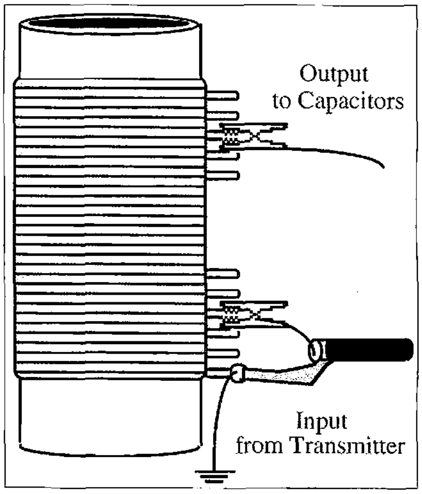

***Fig. 3.** Wiring the tuner is easy. Simply connect one alligator clip from the transmitter to the coil, and another clip from the coil to the capacitor bank.*

wires in a vice. You may decide, as I did, to use your prototype coil as your permanent one. This is OK too, if you did not nick the wire when removing the insulation. Remember that ground resistance changes with soil temperature and moisture content; make a number of QSOs over several weeks with your Topbander under different weather conditions so that you will know how many permanent taps you will need and where these taps should be placed on your coil.

You may choose to purchase coil stock instead of winding your own coil. A good choice would be an 8"-long coil with a 2-1/2" diameter, and six turns per inch.

The capacitor network

Next, build the capacitor network. Note that the capacitors are in a series-parallel network (**Fig. 2**). If you wish, you may substitute other capacitor values in your series-parallel network. If your capacitor values are different, then the number of coil turns required for resonance will also change. The formula for calculating series and parallel capacitance is found in all of the amateur handbooks and in most electronics textbooks. However, if you use the same schematic as **Fig. 2**, and all of your capacitors are of the same value, the total capacitance of your network will be *twice* the value of *one* capacitor in your bank. I used 470 pF capacitors and the total value in my bank of capacitors is 940 pF. Also, you do not need low tolerance capacitors; 20% tolerance is fine. If you have precision-value capacitors in your junk box go ahead and use them if you like, but they are not required for the success of the project.

You will need high-voltage fixed-value capacitors for this tuner. I used 3 kV capacitors in my circuit. My capacitor bank will take 800 watts of power at keydown for over 30 seconds without heating. Mica transmitting capacitors are probably the best choice for this application, but I used disc capacitors because that is what I had in my junk box. I used NPO disc ceramics to keep heat from affecting capacitance values, but NPOs are not required.

If you do not have any high-voltage capacitors in your junk box, there are several sources for them. You could cannibalize an older tube-type television

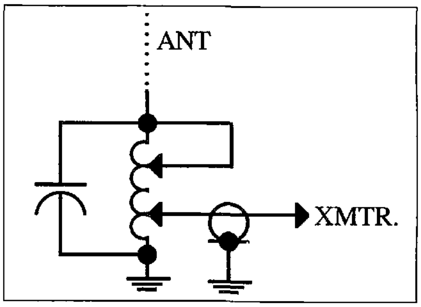

Fig. 4. An alternative diagram for antenna systems with feedlines longer than 65 feet.

chassis. Another source would be the flea market vendors at hamfests. If these efforts are not successful, ask around on the 2 meter repeaters or at your club meetings; sometimes other hams have transmitting-type capacitors in their junk box just waiting to be used. A fourth alternative would be to purchase the required capacitors from a retail vendor; they are usually not expensive. Some surplus dealers sell high-voltage transmitting capacitors. (Radio Shack™ stores generally do not stock high-voltage capacitors.). If all else fails, send me an SASE and I will help you locate the necessary parts.

I built my capacitor bank on a small piece of perforated board which measured about 2-1/2" square. In order to save space, I mounted both the perforated board holding the capacitor bank and the coil vertically on a piece of wood.

The wiring

The wiring of the tuner is very simple. Simply run a short piece of coax from the transceiver to the tuner and connect the center conductor to an alligator clip for the input coil tap (**Fig. 1**). Attach the coax shield and your earth ground to the low end of the coil. Then use another alligator clip for the other tap and connect it to the capacitor bank (**Fig. 3**).

Connect the output from the capacitor bank to the antenna, and feed it as a longwire. If you have a feedline longer than 65 feet, connect the capacitor bank *across* the coil (**Fig. 4**). Adjust the taps for the lowest SWR and you are in business with The Topbander!

If you want to do some very enjoyable hamming with low QRM during the wintertime, without huge antennas and without huge outlays of cash, then 160 and The Topbander are for you.

Build the Turbo Digi-Sniffer

A quick, cheap and easy digital field-strength meter.

Dave Pelaez AH2AR/5
7309 Centenary Dr.
Rowlett TX 75088

Whether you are involved in foxhunting, testing actual antenna performance or "sniffing out" leaky transmission lines, a sensitive field-strength meter (FSM) is an excellent addition to the ham shack.

The heart of this digital FSM utilizes an already-assembled liquid crystal digital display that has become available through numerous sources/distributors. I initially found one of these displays at the Dallas hamfest. Originally, the reason for buying the display was to use it in another application as a digital frequency readout for an amateur television downconverter. However, once I examined the display, I immediately recognized its potential use as a digital FSM. I returned to the hamfest the following day to get the name of the distributor, and much to my disappointment, couldn't find the guy who had been selling them—he must have packed up early.

Several months later I was in the Dayton, Ohio, area, and rediscovered another source for these displays: Midwest Surplus Electronics. I checked with the store owner and he verified that he had a reliable source for these displays, and Midwest Surplus also had all of the parts called for in this "Turbo Digi-Sniffer" article. (See the toll-free number and address at the end of the Parts List.)

The display

Described as a 3-1/2-digit LCD panel meter, the display is manufactured in Korea. The model number is listed as "PM-128." The panel meter comes already assembled and uses a dual-slope integration analog-to-digital converter circuit. It has a sample rate of three readings every second. The maximum voltage that can be measured with this display is 500 volts; this can be done by simply changing the value of two resistors. The display can be set up to read at the microvolt level so it can become the main building block for a digital field-strength meter.

Construction: digital panel meter modifications

The panel meter circuit board's silkscreened pads show a pair of pads marked "RA" and "RB" (see **Photo B**). The 1 megohm potentiometer that will

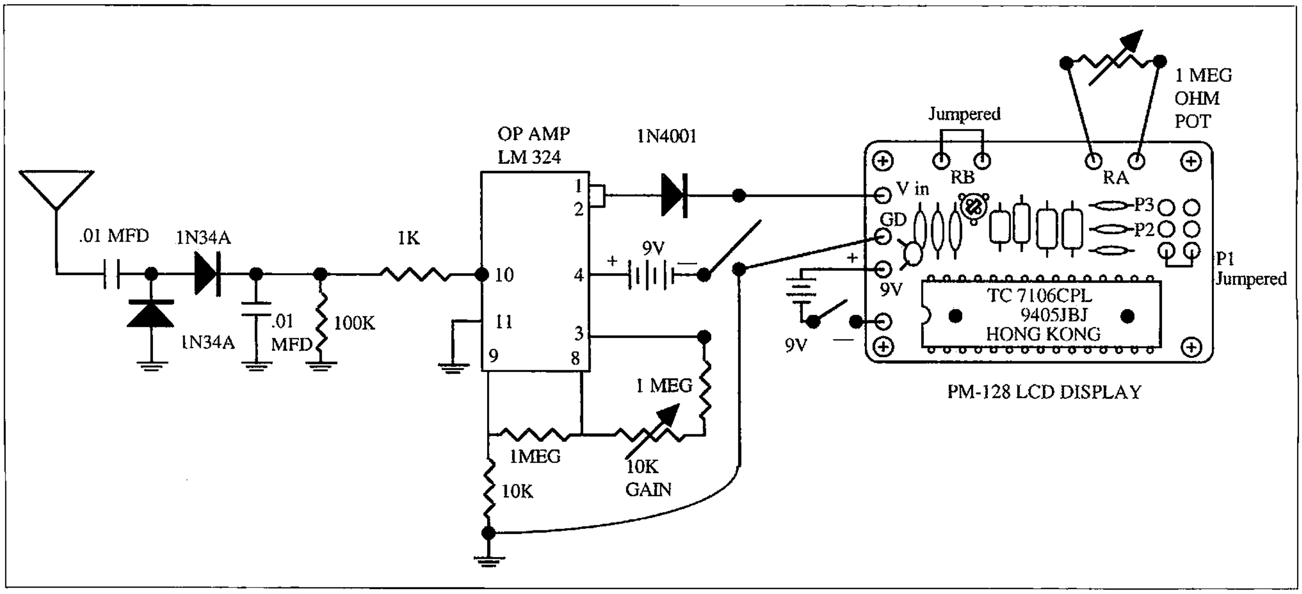

*Fig. 1. Schematic for the Turbo Digi-Sniffer. When using this circuit with the LCD display, the display and this circuit **must** have separate 9 volt power sources.*

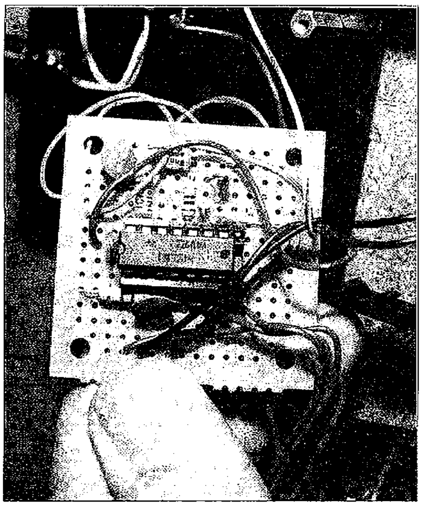

Photo A. The op-amp voltage multiplier circuit used in the Turbo Digi-Sniffer. Point-to-point soldering using perf board was the selected method of construction. Lead length is not critical.

be accessible from the front of the Turbo Digi-Sniffer should be connected to the junctions at RA. The potentiometer will now allow you to change the displayed voltage sensitivity. The junction pads at RB should remain jumpered together. The two P1 junctions also need to be jumpered together. The P1 modification sets the decimal point on the display as (.000).

Construction: the rectifier/voltage multiplier circuit

The rectifier/voltage multiplier circuit portion of this project has appeared in many electronic "recipe books." Aside from containing a passive rectifier circuit, it also contains an operational amplifier (LM 324) which is employed as a voltage multiplier. When coupled with a digital voltage display sensitive to microvolts, the display will be able to essentially detect voltage in the picovolt (billionth of a volt) range. This particular project will require two 9 volt batteries. As the op amp section is an active circuit design, it will require a 9 volt power source. The LCD display will also require an additional and separate 9 volt battery. Both of these batteries are connected through the DPDT switch. The LCD panel display pulls less than a milliamp of current, and because of this low current drain on the battery the display battery will last a year or more with normal use.

I elected to mount the rectifier/voltage multiplier circuit on some perfboard and point-to-point soldered this circuitry, populating the board by surrounding the 14-pin IC socket with the listed components. The actual circuit layout is noncritical, and the mount-and-solder method of placing the circuit components on the perfboard does not have to follow any particular order as long as it follows the schematic layout. Since I had a number of different types of antennas configured with a BNC, I chose to use one of the junque box chassis-mount BNC connectors I had. A UHF-style connector or even an RCA-style chassis mount connector would work fine as a way to connect an antenna to the Turbo Digi-Sniffer.

Once the rectifier/voltage multiplier circuit is complete, connect it to the digital display board. As a matter of interest, you can keep the cost of the project down by using junque box parts. Any germanium diodes will work (some may work better than others). The value of the RF choke and the capacitor also are not critical within the rectifier circuit. The aluminum chassis pictured was purchased at Midwest Surplus for $1.95. The Turbo Digi-Sniffer acted a little erratically when originally built into a plastic enclosure, possibly due to capacitive coupling with the hand and the tendency for RF to take other paths past the diode and choke. An aluminum chassis will rectify this situation. The most difficult part of this project was "hogging out" the window on the aluminum chassis for the digital display. The most time spent on this project was in preparing the chassis. It took less than an hour to solder the components and leads in place!

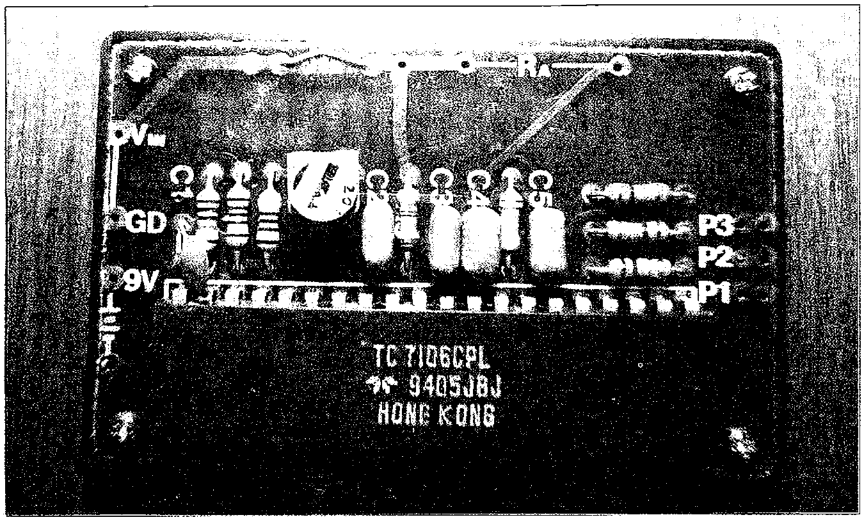

Photo B. Back of the LCD display, showing the silk-screened layout pads for the described hookup.

The smoke test

For initial alignment, the panel meter has to be on and you will need access to the 10k trimmer and the 10 megohm chassis-mounted potentiometer. You may need to go back and forth between the trimmer pot and the chassis-mounted pot to get the initial alignment in the ballpark. Try starting with a rubber-duck-sized antenna on the Turbo Digi-Sniffer and an RF source, such as a signal generator. Without a signal generator you could use an off-hook cordless phone or baby monitor. If the field is too strong for the counter to resolve or if the gain control on pins 8 and 3 of the LM 324 is too high, the display will go into an over-range condition, displaying the number 1, with no other digits. The chassis-mounted 1 megohm potentiometer controls the sensitivity of the LCD display, while the 10k trimmer controls the gain level of the voltage multiplier circuit. With the gain all the way up on the potentiometer, you will see that you will be able to adjust the 10k trimmer at the LM 324 to a level where there is a zero reading with no antenna connected to the Turbo Digi-Sniffer (with no nearby RF sources), but with an antenna connected the display will start detecting "far-off" RF sources. Be aware that these far-off sources may be a local AM or FM radio station, and the LM 324's gain control can attenuate these very weak signals. After proper adjustment, the display should read .000 with no RF field present. A nearby RF field will cause the display to show digits; the stronger the field, the higher the number displayed.

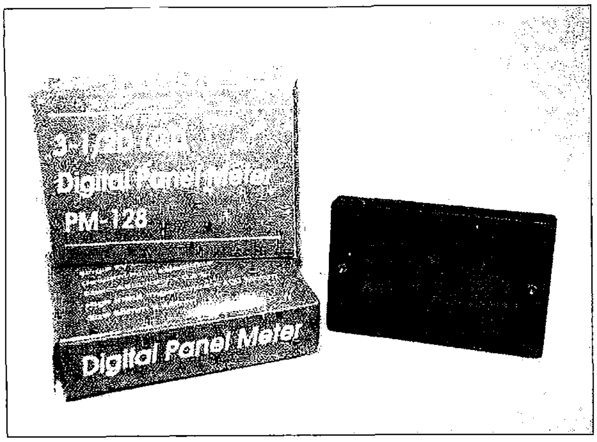

Photo C. Pre-built LCD with analog-to-digital converter.

Let's experiment

I've found that the Turbo Digi-Sniffer is sensitive throughout a wide range of frequencies. Also, keep in mind that different types of antennas on the Turbo Digi-Sniffer will also affect sensitivity at different frequencies. As this device is not calibrated, the emphasis should be placed on "relative" (in relative field-strength readings). Relative readings are extremely useful when checking out antennas or when out in the field sniffing for foxhunt transmitters. Do you want a really big scare? Try checking out your microwave oven using the Turbo Digi-Sniffer. Yes, Virginia, microwave ovens do leak!

When using the Digital FSM to detect RF fields, insure that the measurements are conducted at least two wavelengths from the transmitter antenna. Also remember to keep the Turbo Digi-Sniffer's antenna at the same orientation (polarization) as the transmitter antenna. Note that the metal chassis and the Turbo Digi-Sniffer antenna, if brought into an optimum plane, can become coupled with the transmitter antenna and become a part of the radiating system. Talk about some wild field-strength readings!

A perfect club project?

The cost of all the parts of this project can be kept at about $20 with careful shopping, and the Turbo Digi-Sniffer design is both simple and practical. What's stopping you, then, from organizing a club project one Saturday morning and putting together a barrelful of these useful test instruments for all the club members? 73

Parts List

Qty.	Part #	Description
1	29-01	LCD panel display
1		1 megohm potentiometer (chassis-mount)
1	4" x 2" x 2-3/4"	Aluminum chassis
1	RF-114	BNC female chassis mount
1	LM-324	Quad op amp
1	1N4001	Diode
2	1N34A (or equiv.)	Germanium diode
2	CD111	.01 µF disc cap
1		1k ohm 1/4 watt resistor
1		10k ohm 1/4 watt resistor
1		100k ohm 1/4 watt resistor
2		1 megohm 1/4 watt resistor
1	VR207	10k ohm single-turn trimmer pot
1	ICS2	14-pin IC socket
1	570-21	Mini chassis-mount DPDT toggle switch*
1	JALPC-1	Perf board (you cut to size)
2		9V battery connectors

Note: All parts can be ordered from Midwest Surplus Electronics, P.O. Box 607, 501 W. Main St., Fairborn OH 45324; (800) 523-3690.

* DPDT chassis-mounted switches are available at Midwest surplus, so they are used here in lieu of the DPST (double-pole single-throw) switch used to switch on and off the two 9 volt batteries. The double-throw portion of this switch is not used for this project.

Sumas Mountain High

Building a self-sufficient repeater tower on a British Columbia mountain.

Will Imanse VE7BID
211-33370 Nelson Ave.
Abbotsford BC
Canada V2S-2L8

In the center of the 80-mile-long Fraser Valley in British Columbia, Canada, sits 3,000-foot-high Sumas Mountain. This hill is situated perfectly to give a clear, unobstructed view that stretches (from west to east) from the east coast of Vancouver Island almost all the way to the town of Hope, and southward into the United States to well past the city of Bellingham, Washington.

Several years ago the hams of Abbotsford BC, at the base of the mountain, dreamed of putting a repeater on Sumas. Our dream has finally become a reality.

We chose a site on a ridge at 2,750 feet. The Fraser Valley Amateur Radio Emergency Services Society applied for a government lease and was approved. Next came the challenge: Building and running a repeater site with no available power in the foreseeable future and very limited vehicle access.

The designers decided to use solar power; later we added wind power. The British Columbia Telephone Company donated a 50-foot tower in return for a small donation to the Telephone Pioneers of America Society. A donation of cinder building blocks from the local Blackwood Building Supply and Home Hardware store helped, too. One of the local hams, an experienced bricklayer, was put in charge of constructing the building. Another ham with cement experience (and a truck for the job), took care of the cement work and getting the materials to the site. The tower work was done by a ham who worked in the tower construction field. Teamwork and cooperation from a number of other hams helped create a professional-looking site. A small solar-powered commercial site not too far from ours looked *amateur* by comparison!

***Photo A.** Storms are common up here, so the guys are heavy-duty.*

We erected the 50-foot tower next. We drilled down into the stony mountainside three feet in four places for the base and epoxied threaded steel rods into the rock. The tower was then put into position, with a 20-foot-diameter H fixture installed at the top for the antennas. The vertical pipes at the end of the H fixture were extended above and below for both upper antenna and lower inverted antenna mounting. This allowed for eight antennas to be mounted on the tower without having to mount them on the face of the tower itself. We also added an anti-climb shield and gate to keep unauthorized visitors off the tower.

The tower was supposed to be self-supporting, but with the amount of weight at the top we decided to add guys. As you can surmise from **Photo A**, the mountaintop winds can be fierce.

Next, we added a donated chain link fence, then a second tower—an 80-foot guyed tower, donated by the local Rogers Cablevision outlet. It was also installed with two H fixtures, providing room for six more antennas. With some more small donations to the Telephone Pioneers, we obtained some antennas and heliax waveguide.

The main VHF repeater is on 146.60 MHz and the UHF repeater is on 442.025 MHz. We also have a packet repeater, a full duplex UHF link for phone patches to Abbotsford, and a 1.2 GHz FM amateur television repeater with two remotely-controlled cameras, mounted on the two towers. These cameras can be tilted and panned by tone control. They allow us to check conditions and monitor any intrusions at the site. They also allow fantastic views up and down the valley. An outside speaker and microphone can be activated remotely to communicate with people at the site. A planned motion detector with announcement on the VHF repeater will also alert us to any intruders.

All the equipment runs from 16 solar panels at the site. Eight are located on the roof of the building; the other eight are on one tower. The panels on the tower can be for winter and summer sun angles.

We've tried a number of windmills, but so far four of them have self-destructed. The first, a 75 watt model, lasted a few months. The next three were 300 watt models. One lasted less than a day, and another less than a week—and that after the manufacturer assured us that they were almost indestructible. The current 300 watt model is still running—we're keeping our fingers crossed.

At the same time, we also put up a 55-foot self-supporting tower in the town of Hope, 50 miles to the east. A VHF repeater at 147.08 MHz was installed in a cabinet on the side of the tower. Now we're working to link the Abbotsford and Hope repeaters, and then expand farther east via links into British Columbia's interior.

We're proud to have built such an impressive repeater site. Our group has solicited all the donations to the cause, and in some cases donated our own equipment and funds. The cooperation among the group of amateurs that took on this project was first rate. There was seldom a problem securing volunteers for a work project. *This* is what amateur radio is all about. 73

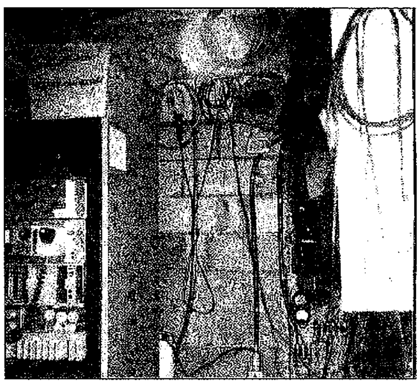

***Photo B.** Keeping some spare cables and other items on hand helps. The main and secondary 2m repeaters are visible on the left.*

third the cost. With the number of government employees now outnumbering our manufacturing force, it does tend to make everything we let the government buy for us cost at least three times normal. And that's on a good day.

If Congress would allow competition, we'd have private mail services providing two deliveries a day, with first class mail for 10¢, according to expert estimates. If you'd like to get really upset over our mail service, read *Monopoly Mail* by Douglas Adie, Transaction Publishers, Rutgers University, New Brunswick NJ 08903, ISBN 0-88738-747-0, 197p.

As long as you're content to work the first four hours of every day for the government and the rest of the day for yourself, the situation is just going to get worse. Yes, the government comes first. They get your money without your ever even seeing it.

What can you do about the mess? Well, I've already explained that. Let me boil it down for you. 1. Never re-elect anyone. Keep flushing the political toilet. And don't re-elect anyone ever again in the future. We don't need to worry about term limits if you'll flush the toilet every two years. 2. Let's get some hams into our state legislatures.

Justice

A letter from a reader mentioned that the medical industry scams are at least matched by our criminal justice system. I love the euphemism. Justice system, indeed. And how about our "correctional facilities"? That's about the last thing they do. Anyway, Leigh writes, "They don't care who's guilty, they just need convictions, and they need to keep the minorities stirred up just for job security. They will gladly send an innocent person to prison to further their careers. I'm told that Sandra Day O'Connor made it to the Supreme Court on cases where the evidence was manufactured by a crooked lab that used to operate in Phoenix. After their methods were discovered they closed shop and moved their business to Texas, but very few cases were retried as a result."

Surely Leigh must be exaggerating. No American would ever do anything like that, would they? For some reason that reminds me of when I was a TV producer-director and I got to know a New York City police detective who wanted to blow the whistle on what was going on. For instance, he told me about a cooperative dentist just down the street from the station house where they'd take prisoners. The dentist would drill the guy's teeth with no pain killer, right down into the nerve, one after the other, until he signed a confession. The dentist would then fill the teeth and nobody could prove anything. He said they always got confessions. The exposé program we were planning fell apart when my friend suddenly disappeared. He's never been heard of again.

I also remember my first court case in New York. I had a simple open and shut case, but my lawyer said I would have to give the judge $5,000 if I wanted to win. I didn't see how there was any way to lose so I didn't pay. I lost.

Then there was the time I was a witness in a murder case where I had critically important testimony to give and was not allowed to give it. The murderer got off with a slap on the wrist. So much for swearing to tell the truth, the whole truth, and nothing but the truth. Not in *our* courts.

There sure are a lot of things we need to fix to make this the country it could and should be.

Though I've had millions stolen from me, with no punishment for the thieves, I'm still optimistic. Heck, I can always make more.

Have you had any interesting experiences with our "justice" system?

AIDS, HIV, and Other Baloney

Yes, I've been reading again, and it wasn't the new *ARRL Handbook* either. Unless you know someone with HIV or AIDS (or both), or are curious about all the fuss, you may not be interested enough to go out and buy the new Peter Duesberg book, *Inventing the AIDS Virus*. It's a $30 722-pager and it nails the medical establishment to the wall for the mess it's made of this whole business.

Since I've read in several places that there are thousands of AIDS patients who are HIV negative, and millions of HIV positive people with no sign of AIDS, Duesberg's claim that AIDS is a lifestyle disease, particularly involving the use of recreational drugs, makes sense. He further provides exhaustive proof that AZT, which is a chemotherapy used to treat AIDS, actually is responsible for causing AIDS. He also provides proof that AIDS is not in the slightest infectious.

AIDS is actually the result of a toxic buildup from drug use. Remember the drug culture of the '60s? Well, is it really all that surprising that people's bodies eventually reacted a few years later? And since drug use is particularly rampant in the homosexual culture, this explains why the syndrome hit this group so strongly. It's similar to cigarettes, where it takes a few years of poisoning one's body with nicotine and tars before emphysema, heart trouble, lung cancer, and other illnesses caused by defeating the body's immune system inevitably appear. These drugs lower the effectiveness of the immune system, allowing any opportunistic disease to win out.

Our bodies harbor billions of microbes. Indeed there are more microbes than cells in our bodies, so our immune system is in a constant war with invaders. Anything that tends to lower the immune system can allow the bad guys to win. Our immune system suffers when we are stressed, when our bodies don't get the required nutrients, if we shortchange it on water or oxygen, or load in toxins.

Add a Microphone Preamplifier to Your 10 Meter Rig

Low-cost speech processing can increase your power.

Phil Salas AD5X
1517 Creekside Drive
Richardson TX 75081

Over the past few months I've been playing around on 10 meters. Ten meters *does* open up even in these days of low sunspot activity, and due to the large number of Novice and Tech-Plus hams, there is enough activity on 10 meters that it's pretty easy to know when band openings do occur. Also, there are some tremendous bargains available in 10 meter rigs. The Uniden, Ranger, Lincoln, Emperor, and Radio Shack 10 meter rigs are showing up at very good prices (I guess the folks who bought them during the sunspot maximum are dumping them because they think 10 meters is dead most of the time).

I currently own both a Uniden HR-2600 and a Radio Shack HTX-100. (I know, I know—why do I need both a Uniden 2600 and a Radio Shack HTX-100? Well, we have two *cars!* See how easy it is to justify multiple rigs?) Anyway, when running some tests on these radios, I saw a very distinct average output power variation between these rigs. On my analog power meter (Diamond SX-1000), average talking power is around 5-6 watts on the Radio Shack HTX-100 and only about 1-2 watts on the Uniden HR-2600. Looking at the S-meter on my test receiver (my Icom IC-706), I saw a 2(!) S-unit peak difference in favor of the Radio Shack radio. With both the Radio Shack and Uniden radios, I could whistle-up the power to the advertised 25 watts output; however, the Radio Shack rig did a much better job of keeping the "talking power" up. Hmmm. So what could I do to my Uniden to make it better?

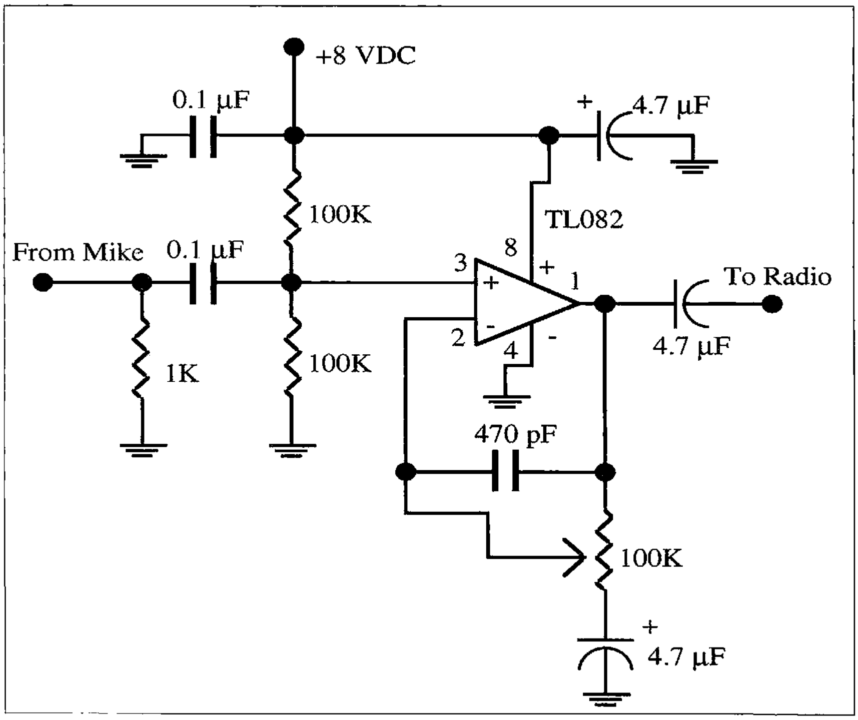

Fig. 1. Dynamic microphone preamp.

"Up" your talk power

After examining the Uniden 2600 schematic (with a magnifying glass—it is small!), I determined that there is no obvious microphone gain adjustment in the radio, so I decided to build in a microphone preamp that would give me equivalent "talk power" to the Radio Shack rig. My final circuit is shown in **Fig. 1**.

I selected the RC values to give around a 300 Hz high pass, and a 3,000 Hz low-pass cutoff. I traced the Uniden microphone connections to the main board (red and black wires), cut the red (hot) wire and inserted the circuit shown. For powering, I probed around on the PC board until I found a source of 8 VDC (regulated) and ground and tapped into these points.

Then, while talking into the microphone, I adjusted the potentiometer for the same 5-6 watts average power as seen on the Radio Shack rig. I also listened to my voice on my IC-706 and verified that there was no distortion. My final tests occurred on the air. Comments from stations I worked included "excellent audio" and "good crisp modulation." I highly recommend the addition of this preamplifier circuit to your Uniden radio.

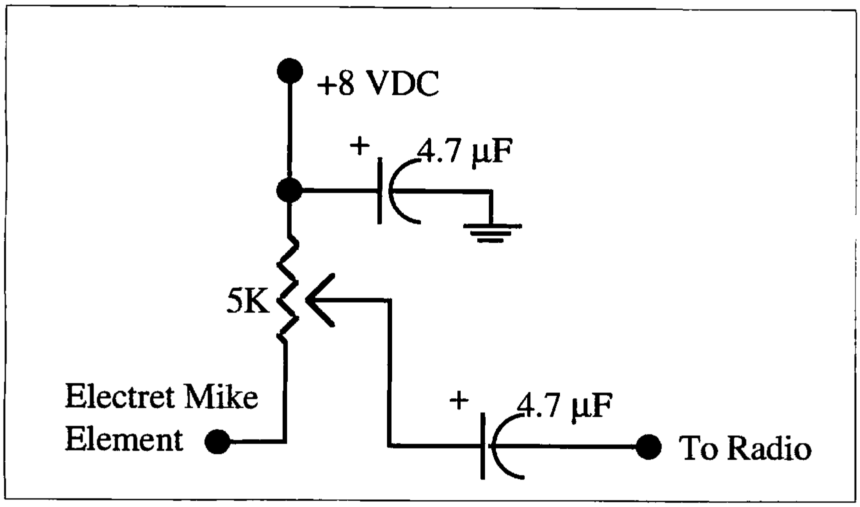

Fig. 2. Electret mike element powering.

Change the mike element

A friend of mine, Bob N5UPF, owns a Uniden 2510. This radio had a dead microphone. Since the Uniden 2510 and 2600 share the same microphone, I borrowed Bob's radio to check the "average" power and found it to be similar to that of my unmodified HR-2600. I also verified that Bob's microphone element was dead. Finding a replacement dynamic microphone element for this microphone is difficult, and dynamic elements are relatively expensive. Since Bob's 2510 could benefit from increased microphone gain, I decided to substitute a Radio Shack electret microphone element for the dynamic element. These electret elements are very small, inexpensive, easily obtainable, and they have gain.

Unfortunately, these mike elements also require powering—but this turned out to be a pretty easy fix. First, I stuffed the new tiny electret element into Bob's microphone case, added a drop of epoxy to hold it in place, and then packed a piece of foam rubber behind it to fill the large cavity left by the dynamic element. Next, I traced the microphone wires into the radio. The hot wire turned out to be a yellow wire in a large, connectorized bundle of wires. I cut this yellow wire and inserted the circuit shown in **Fig. 2**. Again, I probed around on the PC board to find a source of regulated 8 VDC and ground. Anyway, when everything was finished, I ran my "average" power tests while adjusting the potentiometer so that Bob's 2510 put out the 5-6 watts of the HTX-100 and my preamplified HR-2600.

Since I completed the above projects, my HTX-100 microphone failed. What *is* it about these dynamic elements? Anyway, I built the same electret element and powering circuit as shown in **Fig. 2** into my HTX-100. In the HTX-100, the front panel circuit board uses solder bridges to attach to the main circuit board. I probed around on the solder bridges until I identified the microphone "hot" wire, removed the solder bridge, and substituted the **Fig. 2** circuit across the gap. An adjacent solder trace had the 8 VDC I needed for powering the mike element. Again, I adjusted the potentiometer for the 5-6 watts average power output on my analog power meter.

Some radios can probably benefit from increased mike gain—I know the Uniden radios do. It is pretty easy to build a microphone preamp or replace a dynamic mike element with an electret mike element. Since the Uniden radios use ALC to limit the maximum transmit power, we are effectively getting some audio speech processing due to the combination of additional microphone gain and ALC limiting. Finally, both of these circuits are physically small and easily fit inside most any radio. Now if 10 meters would just open up a little more often!

Hamtronics RWX Storm Watch Weather Broadcast Receiver

Hams need to know about storm emergencies.

Dean Lewis WA3WGV
1193 Azalea Lane
Palatine IL 60074

The NOAA Weather Radio (NWR) broadcast system transmits on seven discrete 25 kHz-spaced frequencies between 162.400 and 162.550 MHz from over 425 stations covering all 50 states, adjacent coastal waters, Puerto Rico, the U.S. Virgin Islands, and U.S. Pacific Territories. The system currently covers 70 to 80 percent of the U.S. population; the current expansion program will increase coverage to 95 percent. NWR has been designated as the sole government-operated radio system to provide direct warnings for both natural disasters and nuclear attack, with plans to include warnings for all hazardous conditions that pose a threat to life and safety, both at a local and national level.

The Hamtronics model RWX is a highly sensitive and selective, professional quality seven-channel crystal-controlled double-conversion FM superhet receiver for the 24-hour NWR broadcasts from the National Weather Service (NWS). You can listen to the current weather report and forecast at any time; or, when set to "Storm Watch," the receiver will remain silent until it receives an alert tone from the transmitting station, opening the squelch so the user can hear the emergency information that follows. Crystals for all seven NWR channels are supplied.

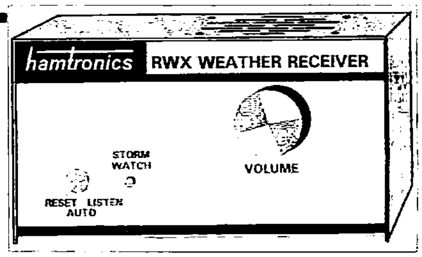
The receiver provides room-filling volume at less than a quarter turn of the front-panel control, so there's plenty of reserve for noisy locations, mobile use, or to hear alarm-activated announcements in another room. Circuit board terminals are provided for an external speaker. Sensitivity and selectivity are excellent. For all the audio volume and features, the assembled unit is a convenient size. The alarm output can be used, through a relay, to drive secondary alarms for those with special needs: a loud bell, flashing light, bed-shaker, etc. In its full kit or assembled form, the receiver comes with a high quality plug-in-the-wall power supply. For temporary portable use it can be powered by any source from a car cigarette lighter to 12 volts worth of AA cells, or a 9 volt battery. Watch battery polarity carefully.

> ***"The Hamtronics model RWX is a 'must have' for hams or for anyone else involved in or affected by emergency operations due to weather."***

The RWX is available in kit form, with or without the cabinet/speaker/AC power supply, or fully assembled, tested, and installed in the enclosure. Appropriate assembly and/or operations manuals are supplied with the radio in either case.

Circuit description and assembly

RF input at 162 MHz is amplified by a low-noise dual-gate FET. Double-tuned circuits provide rejection of images and out-of-band signals. The first mixer converts the 162 MHz input to the first IF frequency, 10.7 MHz, which goes through a ceramic filter on its way to an integrated circuit IF amplifier. The injection signal for the first mixer comes from a 16 MHz oscillator controlled by



the seven switched frequency systoles. The signal is tripled twice, with double-tuned circuits in each tripler.

The IF amplifier chip contains a crystal-controlled 10.245 MHz oscillator, the second mixer with an output at the second IF frequency (455 kHz), a narrowband ceramic filter, and a quadrature detector. The IC audio output is applied through the volume control to an IC audio amplifier chip, which supplies both the internal and external speaker terminals on the circuit board.

The IF amplifier chip also provides the tone alert squelch function, responding to the 1050 Hz NWS-transmitted alerting tone.

Like their RWWV receiver (see review in *73*, December 1995), the circuit board is FR-4, double-sided, with a continuous ground plane on the top surface; all holes are drilled and plated-through.

Follow the detailed assembly instructions carefully; the suggestions and clues are invaluable for getting good results. As in any VHF circuit, short leads are important. This is a quality circuit board; the parts all fit well, holes are properly positioned, and components solder in easily.

Following the assembly, an RF signal generator and a sensitive DC voltmeter are needed for alignment; full step-by-step instructions are included. Tables of test voltages are provided; if you can build and align the receiver, you can troubleshoot it if necessary. In case you

move or take the receiver to other locations, make a copy of the "Switch Position vs. Channel Frequency" list from the instruction manual and tape it inside the receiver.

Performance

A seven-position DIP (dual inline package) switch, or rather, set of switches, selects the crystal-controlled frequency. The switches are mounted on the circuit board, and are easy to operate with a small straight-blade screwdriver. With the frequency selected and the receiver closed up, only the necessary controls are available on the front and rear panels: volume control, Reset/Auto/Listen switch, a Storm Watch LED, and the BNC antenna connector.

Operation is straightforward. To listen to the current broadcast, set the front panel switch to "Listen." Pushing the switch all the way to the left and releasing it puts the receiver in "Auto" mode and turns on the Storm Watch LED. The radio will remain silent until it receives an NWS-broadcast alert tone. The tone opens the squelch and activates the audio at your pre-set volume.

The quality 12 VDC plug-in power "brick" supplied with the receiver provides hum-free reception.

The BNC antenna fitting is mounted on the rear panel; get a right-angle adapter for mounting an antenna right on the radio. From my location northwest of Chicago, a quarter-wave whip on the back of the receiver provides loud/clear reception of the NWR signal off the Sears Tower, 28 miles away (but then, so does a 3-inch length of wire!). The whole idea, of course, is reliable reception of your local NWR station, but I couldn't resist trying a little DXing. On a warm afternoon, with tropospheric propagation helping out, the following came in clear and strong with a 2 meter AEA "Hot Rod" antenna (telescoping end-fed half-wave), indoors: Rockford, IL (54 mi.); Milwaukee, WI (65 mi.); Grand Rapids, Michigan (140 mi.); Adams, Wisconsin (160 mi.). (Consider the additional value of the NWR stations as 2 meter propagation beacons!)

If you're located anywhere near an NWR transmitter, you should have no problem with a small indoor antenna. In more rural areas, try an outdoor ground plane, or even a vertical yagi. RadioShack™ carries a line of "scanner" antennas that should work well; amateur 2 meter antennas should work just fine.

I've owned weather receivers before. Some have been good for little more than modification to monitor local 2 meter repeaters, some have had serious intermod problems, and most have lacked sensitivity. This is my first that could be called a serious, professional-grade receiver, including the tone alert function; it provides a real measure of confidence that important emergency information will not be missed.

Call your local office of the National Weather Service for the local frequency (or just switch through the seven frequencies until you find it), and the day and time of their tone-alert test. Most seem to be on Wednesdays at noon (ours happens to be Tuesdays at 11:00 a.m.). While you're at it, ask for the current location/frequency list bulletin and other information on NOAA Weather Radio they have available. It's a good idea to monitor the tone alert test occasionally, to ensure proper activation of the Storm Watch function.

Conclusion

The Hamtronics model RWX is a "must have" for hams, CAP, Coast Guard Auxiliary, Police and Fire Departments, schools, hospitals, truck and taxi dispatchers, Scouts, outdoors enthusiasts, or anyone else involved in or affected by emergency operations due to weather. It's easy to use, well-built, sensitive, and dependable.

The RWX is available as a board-level kit for $79; board, cabinet, speaker, and power supply in kit form for $99; or fully assembled and tested with the cabinet, speaker, and power supply for $139.

For further information, a catalog, or to order the RWX, write to Hamtronics, Inc., 65 Moul Road, Hilton NY 14468-9535, or call them at 716/392-9430; FAX 716/392-9420.

The Telegraph

A little device that changed the world.

L. VanProoyen K8KWD
8330 Myers Lake NE
Rockford MI 49341

As we approach the millennium in this "information age," we have access to a variety of communication technologies. This is the story of how the forerunner of them all, the electric telegraph, came to be.

The Morse code

Di-di-dah-dah-di-dit—dots and dashes. When you hear the sound, you most likely think of Morse code—right? But did you know that Samuel Finley Breese Morse's original telegraph system was not based on sound at all?

Dating back to the mid 1830s, Morse's original "receiver" was a lot like a chart recorder. It marked patterns of the making and breaking of an electrical circuit at the sending station onto paper tape. The sending station "keyed" the circuit according to an early code devised by Morse, a forerunner of the familiar dot-and-dash code still in use today—and the traditional telegraph key (**Photo A**) hadn't been "invented" yet either.

Only much later, using a modified receiver, clever "operators" learned to recognize rhythm patterns in the receiver's "click-click" sound, and found that they could translate directly from sound to text. This receiver was subsequently refined into the familiar "sounder" similar to that shown in **Photo B**.

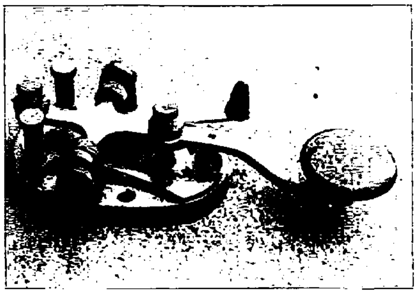


Photo A. The telegraph key.

Morse is perhaps best known for the code that bears his name, but his approach to developing an electric telegraph, pioneering the simplex circuit (one wire pair) and using a quasi-digital signaling code, was unique. It made building a telegraph system possible and led to the communications systems we use today.

Following early trials, Morse's telegraph rapidly spread throughout America in the 1850s. Morse code, as it evolved, went on to become a world standard that has lasted over 175 years. As wireless and radio came of age, the merchant marine also adopted the code as its international standard, pretty much assuring the US a position of technological leadership in the field of telecommunication.

"Now closing down continuous watch. Fair winds and following seas with 73s from all of us." With this transmission at 8 PM (0000 Hours GMT), July 31, 1993, the U. S. Coast Guard ended nearly 50 years of continuous watch on 500 kHz, the international maritime distress frequency. On March 31, 1995, the Coast Guard discontinued all other regularly scheduled use of Morse code. Today, there is virtually no formal use of the Morse code by the US Coast Guard or military. Newer technology—satellite communication, ship-to-shore teleprinters, and the like—is said to have made Morse code obsolete.

Technology changes but the need to communicate continues. Today, there are many technological choices, and high speed data systems have great impact on almost everyone's life. Computers, linked by digital data systems, virtually run the world.

Information is readily available. The data highway, Internet, packet webs, cellular phones, and cable are examples. Getting the message is not the problem it was in the '40s (1840s, or for that matter, 1940s). Perhaps knowing what to do with all the available information, differentiating quality from junk, is today's problem.

Standing on giants' shoulders

As with virtually all inventors, Morse didn't start in a vacuum! In the 1830s, many dreamed of building a telegraph, and some already had telegraph schemes on paper. By the time Morse started developing his ideas, a few others were well underway in perfecting theirs. Chief among these were Charles Wheatstone and Edward Davy, both from England, and both received British "telegraph" patents by 1837.

Wheatstone, now known largely for the Wheatstone Bridge, was an electrical experimenter in the 1830s. He gained early notoriety designing a method which rather accurately measured electrical propagation speed through wire in 1834. The system used a rotating mirror scheme similar to the classic Michelson velocity-of-light experiment.

Wheatstone went on to develop his telegraph over the following years. It initially used five circuits, each terminated with a galvanometer-like device (**Photo C**). Each such device had a pointer that could assume any of six positions according to the current level in its circuit, and with five circuits, Wheatstone could communicate 30 characters—albeit very slowly. Because of the five-line requirement and message coding/decoding difficulty, it was doomed to failure as a practical telegraph system. However, Wheatstone's galvanometer detector would later be modified to use a mirror as the indicator and find application in the first Atlantic telegraph, but that's another story.

Later, working together with William F. Cooke, another telegraph inventor of the time, Wheatstone refined the design to require only three circuits and indicators. This basic system would find early use in England and parts of Europe.

Edward Davy also received a British telegraph system patent in 1837 because of a couple unique features his system had. It was a multi-wire device like Wheatstone's and Cooke's, but Davy designed a repeater circuit which in itself would find later use by others in relaying signals over long distances.

In Germany, experimenters made an early discovery that would also be of use to later telegraph builders. They discovered that a single wire could be used in a (telegraph) circuit if the earth were used to complete the circuit pair (one leg grounded at each end of the link). This discovery was not generally known until after 1837, so Morse did not make use of it initially. Also, Morse's first major test link was begun using an underground line which would have been difficult to insulate, given the state of wire insulation quality at the time.

There was another development, in electrical technology which would prove beneficial to telegraph builders—the battery. Until its emergence, most electrical experimenters were limited to using a galvanic cell which produced about 1 volt. John William Daniell, an Englishman, discovered that cells could be connected in series to form a battery. The increased voltage available from such a battery would solve many problems caused by wire resistance and other circuit losses in telegraph lines. Keep in mind that while Georg Ohm had already formulated his "Ohm's Law," these principles were still a mystery to most electrical experimenters of the time.

America's Joseph Henry was another contributor to the telegraph's development by providing advice and theory on electromagnetics. Since most of the contending electric telegraph systems employed some sort of electromagnetic receiving device, the emergence of sensitive and efficient electromagnets solved a major problem impeding the development of long lines.

There were many more contributors whose ideas were "borrowed" and used in the development of the electrical telegraph.

Putting all the pieces together

Exactly how Morse acquired the various pieces of technology needed to produce a functional cross-country electric telegraph has long been debated. His early notes, for example, indicate he had a basic knowledge of electromagnetic devices. How he acquired this knowledge was the basis of a lawsuit brought

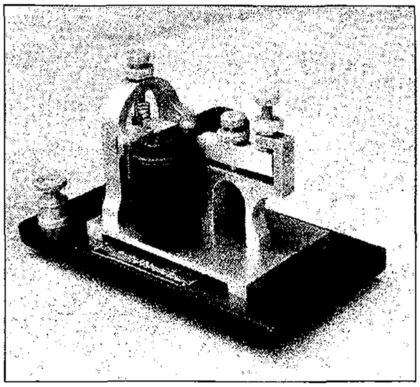

***Photo B.** The sounder as shown was used in telegraph offices beginning in the second half of the nineteenth century, and many were still in use through the 1930s.*

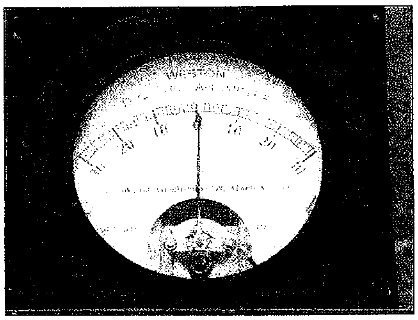

Photo C. *A modern version of the galvanometer. Used today as a laboratory instrument, its development was one of the earliest examples of converting an electrical current into mechanical motion.*

by one Dr. Jackson, a fellow passenger on a ship carrying Morse across the Atlantic in 1832. Morse had been traveling in Europe, purportedly trying to further his career as an artist. It is generally thought that until his trip back to the United States, Morse didn't know what a telegraph was—but by the time the ship docked, Morse had compiled fairly complete design notes which he subsequently used in building his first telegraph. Jackson, a chemistry professor and amateur electrical experimenter, would later claim the telegraph idea was his. One of the many mysteries of technology. I suppose there are other examples, but in researching the history of electrical communications, I was surprised by the number and the ferocity of the legal battles associated with it!

Morse, though well educated, always had a tough time earning a living, compounded by the burden of raising his children alone, his wife having died quite young. This, coupled with living an artist's life, made him quite familiar with tough times. Had he not known trouble, though, he might not have had the personal fortitude necessary to get through the many ordeals he would face during his telegraph system's initial development.

Things weren't going too well...

In 1835, Morse got a teaching post at the newly organized New York City University as a literature professor. This was fortunate because it allowed him access to some of the university's facilities, and he needed lots of space to set up his equipment and carry on experiments between classes. He also found access to resources and other help unique to a university's environment.

One such resource turned out to be Dr. Leonard Gale, a chemistry professor also at the university, and knowledgeable in electricity. Gale was familiar with the Daniell battery and convinced Morse to try using it. They were to form a lifelong friendship.

Gale also spotted deficiencies in Morse's electromagnet designs and provided him with information about Joseph Henry's earlier work. This lead to Morse's producing electromagnets with many more turns of wire than he had ever before used, resulting in much superior performance.

By 1837, Morse had several hundred feet of wire strung around the university halls enabling him to stage demonstrations and test various improvements. Also in 1837, news of Wheatstone's British telegraph patent was getting around, which prompted Morse to register his work with the US Patent Office.

Actually Morse had received a copy of a letter circulated a year or so earlier by the US Treasury seeking ideas for establishing a government telegraph system, and he replied with a description of his system, as it stood, in 1836. Responding as he did, at the time he did, was fortunate for Morse, as this letter would later be his strongest claim to patent rights for his system.

During Morse's tenure at the university, he staged several demonstrations of his system as new developments were added. During one such showing in 1837, a young man named Alfred Vail turned up. He was so impressed by the telegraph that he recruited the interest of his father, George Vail, owner of the Speedwell Iron Works in Morristown, New Jersey, a successful manufacturing business of the time.

Morse's partners

As a single parent on a meager university salary, Morse hadn't been able to invest much money or time in his telegraph. The Vails, on the other hand, had money—at least Alfred's father did, and they were willing to invest some in Morse's telegraph. Alfred also wasn't terribly busy at the time and had time to spend on it.

Besides money, Alfred Vail brought a good mechanical aptitude to the telegraph project, having acquired it hanging around his father's iron works. Morse's strengths lay more in the abstract: ideas, research, etc., and thus his equipment lacked both electrical and mechanical sophistication prior to Alfred's showing up.

With Alfred on the job, things began taking on a new look. By early 1838, the two men had perfected the system to the point where it was ready to come out of the laboratory.

They made good partners. One of the first innovations to come out of the Morse-Vail partnership was redesign of the receiver. They changed it such that the paper tape marker now moved vertically, up and down, thereby marking the paper with dots and dashes instead of the previous zigzag pattern. At this point, copying was still done by translating the marks from the tape after the entire message was received. This new receiver did make a click-click sound as it marked the paper tape, though.

Another significant improvement made during this time was replacement of Morse's old cam strip sending system with a "key." Morse's cam strip was akin to a teletype machine's punched paper tape and required that the message be composed prior to sending. The addition of a key allowed direct sending in real time.

From 1838 on, the Morse and Vail Partnership would endure. During this time, Morse also acknowledged his old university colleague, Dr. Leonard Gale, as partner because of Gale's earlier electrical contributions to the system. Morse also recognized Vail's father, George, as a partner, largely because of the money George spent on the project. Later, Morse would find other "partners" he didn't know he had!

A government partnership

While the Vails had deep pockets, estimated costs for building a test line, even over the relatively short distance of 50 to 100 miles, was more than they were willing to spend at the time.

Morse himself didn't have the money, and other investors were reluctant to invest because as yet, no one could see the telegraph as being economically viable. A telegraph, though now possible, was

largely regarded as somewhat of a novelty. Faced with this, Morse decided to turn to the government, and began trying to sell the Congress on funding the first line.

In February, 1838, having seen an impressive laboratory demonstration, a Congressional Committee recommended an appropriation bill to build an experimental line, but the bill failed to pass. For the next two years, the Morse system sat idle while Morse tried to raise money for the project.

During these two years, Morse traveled to Europe seeking foreign support. While there, he approached the English, French, Germans, and Russians in a futile attempt to obtain backing. As one account goes, he was rather badly received in England where Wheatstone was busy promoting his system, and as another story goes, he managed to alienate the Czar of Russia so completely that any mention of the Morse telegraph was banned in Russia. Morse fared no better anywhere else either—foreign diplomacy was not his calling. He didn't raise a dime!

Tail dragging, Morse returned to a rather interesting homecoming. Upon arrival in New York, he found he'd been sacked by the university, which was beset with hard times of its own. Professor Gale, his old friend and partner, was also affected and forced to find a new job out of town. Morse then learned he was being sued by good old Dr. Jackson over whose idea the telegraph really was. Finally, to completely round things out, Morse learned the Patent Office had issued Wheatstone the first US telegraph patent ahead of his own pending application.

Although things looked grim, Morse continued to lobby Congress to fund the project over the following three years. During this time, he was reduced to abject poverty, relying on tutoring art students to make ends meet. Finally, by March 3, 1843, the appropriation bill passed the legislature and was signed by President Tyler. Persistence had paid off at last!

"What hath God wrought?"

Morse had already given up hope for 1843, believing this legislative year had come and gone like those previous. Ann Ellsworth, young daughter of a Washington official, delivered the news of the appropriation bill's passage to Morse a day later. In gratitude, Morse promised her she could name the first message to be sent over the completed line.

The experimental line was to link Washington with Baltimore. Originally, Morse and company planned to bury the line underground due to fears over possible damage by the elements. Unfortunately, that failed after almost nine months of construction, when it was discovered the wire insulation used was inadequate. Switching gears, they started stringing wire on poles overland. On May 24, 1844, with Alfred Vail in Baltimore monitoring, Ann Ellsworth handed Morse her message. It was from the *Book of Numbers*, "What hath God wrought?" Morse personally tapped it out from Washington. Within minutes, Vail signaled back that he had the message and repeated it back over the line as proof the system worked.

The inauguration of the first operational link initially received a lot of attention in 1844, but there wasn't exactly a stampede of people wishing to send telegrams from Washington to Baltimore. It even took some time for the news media to recognize its value. With no immediate financial incentives for building additional telegraph circuits, Morse's system sat relatively unused for some time.

One of the early events to awaken public awareness of the telegraph's value occurred somewhat by chance. The Democratic National Convention happened to be held in Baltimore the summer of 1844, soon after startup of the new line. As one might expect, there was a lot of interest in Washington over what was going on in Baltimore. This interest heightened after James K. Polk received the Presidential nomination, a surprise—followed by a bigger one. Silas Wright was named the Vice-Presidential nominee, and he, upon hearing the news in Washington, announced he would refuse the nomination.

Morse sent a telegram to the convention in Baltimore with this news, but the conventioneers initially refused to accept the telegram's authenticity. After the message was in fact verified (by railroad dispatch), negotiations began, by telegraph, to resolve this nomination dilemma. It ended with the nomination of, and acceptance by, George M. Dallas to replace Wright. While this incident may seem a minor piece of historical trivia, it served to trigger a few key people to recognize the telegraph's potential.

Morse viewed the telegraph as a public utility and continued to operate the Washington-Baltimore line as a free service for a time, but Congress remained uninterested, and the system remained primarily a curiosity. At this point, the Post Office decided to fund the line as part of its operations, but after sustaining two years of losses (they charged 1/4 cent per word), the government got out of the telegraph business.

Earlier in Morse's Congressional lobbying days he'd met Francis O. J. Smith, then the Congressional Chairman of the Commerce Committee. Smith had, at that time, convinced Morse to give him a share of the telegraph system in exchange for Smith's peddling his influence to help raise money. Smith apparently didn't have the influence he thought he had because he was able to raise only dust, not money, during this time.

Smith had since left public life to become a promoter of sorts, probably a better career choice for him. Still claiming his part ownership in Morse's telegraph, however, Smith attempted to form a private company to build a line between New York and Boston. Unable to sell this idea initially, Smith turned to building a line from New York to Philadelphia, and by late 1845 had raised enough money to begin construction.

By early 1846, the line had reached the Hudson River at Newark. While the British had perfected submarine cable technology, Smith and company's cable was not capable and failed under water. This forced temporary use of a river-ferry relay in order to get the line operational by summer.

Near the end of July, 1846, the company began reporting "profits," thus touching off a wave of expansion. It should be noted that the actual profitability was dubious at best, but reporting profits sure made stock sales easy! By 1849, many lines were in and actually *were* making money, partially due to news service and railroad business. In time, Morse gained a fortune through expansions by Western Union and the American Telegraph Company, as did virtually everyone else associated with the telegraph.

By 1860 most of the Eastern US was linked by telegraph lines, and by 1865, the US was linked to Ireland and Europe by the Trans-Atlantic Cable.

NEVER SAY DIE

Continued from page 31

But what about all those hemophiliacs who've been dying of AIDS as a result of blood transfusions? It turns out that's tied in with a new drug for hemophilia called Factor VIII. This is an immuno-suppressive drug, so if the patient also is also HIV positive, the chances are that a doctor will prescribe FDA-approved AZT, and that's the end.

Maybe you've noticed that none of the AIDS establishment's frightening predictions have materialized. Our hospitals are not packed solid with people dying of AIDS. The big winners have been the condom manufacturers, Burroughs Wellcome Labs and their AZT sales, the AIDS support groups, and those benefiting from the billions of government money that Congress has thrown into fruitless research (welfare for scientists).

The Duesberg book is a fascinating (if long) detective story, and there is no shortage of bad guys put into the spotlight.

So then how are the Bioelectrifier and the Beck Blood Purifiers pulling so many people back from death? I suspect that by passing a tiny electrical current through the blood it prevents various viruses, microbes, fungi, yeasts and parasites from replicating, thus allowing the immune system to regain enough strength to fight off any number of illnesses which had gotten the upper hand. Like cancers.

And combined with the damage done to people's bodies and immune systems from long-term drug use (including nicotine and alcohol), there is the mutation of microbes which had previously been beaten back with antibiotics. In case you haven't read, most of our more serious invaders are now antibiotic resistant, and the rest are well on their way. This onslaught of infectious diseases also helps defeat the immune system. If you haven't read about it, the current estimates are that over 80,000 people died in 1996 in hospitals just from diseases contracted in those hospitals. That's right, not from the illnesses which brought them there, but from those contracted while there. A hospital is a very dangerous place to be.

I'm not sure whether that 80,000 is in addition to, or part of, the 300,000 deaths the Ralph Nader researchers attributed yearly to hospital errors—mostly errors in medication. I suspect it's in addition.

Dr. Fisher Disagrees

But not a whole lot. In *The Plague Makers*, Dr. Fisher presents a well-researched case targeting not only recreational drug use as knocking the immune system down, thus allowing the AIDS syndrome to happen, but he presents a solid case that the over-use of antibiotics by two specific groups, gay men and drug users, has significantly contributed to the destruction of their immune systems. Both gays and intravenous drug users are constantly having to fight off infections, hence their high use of antibiotics.

If I had any sort of immune systems related illness my first move would be to do everything known to get my immune system perking at peak efficiency. I'd follow the Comby book's raw food diet and change my eating habits immediately. I'd get those UVs into my eyeballs every day, per Dr. Douglass. I'd be out there briskly walking for several miles a day, rain or shine. I'd hyperventilate every hour or so to get more oxygen into my system. I'd make sure I was drinking at least eight glasses of distilled water a day. And I'd use the Bioelectrifier at least an hour or two a day. I would not take any prescription drugs (or other drugs, for that matter). I would make sure I was getting vitamins A, C, and E.

Scientists

A letter from Albert KE4HUD included a newspaper clipping to the effect that the job market is tight for scientists. Now, I'm a real big fan of science and believe that we have a serious need to get our kids interested in high-tech careers. But I don't think I've ever promoted the idea of anyone going on to become a scientist. In general, scientists tend to be a mile deep and an inch wide in their fields, wear lab coats and be super-nerds.

Looking at it from the career point of view, with very few exceptions scientists are never going to make much money. Job-wise they're heading toward one of two possible employment opportunities: working for a large corporation, or a university. Neither of these is ever likely to pay much except in prestige (oh, vanity).

The odds for making money these days lie in being an entrepreneur, and here a high-tech background can be worth zillions. Ask college dropouts Bill Gates or Steve Jobs.

The Gel Cell Storage Battery

A great little power supply.

Frank Brumbaugh KB4ZGC
P.O. Box 30, c/o Defendini
Salinas PR 00751-0030

The gel cell storage battery is the king of batteries both for portable operation and for emergency backup power in the ham shack. This type of battery has a great many advantages over other kinds.

Gel cell batteries are tightly sealed, so they can be stored, charged or discharged in any position with no danger of electrolyte leakage or outgassing. No maintenance is ever required.

These batteries are cost-effective, providing a high watt-hour per dollar value. They are widely available from a number of manufacturers and are low in cost, considering their power capability and usual life spans.

In normal use, the dependable service life of gel cell batteries is four to five years when used for standby use, and between 200 and more than 1,000 discharge/recharge cycles as a function of the amount of power delivered before recharging. Gel cell batteries do not have "memories" such as haunt NiCd batteries.

Gel cells possess a very high energy density, resulting in smaller physical size for the amount of power they offer. They are available in many sizes (from vest-pocket to hernia-inducing), and in voltages of 2, 4, 6, 12, and in some cases 24 and 28 volts. They can be connected in series for higher voltages, and/or in parallel for higher load current capacity.

Gel cell batteries can be charged over a temperature range of -20°C to +50°C (4°F to +122°F), and can be used to produce power from -40°C to 60°C (-40°F to +140°F).

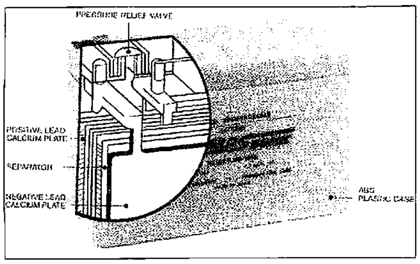

Fig. 1. Internal construction.

Although it's not recommended, gel cell batteries can be discharged much below the normal level (in an emergency), yet retain the capability of fully recovering when recharged. These batteries can also, in pulse type service, supply up to 10 times the ampere-hour capacity of the battery for these very brief pulse periods. Thus, smaller batteries can be used when very high peak current is required for very short time periods without damage.

Gel cell batteries are ideal for portable operation, especially for low power stations, and most QRP operators in this rapidly growing segment of ham radio use these efficient batteries to power their rigs when hiking, backpacking or camping. These batteries are an obvious choice for Field Day, and there are quite a few bicycle mobile stations using gel cell batteries for power.

The larger capacity batteries are most desirable for backup power in the home station, and are usually continually floated across the +13.8 VDC output of the station power supply. This keeps the battery fully charged and ready to supply power to the ham station should commercial power be lost.

Inside that neat plastic box

Fig. 1 illustrates the internal construction of a typical gel cell storage battery. Lead-calcium plates containing a small amount of tin are very strong, durable, and highly resistant to warping or damage due to excessively deep discharging. The electrolyte, a dilute sulfuric acid similar to that used in automobile and marine batteries, is locked into a gel almost like candle wax, keeping it constantly in contact with the plates.

Separators between positive and negative plates are usually made of porous Fiberglas™ cloth which is highly resistant to heat and oxidation. This cloth easily absorbs electrolyte, further stabilizing the battery.

Many gel cell batteries contain a pressure relief valve, as shown in **Fig. 1**. This comes into play *only* with excessive gas pressure caused by overcharging. It is a one-way valve and does not allow ambient air to enter the battery. With normal charging there will never be an occasion for this valve to operate. It is strictly a safety device for a worst-case situation.

The gases produced during charging—oxygen from positive plates and hydrogen from negative plates—combine to form water, which maintains the water content of the electrolyte at the proper level, making a truly "maintenance-free" battery.

The battery case is sealed both mechanically and with epoxy, plastic or hot seal to produce a liquid- and gas-tight container.

Battery capacity-discharging

Gel cell batteries are available with ampere-hour (Ah) capacities of 0.05 to 100 Ah, rated for a 20-hour discharge rate. Capacity in Ah, always expressed by the capital letter "C," is used when calculating or expressing the *rate* of charge or discharge. The Ah capacity of any battery is equivalent to C in all cases. This means that the number of Ah (C) discharged at a rate of 0.05 C, will discharge the battery fully in 20 hours. If the discharge rate is higher, for instance doubled to 0.1 C, the fully discharged state will be reached in just nine hours. Discharge rates are constant in this example, but would be reasonably accurate for average discharge current. These examples apply to all gel cell batteries, regardless of terminal voltage or Ah capacity.

As a concrete example, a battery of 2 Ah (C=2) will supply 130 mA for 20 hours, but if called upon to deliver 260 mA, the battery will be fully discharged in

nine hours. At the high drain of one ampere (C/2), this battery would be discharged in only one hour 20 minutes.

The fully discharged gel cell battery will produce a *per-cell* voltage of 1.75 volts. For a nominal 12 volt battery such as is used by most hams, this is a terminal voltage of 10.5 volts. Conversely, a fully-charged battery will have an open circuit voltage of 2.15 volts *per cell*, or 12.9 volts for a 12 volt battery.

It is best, if at all possible, to refrain from discharging a battery below 1.94 volts per cell. This amounts to 11.64 volts for a 12 volt battery. Because most ham transceivers either quit or operate poorly as the supply voltage sinks towards 11 volts this is not a hardship, and halting discharge current while battery voltage is above the fully discharged state will contribute greatly to overall battery life.

If you're interested in the gory details of discharge curves and more technical information that you'll probably need in this incarnation, ask a manufacturer for their literature.

In choosing a gel cell battery for portable operation, calculate the current your rig draws on receive, and if using CW or SSB, one-half of the peak current drawn on transmit.

Assuming you wish to operate a maximum of 20 hours before recharging your battery, your *average* current drain must not exceed 0.05 C. Preferably it should be less.

Because most operating time is spent tuning and listening on receive and only a small amount of time is spent actually transmitting, unless you're as long-winded as I, a simple way is to calculate the current in Ah used during a one-hour period, with perhaps 50 minutes receive and 10 minutes transmit.

Calculate 5/6 of receive current drain. Then calculate 1/6 of *peak* transmit current drain and divide this by two because the intermittent nature of CW and SSB can be construed as a 50% duty cycle. Then add the two final calculated values together. The sum is your average current drain in amperes for one hour of operation.

A real life example: I have a 12 Ah gel cell (C=12) which powers a QRP-plus transceiver. Receive current is about 0.2 A, and half the 1.5 A peak transmit current is 0.75 A. Taking 5/6 of 0.2 A, which equals 0.167 A (rounded off), and 1/6 of 0.75 A, which equals 0.125 A, and adding these values together gives a total *average* current drain of 0.292 Ah *per hour*.

The 20-hour discharge curve shows that 0.05 C is 0.6 A for this battery. A simple ratio calculation is: .6 : .05 = .292 : x; .6x = .0146; x = .024.

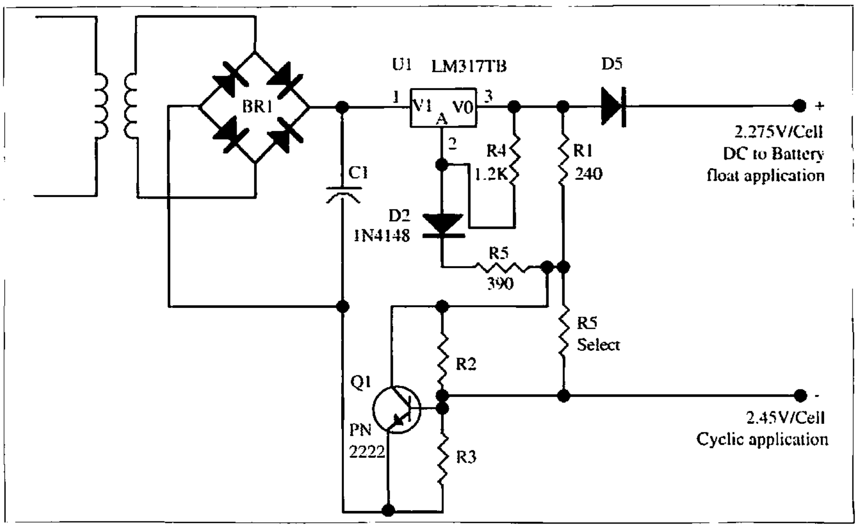

Fig. 2. Constant current/constant voltage charge circuit.

Thus, in this case, the average current drain is equal to 0.024 C, about half of 0.05 C, so the 12 Ah battery will allow about 40 hours of operation before having to be recharged.

Using a calculator, it is much simpler to calculate the ratio with the decimal fractions rather than first converting them to powers of 10 as is customary.

Charging the battery

A new gel cell battery, although fully charged by the manufacturer, needs a bit of exercise to develop its full capacity. This can be accomplished either by floating the battery across the station power supply for a couple months. This is simplest if it is a backup battery for the home station; or has been used for a while, undergoing a number of charge/discharge cycles.

A voltage somewhat higher than 2.15 volts *per cell* (12.9 volts for a 12 volt battery) must be applied across the battery terminals. After discharge, and after charging, the terminal voltage may be temporarily lower or higher, respectively, but in a short while it should stabilize at the 2.15 volt per cell level.

The best charging method recommended for gel cell batteries is the "constant voltage, constant current" arrangement. This will ensure maximum battery life and capacity while not requiring excessive charging time. However, the charging current must be so limited that it cannot exceed 0.25 C, or 1 ampere for a 4 Ah battery, for instance. *This is most important to prevent damage to the battery!*

A large capacity gel cell battery used in float service as backup power for the home station is never discharged very deeply, and recharging requires a *lower* maximum voltage for charging.

Caution: In all cases the charge current must never be allowed to exceed 0.25 C or the battery could be damaged.

The recommended float voltage is 2.25 to 2.3 volts per cell, or 13.5 to 13.8 volts for a 12-volt gel cell battery. This allows the battery to be connected permanently across the output terminals of the standard 13.8 volt station power supply. If the home station is used at least weekly, the standby battery will never need charging unless it has been used in an emergency to power the station.

Constant voltage/constant current charger

Fig. 2 illustrates a simple charging circuit suitable for the small gel cell batteries normally used for portable operation. Because a heat-sinked 317T regulator is used, the maximum current is limited to one ampere. RS is chosen to provide the proper minimum float voltage (0.6/R3 = max).

R2 and R3 are determined by the level of filtered DC voltage available and the maximum current (0.25C or lower) to be applied to the partially or fully discharged battery. They will have to be determined empirically.

The manufacturer of your gel cell battery will usually recommend a charging circuit for your application if you list your expected average and peak current drain and the acceptable discharge terminal voltage when you write. He not only wants your battery to provide efficient service but he also wants to sell you a replacement battery when the time eventually arrives.

NEVER SAY DIE

Continued from page 40

And the way the world is going, the big money is going to be in high-tech businesses for a long time to come.

It is unfortunate that around 95% (or more) of hams memorize the Q&A manuals to get their tickets and the learning process stops soon after. Here's a hobby that offers a world of learning opportunities, with it being fun every inch of the way. But yes, it does take some determination and perseverance to learn about radio, microwaves, digital communications, and so on. And yes, our blessed school system spends K-12 at a minimum doing its best to kill whatever sparks of motivation might have been inherited genetically. Grumble.

Fluorides. Again.

Are you still drinking tap water? What does it take to get you to get a small still and start distilling that sewage your city or town is providing? You don't need any of the toxic metals that come out of your spigots. Worse, you surely don't want to put chlorine into your body, and the chances are that your water system has plenty of that poison.

But the most damaging of all the water additives are fluorides. Oh, there goes Wayne, on some sort of an ecological kick. Oh yeah? If you send me an SASE I'll send you a copy of the results of 30 research lab reports of genetic damage caused by fluorides, plus a list of 35 published peer-reviewed papers attesting to the genetic damage. These research reports show clearly that as little as one part per million of fluorides in drinking water causes measurable genetic defects in sperm chromosomes, and that means some sort of genetic defect will be passed along to your children. And this is not going to be helpful. This can mean small or large birth defects, none beneficial. And these will, in turn, be passed along to your grandchildren. That what you want?

I started out buying gallon bottles of distilled water from the drug store, then Pat Flannagan mentioned an inexpensive still available from Damark. I invested in a Genesis unit, which cost under $200. Works like a charm and has paid for itself many times.

The Dr. Yiamouyiannis book, *Fluoride, the Aging Factor*, which I've reviewed in my editorial, and is on my list of books you're crazy if you don't read, has the subtitle, "How to recognize and avoid the devastating effects of fluoride."

You've read about the decreasing sperm count in American men. Well, fluoride in the water supply has been shown to do this. It's a deadly poison, and helps knock the stuffing out of your immune system.

Do It Yourself!

Put yourself in my chair—well, walk a mile in my moccasins, is the cliché. Suppose you were writing an editorial every month,

Number 44 on your Feedback card

The Ten-Tec T-Kit 1208 6 Meter Transverter

Here's a fine introduction to modern kit-building.

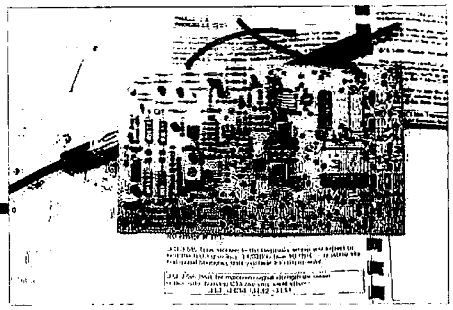

Photo A. The T-Kit 1208. (Photo by NØBLX.)

Peter A. Bergman NØBLX
3517 Estate Dr SW
Brainerd MN 56401

A converter allows your receiver to tune a band for which it was not originally designed. A *transverter* allows your transceiver to receive *and transmit* on a band for which it was not originally designed, by subtracting or adding a local oscillator frequency—in this case, 36 megahertz—from or to the displayed frequency on your transceiver. This gives you access to the added band with all of the wonderful features already present in your expensive HF rig, without spending piles of money.

Suppose your license does not allow you to transmit on the 20 meter band? This is not a problem because you aren't transmitting on 20. Instead, you are using your 20 meter transceiver as a tunable IF stage to control the transverter on 6 meters. If your HF rig will only transceive from 14 to 14.35 megahertz that's still not a problem since a lot of the action is between 50.0 and 50.35 anyway. Receive coverage up to 18 MHz lets you monitor the rest of the 6 meter band.

If you've never built a kit...

Despite some things you may hear about the "Golden Age" of kits, modern kits are great, and when you get a kit from an outfit like Ten-Tec you can durn near write off the cost as tech-school tuition. Add in entertainment value and the satisfaction of a working unit you built yourself and you're way ahead.

Okay, you are thinking about ordering the T-Kit 1208, but what do you need up front? First, a 20 meter transceiver capable of being adjusted to 5 watts output reliably. Second, a regulated, well-filtered 12-15 volt DC power supply capable of about 4 amps. Third, some kind of 6 meter antenna. A dipole will do for starters. And, a 52 ohm dual PL-259 jumper to connect the rig to your new transverter.

Tools? You will need a 15 to 35 watt soldering pencil and thin-diameter rosin core solder. This is a must. Thin-diameter. Rosin core. You will also need diagonal cutters—small ones—and needle-nose pliers, ditto. I like to keep a pair of locking forceps handy. They make great heat sinks while soldering and are useful in many other ways. According to the T-1208 manual, the coils can be wound on a .313" X-acto™ knife handle or a clean 3/8" bolt (that's what I used). The book also said you'll need a wire stripper. That's what I used the X-acto knife for. Alignment tool. Do not try using metal hex wrenches, screwdrivers, etc., as alignment tools. If you don't have any yet go to Radio Shack™ and get their 64-2220B set. I also like to keep a sharpened dental pick on my workbench. It is very useful for clearing holes I soldered shut accidentally, and for unbraiding coax. A 2- or 3-inch paintbrush is also useful for cleaning up.

Test equipment

You've got to have a volt-ohmmeter for this project, and once you get one you'll use it for years. There are some inexpensive digitals available but the better quality you start with the happier you will be with it. I know that a lot of you have tons of test gear but I'm talking to the folks who are just getting started in this great hobby. You will also have to have an accurate RF wattmeter that has a 10 watt scale or slug. If you have a cheapie from your CB days find someone with a Bird to check it for you. Then you can make a correction chart for yours.

Optional test equipment includes a frequency counter and an RF signal generator. I used my MFJ™ antenna analyzer for both jobs. For a second piece of test gear—after the VOM—I'd say that a 249 or 259 from MFJ is hard to beat.

Start your kit

The parts are packed neatly by type in separate bags but let's leave them alone for a while and take a look at the instruction manual.

Kit builders seem to fall into two categories: those who read and follow the directions and those who don't. I try to stick with the former group. More of my projects work that way.

The 1208 manual contains about 80 pages; the print is clear and the text and drawings are concise. A tip of my hat goes to Ten-Tec and Dan Onley K4ZRA who did the writing.

On Assembly page 48 is an important notice about driver transmitter power. Although there are several notices in the manual which tell you that the 1208 was designed to use a 5 watt input, it also explains that changing the value of R5 will allow inputs from .25 watts to 8 or even 10 watts.

It seems to be a fact of life that however well the manual is written there are always some addendum sheets. Go through them carefully and make any needed changes to the manual before starting construction. I

like to run copies of both sides of the addendum sheets and cut and paste them in the appropriate places in the book.

Even if you have built kabillions of devices, and especially if you have not, read the theory section. It will help you understand what you are doing and will explain why the designers made the decisions they did. After that, do the parts inventory.

Each of the seven assembly phases includes a schematic and board layout diagram of that phase, which is very helpful. Phase 1 is preceded by a "dos and don'ts" page so that is a good place to start actual assembly. Somewhere in your collection of baggies is a tiny ferrite bead—about the size of a mustard seed. Following "do 1" install that bead now. That way you won't have to worry about where the little rascal went later after you have been chasing the other parts around for a while.

The first page of construction is board preparation, installing "vias," which ensure that the upper and lower ground planes are tied together. You will also install a few test points and fabricate the test plug. A word of warning to the uninitiated: The test plug requires a 1/4 watt 150 ohm resistor, not the 3/4 watt you will be wanting later.

Another word of warning: I don't care how much money your mother makes or who your dad knows or how big your brother is, please, never, never carry molten solder to the joint on the tip of your soldering pencil. The actual amount of solder you'd have to spill on the board to create hair-pulling problems is infinitesimal. Instead, heat the joint with the tip of the soldering pencil and apply the solder to the other side of the joint. The solder will melt and flow towards the heat and if everything is nice and clean—as it probably is—you will produce a nice, shiny, conductive joint that will stay that way for years.

Yet another warning: Don't use steel wool to wipe off the tip of the soldering pencil. Sure, it does a great job but you will probably have tiny wild hairs of wire all over the place.

If you follow the manual's directions you will not get the 3.3 μH inductor mixed up with the 3.3 ohm resistor. The resistor goes over near where you'll install Q11 later. Handle these small inductors carefully, especially when bending the leads; I managed to torque one in half. T-Kit sent me a replacement as soon as I called, but it's embarrassing and stops production.

Observe polarity—orientation—on all semiconductors and electrolytic capacitors. Every time. I go so far as to install the resistors so the color-code reads the same way. It helps keep me in the habit of paying attention to the orientation and later it might help during troubleshooting. Looks neater too. When installing disk capacitors I try to install them so that I'll be able to read the value code easily after the surrounding components have been installed.

Double-check your work.

We're having fun now

Now comes one of the really fun parts—the Phase 1 progress test. Unlike the "Good Old Days" modern kits like this one are designed to be assembled in functional stages so that each stage can be tested with power on. This way, as you progress through assembly you know you left good stuff behind you. If you skip the progress checks and run into problems later you'll have to go through the entire device to figure out why. Minimum test equipment is an FM broadcast receiver tuned to 108 MHz. Got one, right?

> ***"Using just an indoor dipole antenna, I could hear stations all up and down the East Coast clear into Canada from my home in Minnesota. What a gas!"***

The easiest way I found to perform the Phase 2 progress test was to use a coax adapter on my 4-5 watt 2 meter rig. If you use a transmitter capable of more power make absolutely sure that the output is reduced to 5 watts.

No matter how you feel about progress tests, make sure the TR circuitry works at this point.

There are at least two reminders to make sure that J2 is securely soldered to the top ground plane. Read and heed.

Follow T-Kit's suggestion about putting a spacer between the coil and the board while soldering. You definitely do not want the coil touching the ground plane at any point.

While installing Q15 you may wonder why the designer didn't have you do that before you soldered all those other parts around its space. All the heat you were pouring into the board in that area would not have done the transistor any good. The same is true of the rest of the semiconductors on the board.

When bending the leads on Q15 hold the lead with the tip of your needle-nose pliers next to the transistor body. Work carefully and make sure to bend the leads so they all slide easily through the mounting holes. If you just sort of line them up and pull from the other side of the board you may create enough strain to break the transistor.

As luck would have it, when I got to the Phase 3 alignment test the band was wide open and, using just an indoor dipole antenna, I could hear stations all up and down the East Coast clear into Canada from my home in Minnesota. What a gas!

During these power-on tests and adjustments you will really be glad you took your time and got everything to work as you went along instead of slapping things together and hoping for the best.

I deviated a bit from the order in which the steps are presented in the manual. At one time or another I've worked on everything from typewriters to bulldozers so I have a feel for how I want things to go together. For example, I found it easier to rearrange the steps so that I worked from the bottom to the top when wiring the switches and from left to right when wiring the SO239s.

Make absolutely sure you adjust the lengths of the coaxial cables so that they can be bundled neatly per the instructions. If they are just strung randomly across the board all sorts of unpredictable things can happen. Also, watch what you are doing when cutting the coax. Somehow I ended up with two inches in my hand that needed to be in the kit. Fortunately I had some in the junk box.

Final alignment

You had the receiver working, transmit bias adjusted and reasonable RF output before you installed the board in the case, right? If everything is working to your satisfaction, you are just about finished. You might want to find a spot inside the case to store the test plug, as I did.

The fun of building has actually just started for you because every time you sit down to work you'll know you built it yourself. Have fun on the "magic band" and 73s.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

Every February I get this image, somewhere, of a ham poking his head up and looking around, like the groundhog on February 2nd. But unlike the groundhog, who is looking for his shadow and in that search judging the coming weather, our amateur buddy is looking for software to enable entry into the digital universe.

The questions I receive reflect the great diversity of that quest. Bob Rushby VE3GLA sent along a note saying:

"I've been active on RTTY for some time with a MFJ-1278. Recently, I got the chance to buy an old HAL ST-6000 for a very good price. I'd heard great things about how well it works in weak signal conditions, so I bought it.

"My big problem now is what is the best terminal emulation to use with the ST-6000. The 6000 has 5-bit Baudot i/o, so normal terminal emulations that use ASCII aren't much use. I spent some time surfing the net to find something, but everything I find is for more modern devices like the MFJ, the KAM, etc."

Any suggestions?

Bob, while it may look like you have come up against planned obsolescence, those of us who grew up using World War II equipment 20 or 30 years after the fact know that such does not exist in amateur radio. That HAL demodulator is a fine unit, and should do just fine in service once again. One program to start with is TRTY, which is on the first disk of the RTTY Loop Software Collection. At the end of this column, I'll detail how to obtain these programs.

This program is an MS-DOS-based RTTY program which can also handle packet with a TNC. With a plain terminal unit, the HAL series being prime examples, this program should perform admirably to enable both ASCII and Baudot communication. I would be interested in hearing how well this works out for you on the air.

Of course, if you have a multimode controller, there is always a question about that one. Greg N8TDL writes:

"I have a PK232. What is the best software to buy for Windows 95?"

Along with the XPWare software discussed last month, you might take a look at the newest version of PaketPet. Now in version 3.2, this program from Chuck Harrington runs under Windows 3.1, 95, and NT; along with OS/2, and virtually all hardware TNCs, including the PK-232. Chuck passes along some of the following features:

"Point & Click Interface to Packet Mailboxes. Mail Window passively collects message headers, then left click to read, right to reply! Automatically log mail/traffic sent! Automatically format message line length, insert signature file, spellcheck and send! Integrated 90,000 word Spelling Checker. Three integrated text editors. Signature/Forms files supported. Restartable Yapp and text file transfers supported.

"TNC Settings Editor Dialog Box to display/edit your TNC's settings! ANSI color graphics and sound support. Written in high performance C language. Integrated database listbox to save your packet/Internet addresses."

Fig. 1 shows the display of PaketPet, with many of the features enabled. You can get a copy of the program via the RTTY Loop Download Page, or on Chuck Harrington's page at:

http://www.gate.net/~paketpet/

Either way, having obtained the shareware version, registration to a full package is easy and quick.

When it comes to checking on the RTTY Loop Home Page, pay attention to the details, please! I won't name names, to spare anyone embarrassment, but I received an E-mail saying:

"I'm not having any luck with the web URL that goes like this:

www:2.ari.net/ajr/rtty/

"Got it from a friend of mine and maybe he looked at it without his glasses on! I'm a born again RTTY nut from the old days, I am afraid to say. I like the smell of my 28 machine running. I am interested in any DOS type software for my PC and web pages or reflectors on the subject.

"I guess I need to get off my butt and subscribe to *73* again. Did for over 20 years and then stopped with a job change several years ago. I am just now settled down and getting back in the swing."

Last things first: Yes, by all means, subscribe to *73!* There are no other amateur magazines on the cutting edge, with the freshness, or with this column; not to mention old Never Say Die! As soon as you finish reading this column, rip out that subscription card and mail it in.

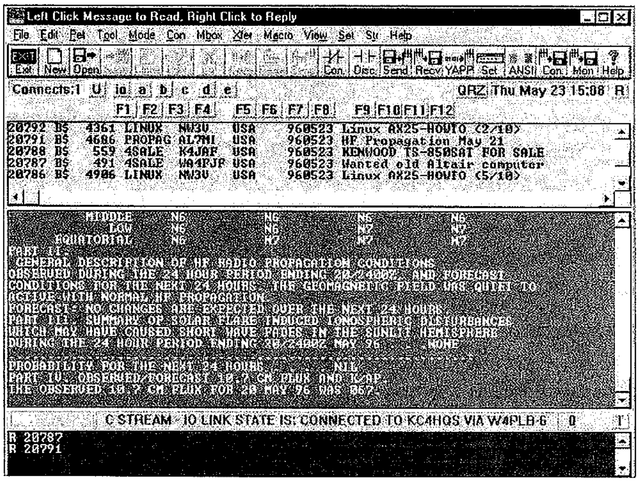

Fig. 1. PaketPet display.

As to the website address, this shows just how critical these things are. There is a colon in there that does not belong. The correct address, with the http: prefix, is:

http://www2.ari.net/ajr/rtty/

Another thing to note in many web addresses is case. With the Unix conventions used on the Internet, upper and lower case are different. In this case, "RTTY" and "rtty" are different, as would be "Software.html" and "software.html." Be careful, and type web addresses exactly as given!

Once you find the page, though, you will find a library of old "RTTY Loop" columns, many links to a variety of amateur radio websites, programs to download, and a listing of all the software available in the RTTY Loop Software Collection. Now, all of the programs in the collection are not online, primarily because I do not have enough space on my web server to put all 20+ Mb of programs up there. I do link to those available online, elsewhere, though, and have put several up in rotation that many have requested. I also can E-mail individual programs as requested by individuals. But, if you want to get the collection, or parts of it, which now numbers over a dozen disks, the simplest way is to either download the index listing, or, if you are not online, send a self-addressed, stamped envelope to the above address and I'll send you a copy of the listing. Then, decide on which disks you want, and send me a 3.5 inch, high density blank disk, US $2, and a stamped, self-addressed disk mailer for each collection desired. So, for five of the disks, you would send five disks, $10, and a mailer or mailers with postage and capacity sufficient to return the materials to you.

As well as providing a source of programs, I look forward to your comments, questions, criticisms and suggestions. Please send them to me via snailmail at the above address, or electronically at ajr@ari.net, MarcWA3AJR on AOL, or 75036,2501 on CompuServe.

Carr's Corner

Falls Church VA 22041

Better Ham Software Design? Please?

The only reason I don't refer to myself as a computer geek is that I know the definition of geek (it's a carnival sideshow performer whose act involves biting the heads off small rodents or snakes ... look it up, it's in the dictionary). But I do like computers and computer software. I even teach a class in Visual-Basic 4.0 at our local community college.

What I don't like, however, is computer software that is poorly designed, or which has a poor user interface. And that includes a relatively large percentage of the software written for amateur radio and other radio hobbies.

DOS, by gosh, you're kidding, of course

One pet peeve is MS-DOS software that hasn't been upgraded to Windows yet. Several mini-NEC based antenna design programs, and at least two ionospheric propagation programs, on the market are DOS software. The problem is that DOS software often will not run on Windows machines. As you add software in Windows, it starts taking up space in the lower 640K of memory where DOS resides. If the DOS program is larger than the remaining memory available in the lower 640K, then it won't run (an "out of memory" error is generated).

I've discussed that problem in this column before. The solution is to either use a secondary configuration (as allowed in DOS 6.22) or create your own secondary configuration by messing with substitute config.sys files. But who wants to go to that bother? I want to see an icon on the screen that connects me to my radio program. Double-click it and go. What I don't want to do is mess with multiple configurations of my computer.

Today, the availability of Visual Basic and Visual C makes it too easy to develop Windows programs for there to be any excuse for selling DOS products.

Interface design problems

Even when people design Windows-based software for hams there is often a profound lack of skill demonstrated by the developer. One of the first things I notice is the human computer interface (HCI). I received one product from a small developer that I declined to review in this column because it was so poorly done. Some defects were obvious (like the hideous background color and the fact that he used a pastel that did not permit clear viewing of the eight-point typefont selected), but others take either a practiced eye or one use of the program (then the defects became really apparent).

> ***"I want to see an icon on the screen that connects me to my radio program; I don't want to mess with multiple configurations of my computer."***

That program was written in Visual Basic 3.00 (I could tell because the compressed file VBRUN300.DL_ was present on the distribution diskette—it's the run-time engine for VB 3.0). The program asks the user to input certain data in textbox format, and then it would calculate some neat smoke about antennas for you. Wonderful. It even worked.

But the author of the program did not realize that, unless he intentionally changes the order, the first command button laid down on the screen at design time is the one that receives focus when the program executes. Focus means that the button is outlined in darker grey, and will respond as if the mouse was clicked on it by pressing the <ENTER> key on the keyboard. If a command button receives focus like that, then it should be the command button that initiates the preferred default action. Instead, he focused his EXIT button. So, when a number is entered into the textbox, the natural thing for a user to do is hit <ENTER> rather than <TAB> as he intended. So what happens? The computer terminates the program. Sighhhhhhh.

Two errors were made in that program interface: 1) setting focus to a control you did not want, and 2) not using the <ENTER> key to navigate from one input textbox to the next. The <TAB> key does not automatically spring to mind when using the program like the <ENTER> key does.

Another gripe came from a program that was obviously written in Visual Basic 4.00 (again, the run-time *.DLL file was present). That program used textboxes to display calculated data (which is fine). The problem was that the author did not lock the display-only textboxes. This means that the textboxes could be altered by the user even though the program did not call for it. In VB 3.00 one had to manipulate the Windows API to lock textboxes, but in VB 4.00 it's a simple matter of checking the Locked property as TRUE ... so there's no excuse not to lock the box.

I've also seen problems in programs that cause the thing to bomb out. For example, one program from a source in the UK allows the user to go forward to the next step even if the current step is incorrect. This program calculated the length of antenna elements given certain input parameters. One of the parameters was frequency of operation (F). If a user enters 7150 for the frequency in kilohertz (a legal entry in that program), then the correct answer is produced. But if the user accidentally enters 71t0 by striking the t key rather than 5, then the resulting numerical value becomes zero when the program does its calculations. Guess what that does when F is in the denominator? A divide-by-zero error terminates the program.

The correct way to handle that situation is to provide a means for preventing the user from going forward until the correct entry is made in each inputbox or textbox used for input gathering. Several approaches to this problem are available, so there's no excuse not to do it.

Also, error-handling code should be built into the software in order to trap as many errors as possible. The program might have to terminate gracefully (rather than bomb out), or the error might be user correctable (like entering a valid number for F). Error handling is part of good programming, but seems lacking in much ham software.

User interfaces for programs are what the user sees on the screen. These should be designed according to the UFA principle: Usability, Functionality, and Aesthetic. Usability means that the user can learn to use the program very rapidly. To the maximum extent possible, the operation of the program should be self-explanatory. Functionality means that everything the user needs is available on the screen, or can be reached with simple navigation through screens and menus. It also means that two functional items, or bits of information, that are needed at the same time should be on the same screen. Getting lost in the menu structure should not be possible. The aesthetics of the interface come dead last, but that does not mean that they are unimportant. The screen should be pleasing to view by most people (and that includes using neutral colors), and should be well laid out.

Wherever possible, the standard Windows approach to screen design should be followed. Have you noticed that a lot of Windows application programs look and operate similarly, even though they do completely different things? An advantage of following the usual designs is that the user finds it easier to intuit how the program works. After all, when he or she sees File in the left-hand corner of the Menu Bar, it is obvious what will be found there, and those items should always work the same as in other Windows-based programs.

Color usage

Color pollution is the best label I can think of for many programs I've seen. Color should be used wisely and sparingly on a screen. Color can reasonably be used to divide the screen into different task areas or different types of data. But too many colors on a screen increases the visual search time required to figure out what to do, and where that function is on the screen. Also, research shows that extensive use of color works better for experienced users of a program than for novice users. So design according to the intended level of the user community.

Programmers, by the way, make lousy testers. Even if they are the smartest people around, they are also too close to the project and too knowledgeable about computers in general to make a typical user. If you develop software for hams or SWLs, then have some of them (who are not geeks in either sense of the word) test it for you.

Consistency

Software programs should operate not only consistent with other Windows programs, and other applications of similar type, but they should also be internally consistent. Internal consistency goes two ways.

First, the user should see the same result from the same action every time it is initiated. Further, every time a follow-on repeat of an action is required it should be done in the same manner as in previous attempts (e.g. entering the frequency should not be done in a textbox one time and an inputbox the next).

Second, the system should respond the same way to user inputs every time they are made. In teaching the Visual Basic class I noticed several students who would fail to clear variables and certain input features, and so would create errors because the system thought that something else was intended. Computers are terribly ignorant; they do exactly, precisely what you tell them to do (not what you intended them to do, which may be different).

One good approach to design is to use what the HCI textbooks call forcing functions. These are design features that prevent the program from continuing further until the user input error is corrected. Examples of forcing functions fall into four groups:

Gagging. Prevent incorrect input by using strategies such as keyboard lockout or numeric-only checkers.

Warning. Display a message box or warning label when an error is made. Message boxes should include a suitable set of alternative actions that correct the error.

Do Nothing. This strategy keeps the program from doing anything further until the error is corrected.

Self-Correction. When an error is made the program detects and corrects the error, relying on default values. This may be the most dangerous approach because you may have to correctly guess which defaults are the ones intended.

Mea culpa

I don't want to hold myself out as a supreme expert on software or interface design, or somehow better than others. I've made most of these errors myself—but I've also learned. My software is not perfect, by any means, but at least I've learned these lessons ... and recommend them to others.

Conclusion

Sorry to dump on you folks with my pet peeve this month, but it is an irritant that I suspect afflicts many users of ham radio software (indeed, all software). Good design will make a product look, feel and work better. A lot more can be said about the subject, but I've used up my allotment of space for this time. Perhaps sometime in the future we will return to it. Perhaps. But if the makers of ham radio software get the message, then it won't be necessary. Just remember one thing: The amateur in Amateur Radio only means we do radio for fun, not for money. That does not imply that amateurish products are acceptable in our marketplace. Amen?

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

The AMSAT Annual Meeting

The 1996 AMSAT Annual Meeting and Space Symposium was held November 8-10 in Tucson, Arizona. Over 250 satellite enthusiasts listened to dozens of presentations and visited the Kitt Peak National Observatory and National Solar Observatory. For all participants it was a fantastic weekend. With the launch of the largest and most complex amateur satellite only months away, the symposium focus was on the status of the Phase 3D project.

Friday

This year the AMSAT Space Symposium began Friday morning with a presentation by Dr. Helen Reed, Director of the ASUSat lab. ASUSat stands for the Arizona State University Satellite. Work is underway to build a 10-pound satellite to be launched as a piggyback payload on a Pegasus rocket. The satellite is designed to carry a GPS (Global Positioning System) receiver, an earth-imaging experiment and a Mode "J" (2 meters up and 70 cm down) analog and digital transponder system. Launch is scheduled for spring 1997.

SEDSAT Project Manager Dennis Wingo KD4ETA brought everyone up to date on the status of the SEDSAT program. SEDSAT-1 is a microsat-class satellite that will be part of NASA's Small Expendable Deployer System (SEDS). Changes in launch schedules have caused delays with this hamsat. SEDSAT will carry several scientific and amateur radio experiments. The SEDSAT program also has a World Wide Web home page at the URL (Universal Resources Locator), http://seds.lpl.arizona.edu.

John Franke WA4WDL described a fascinating hardware project. John's interest in the Russian Tsikada (pronounced Cicada, like the insect) navigation satellites led to efforts to decode their telemetry signals. He built a dedicated "black box" to decode the 150 MHz FM signals from the satellites and display the time data.

Peter Vekinis KC1QF wrote a paper and made a presentation describing changes to his proposed "Picosat System" of low-earth-orbit amateur satellites. Peter proposes a constellation of Picosats all using VHF and UHF frequencies. Like the Motorola Iridium system of "cellular phone" satellites, the Picosats are to use inter-satellite radio links to extend the communications range.

This year's SAREX (Shuttle Amateur Radio EXperiment) talk by Frank Bauer KA3HDO focused on a new program, the Amateur Radio International Space Station (ARISS). Due to the long-term nature of the presence of an in-orbit ham station and the multinational use of the equipment, there are frequency coordination issues and operational aspects to be considered. National groups currently involved include Canada, France, Germany, Great Britain, Italy, Japan, Russia and the United

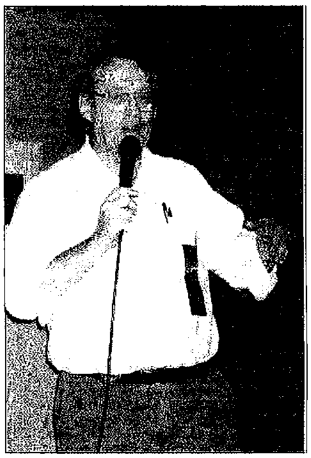

***Photo A.** Dr. Tom Clark W3IWI discussed many topics, including his "Totally Accurate Clock" and the problems with Mexico OSCAR 30.*

States. Goals include organization of all amateur radio manned space flight efforts, support, maintenance and upgrade of current *Mir* and Shuttle amateur radio gear, and the establishment of a single integrated radio system for the International Space Station.

Assi Friedman 4Z7ABA provided the gathering with an update on the Techsat-1 program in Israel. The first Techsat satellite was destroyed due to a launch failure in Russia in 1995. The new version of Techsat is similar to the first with a few upgrades for better digital store-and-forward operation. Two have been built. One will be launched early this year. More information about the family of Techsats can be found on the Internet at the URL http://www.technion.ac.il/~asronen/techsat/.

Other Friday afternoon talks included Gould Smith WA4SXM's description of the activities between the European Space Agency and AMSAT, an explanation of "what it takes" to set up and calibrate a radio telescope for SETI (Search for Extraterrestrial Intelligence), a reception by Dr. Paul Shuch N6TX and a tutorial on spread-spectrum techniques by Phil Karn KA9Q. Phil also presented material on Saturday concerning a high-performance satellite modem.

After dinner the talks continued but with a focus on newcomer topics. Barry Baines WD4ASW got things started with a general tutorial, while Ken Ernandes N2WWD discussed the fundamentals of Keplerian elements. The evening concluded around 10 p.m. with Doug Quagliana KA2UPW and his simple, yet effective, mobile low-power station description. Doug brought along some of his antennas and gear to show the attendees.

Saturday

Activities began in earnest at 8 a.m. AMSAT President Bill Tynan W3XO gave an official welcome to the symposium participants. Dick Daniels W4PUJ got things started with a Phase 3D construction update. The satellite is in the final stages of integration in the Orlando (Florida) lab. Launch is scheduled for April on the second Ariane 5 rocket from the Kourou, French Guiana, facility. All of the major components are in place and ready to go, with only a few exceptions. Work will continue at an accelerated pace to get everything ready and tested by the end of February.

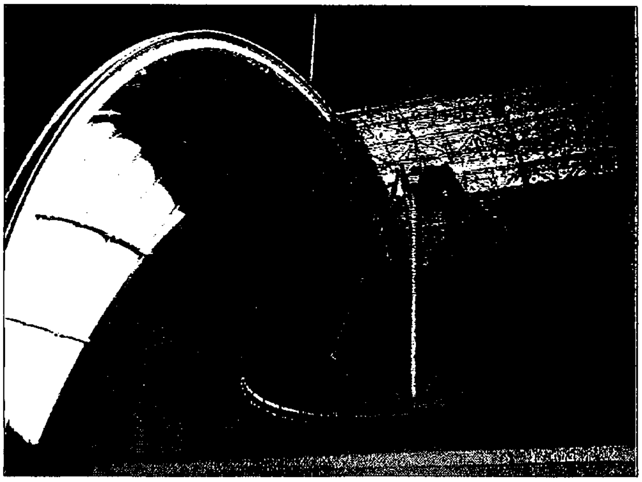

Photo B. *Most symposium attendees went on the Kitt Peak tour. This 12 meter dish at the National Radio Astronomy Observatory has been used above 300 GHz.*

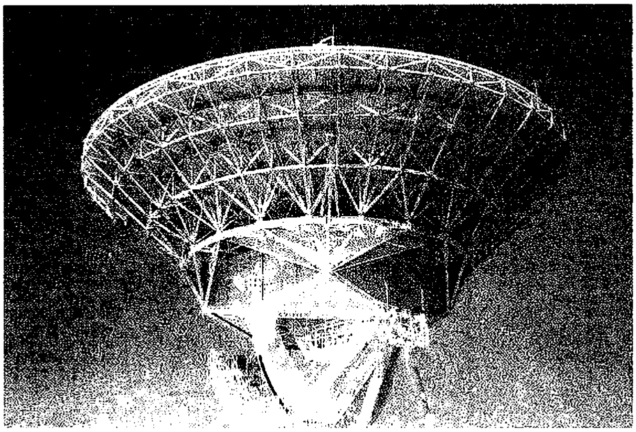

Photo C. The 75 meter dish at Kitt Peak is part of the Very Long Baseline Array (VLBA) network of radio telescopes. Those on the tour got a close-in look at all of the systems. The dish is used at frequencies up to 47 GHz.

Bdale Garbee N3EUA has been working on the Phase 3D GPS (Global Positioning System) receiver system. The original design has been scrapped and two new GPS receivers are being provided by NASA at the Goddard Space Flight Center. The purpose of the GPS receivers is to determine the viability of using GPS for orbit and attitude determination at orbits above the GPS constellation.

An update on the digital systems of Phase 3D was provided by Chuck Green NØADI. The system is called RUDAK. This is a German acronym for *Renerativer Umsetzer fur Digitale Amateurfunk Kommunikation.* This roughly translates to Regenerative Transponder for Digital Amateur Radio Communication. The program has a long history from its beginnings over a decade ago in Munich, Germany. The latest version will start its operational life as an orbiting packet-based digital communications system. Later in the mission it will be reprogrammed for new and faster digital modes. Development for this new version of RUDAK has been based in Tucson, Arizona, and includes many members of TAPR (Tucson Amateur Packet Radio Corporation).

A Saturday talk by Dr. Tom Clark W3IWI (**Photo A**) discussed extremely accurate time signals available via the GPS (Global Positioning System) satellites. Tom's device, called the Totally Accurate Clock, provides an interface between a small GPS receiver and a computer. The resulting timing signals are accurate to intervals of less than a microsecond.

An afternoon presentation by Ed Krome KA9LNV covered a Phase 3D-related topic. Ed presented "The View From Below: Thoughts on Phase 3D Ground Station Requirements." Due to the many ham bands covered by Phase 3D, the nature of the final orbit and the power output of the satellite's transmitters, working Phase 3D from the ground will be quite different from current satellites. Ed proposed the use of small microwave dishes with multiple concentric or offset feeds and small VHF/UHF yagis all mounted on a single boom. The use of mast-mounted downconverters and transmitconverters was proposed for modifying current ground-based systems to operate new modes of Phase 3D.

Saturday was not all Phase 3D. Past AMSAT board member Harry Yoneda JA1ANG provided an update on the operation of Fuji-OSCAR-29. AMSAT President Bill Tynan W3XO presented some thoughts on possible projects beyond Phase 3D. AMSAT Vice President of International Affairs Ray Soifer W2RS gave his observations on the "Amateur Satellite Service in 1996," while Richard Limebear G3RWL expressed his concern for the future of amateur satellites.

Prior to the banquet, Bill Tynan hosted the annual AMSAT meeting with members of the Board of Directors and AMSAT officers on stage. This is always a great opportunity for AMSAT members to ask questions of a group that is only together in one place once a year.

Following the meeting and some time out for "attitude adjustment," the yearly banquet, awards presentation and prize drawing were held. The banquet speaker was Darrel Emerson AA7FV. Darrel is in charge of the 12 meter radio telescope on Kitt Peak near Tucson. His discussion of radio astronomy and the pioneers that opened up this fascinating field was quite thought-provoking. It was also a preparation for the incredible tour scheduled for Sunday.

At the awards presentation many AMSAT supporters were honored and a special plaque was presented to the American Radio Relay League for their work to provide over $500,000 for the Phase 3D program. After the awards, prizes finished the evening. They ranged from books, T-shirts and maps to gear from SSB Electronics, an antenna system from Larsen, a mobile transceiver from Kenwood and an all-mode VHF/UHF transceiver from ICOM.

Sunday

Following the Field Operations Breakfast at 7:30 a.m., everyone took off for Kitt Peak in chartered buses. For satellite enthusiasts it's hard to imagine anything more exciting than the close-up tour of the Phase 3D facility that occurred at the 1995 AMSAT Space Symposium. Kitt Peak may not have any satellites to look at, but the technology, electronics and giant dishes of the National Radio Astronomy Observatory were incredibly impressive. The AMSAT Board of Directors meeting was postponed so that everyone could attend.

The tour included the 12 meter radio telescope (good up to 300 GHz) and the 75 meter radio telescope (good up to 47 GHz). The 75 meter dish is part of a global network of identical dishes that are used together to create the VLBA (Very Long Baseline Array). Tom Clark W3IWI provided details about the coordination of observations between locations.

A walk through of the 12 meter dish control room and a "hard-hat" climb through the feedline room at the back of the 75 meter dish provided real perspective to the show. The clear air, high altitude and incredible view in all directions are hard to describe when experienced from the support structure of a giant radio telescope.

The tour didn't end with the radio telescopes. The Symposium attendees also got a chance to view the Mayall 4 meter optical telescope, the 2.1 meter telescope and the incredible National Solar Observatory. The solar "telescope" is 500 feet long, mostly underground, and looks like a giant temple built by an ancient or alien civilization. It is used to study the complex surface motions of the sun in order to gain a better understanding of the interior.

After the all-day tour, Bill Tynan W3XO started the AMSAT Board of Directors' meeting, which lasted through mid-Monday with a few breaks for food and sleep. The agenda covered many items, including publications, SAREX, ARISS, long-range planning, new satellites and the budget. The Phase 3D program was again the main topic. AMSAT still has a significant challenge ahead to pay its part of Phase 3D and maintain other activities. Launch date slippages cost money, just to keep testing and other contract work going until launch.

Toronto, Canada, is the site for the 1997 meeting. It is sure to be a fascinating event since Phase-3D will be in orbit by then. Watch for more information on the AMSAT Web page at http://www.amsat.org.

Copies of the "Proceedings" of the symposium are available from AMSAT or the ARRL. The softcover book is 8 1/2" by 11", 232 pages. It's well worth the cover price of $12. AMSAT can be contacted at 1-301-589-6062 for details on shipping charges. 73

HAM TO HAM

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

Just a reminder to keep the "Ham To Ham" column in mind whenever you run into an interesting solution to a problem in your pursuit of amateur radio. I need lots more input to keep the column lively and interesting. Any idea, suggestion, tip or solution is fair game, as long as it has applications to the hobbies of electronics and ham radio. We've all discovered unique approaches and resolutions to our common problems, and "Ham To Ham" is the ready forum for sharing them with other *73* readers. Just jot down your ideas and send them to the address above; I'll let you know if I can use them and roughly when they'll appear. Include an informal sketch if you feel that would help explain your suggestion, and a short text (handwritten or typed), and I'll take it from there. I'll put it into the tone of wording that I've been using for the column and redraw the illustration if needed, so don't let formality hold you back. Now to this month's ideas.

"By merely typing 'dir,' on an infected disk, you can spread the virus to your hard drive!"

Viral protection

From Terry Huckleberry N5FYI: Protecting your computer from an insidious viral attack: "Most virus infections occur as a result of people exchanging diskettes. The best mainline protection against infection is therefore the pre-screening of *any and all* incoming disks. Even before reading the disk's directory!

"Most viruses also lie dormant for a period of time, before self-activating and causing any critical damage to your system. During its dormant stage, however, the virus can be reproducing, spreading itself into other areas of your system, undetected. The sinister virus programmers aren't looking for instant destruction, but rather for the widespread latent destruction made possible by waiting patiently to attack. This is one of the features that can make the more sophisticated viruses so devastating. Early discovery and elimination ends the virus's life-cycle.

"The solution? Virus-scan *everything* that you import into your computer before doing anything with that program. Scan all outside floppies before even reading their directories. A friend of mine recently downloaded a virus scanner and found that there was a virus in the zip file of the virus scanner itself! Scan each installation of every program or data file; in most cases, you can stop the viral spread beyond the initial file that contains the disease if you're consistent with this policy.

"Any virus detected should be considered dangerous!

"A further warning: Even factory-sealed program disks can't be considered absolutely virus-free, and due to the way in which files are often packaged, a program loaded directly from a factory-boxed disk can't usually be fully virus-scanned until it's installed on your system. The best policy then is to re-scan for viruses after each installation (and before actually running the program) on any newly installed outside programs. This may seem extreme to some, but so is the damage that can occur from an infected outside disk."

Moderator's note: Terry brings up some important points. It's a shame that we even have to worry about things like this, but we've all heard the horror stories of intentional viruses. As programming techniques and packaging alternatives become more sophisticated, it may be less likely that viruses will be able to spread as readily as they do today, but until that time, it's best to stick with the safest approach. There are numerous virus scanning programs available today, and Terry mentioned that he's had good results with F-Prot© and Thunderbyte© virus scanners, to name just two. Additionally, make sure that your anti-virus program is a recently updated version; as the anti-virus scanners become more adept at ferreting out the culprits, the virus programmers often counter with sneakier viruses, reminiscent of the old nuclear "Cold War" days!

From Rich Measures AG6K: Some tips for dispelling the equalizing resistor myth, and straightening out some of the confusion surrounding the use of equalizing resistors and capacitors across high voltage diodes: "In days of yore, when silicon diodes were first introduced to the consumer electronics market, the absolute 'need' for equalizing resistors and equalizing capacitors across the newly discovered critters was admitted by virtually everyone. Today, things are a lot different. Silicon rectifier manufacturing technology has come a long way, and inherent similarity from device to device is the norm, not the exception. So are equalizing resistors and equalizing capacitors across the current offering of silicon rectifiers really needed now?

"No. In fact, they can actually cause problems of their own in the series high-voltage power supply circuits found in most amateur HF linear amplifiers. Here's why: The little 1/2 watt carbon composition resistors normally used in this service were never designed to handle more than about 350 volts maximum DC across their relatively small carbon elements; most high voltage diode stacks used in modern linears are expected to carry twice that voltage, or more, safely. So, over time, internal stresses within these 350 volt resistors can eventually cause one or more to break down—usually by decreasing gradually in value—and then the domino effect takes over. In short, one or more resistors fail, putting that much more strain on the rest, and eventually causing catastrophic failure of otherwise perfectly good parts in a series circuit such as the one described.

"Instead of using equalizing resistors and capacitors these days, just make sure that the total PIV of the entire silicon rectifier stack will handle the total peak voltage to be expected, with substantial safety margin to spare, and leave it at that.

"One factor that should be recognized, however, is that all of the rectifiers in a series-connected circuit should have similar junction capacitances—using the same type number rectifiers will normally assure this. If they're not equal, then the reverse-voltage across the lower capacitance rectifiers will tend to be excessive, because smaller capacitors charge faster than bigger capacitors. It's a good idea, therefore, if rectifier types must be mixed in a series circuit, to equalize with disc capacitors. If some 6 amp rectifiers are used as replacements in a circuit using 1 amp devices—assuming that's all that the repairperson has on hand—then a .01 µF disc cap across each device may help, but only because of the wide variation between those 1 amp and 6 amp rectifier natural junction capacitances. Again, there's no need to add 'equalizing' caps and resistors in a series circuit having all the same part numbers—and it can even do harm.

"Here's one thing of interest that I once ran into, though it's not by any means a common problem. I encountered a production run of silicon rectifiers that apparently had poor spot-welds inside the rectifier casing itself. Internal heating and cooling eventually caused these welds to break, completely opening the rectifier from current flow—not a healthy condition in a series HV circuit. If one of the capacitors in the circuit is not being charged by its respective rectifier, then reverse current can be forced though it, and the results are noisy and messy. If you ever run into just one open silicon rectifier in a series HV circuit, don't take chances. For the 10 cent price of a rectifier today, replace all of them, just in case it was the product of a poor manufacturing run. The normal failure mode for these devices is a dead short, caused by too much forward or reverse current, not an open. Be forewarned. Be suspicious."

Power supply tips

From Peter Albright AA2AD: Some tips and techniques on practical linear power supply troubleshooting. "Linear (not 'switching') power supplies are sometimes the easiest of the many circuits to be found in ham transceivers to troubleshoot, and they're also often the most prone to failure due to the demands imposed upon them. Quite often, diagnosis of other circuit failures can be traced to incorrectly operating power supply circuitry, so this part of the chain should always be checked for proper operating parameters before going into the more complex circuitry.

"Most power supplies can be thought of as containing five basic blocks: 1) the input interface block (the input line cord, protection circuit, power transformer, etc.); 2) the rectifier block (where AC is converted into pulsating DC); 3) the filter block (where the pulsating DC is converted into smooth DC); 4) the regulator block (where output voltage stability is determined); and 5.) the output interface block (where current limiting resistors and/or wires and PC board traces carry the supply voltage to other stages of the transceiver). By thinking of the power supply in terms of individual blocks, it's often easier to isolate problems in the power supply using the logical steps of elimination.

"The first analysis of any suspected power supply problem can begin with the unit's cover in place. Is the line cord in good condition, is the fuse intact (if accessible from the outside), what (if anything) unusual was noticed at the moment of failure, was anything spilled on the unit or did a voltage surge or lightning strike occur? Was there any smoke or perhaps unusual noise associated with the failure? All of these 'external' clues can help lead us to the eventual solution to the problem. Always look first for the obvious, it can save countless hours of needless troubleshooting time (an intermittent AC line cord or fuse holder, for instance).

"Once the cover is actually removed, leave the equipment unplugged and begin your visual inspection. Do any parts appear to be overheated? The transformer should be carefully inspected for signs of excessive heat (and odor associated with hot varnish), resistors should not appear darkened or discolored, electrolytic capacitors should not be leaking or bulging and all wiring or printed-circuit board traces should be free of signs of excessive heat or thermal stress. Do the solder connections look clean and bright and are component leads clipped off so that they won't short to adjacent solder pads? Checking the power supply circuitry visually can save a great deal of time and effort if done systematically and with care. Anything at all that 'appears' suspect, should be removed and checked (or substituted) before going on.

"Now we're ready for the power-on test, but be very careful—most power supply circuits can have lethal voltages present when operating, at least in the area of the primary fuse and the AC line circuitry. Always know where these points are before putting your hand inside of the chassis and proceeding with any voltage tests.

"Having a schematic diagram can be a big help at this point. Check the diagram and locate the output regulator or regulators, then measure their input and output voltages with respect to ground. If you don't find the expected voltages (which are generally indicated on the diagram), then the problem could be in either direction, i.e. either the correct voltage isn't being applied to the regulator's input, or the regulator is bad or the output voltage is being dragged down by a higher-than-usual current demand somewhere in the circuitry that's being fed by that regulator. If you can open a link to that subsequent circuitry (by removing one end of a resistor, a steering diode or simply removing a wire), then you can eliminate the circuitry being supplied power as the source of the problem.

"If you don't have a schematic diagram or other technical information, all isn't lost; often you can assume that the normal voltage reading obtained with a voltmeter across each of the large electrolytic filter capacitors will be about 80% of the voltage marked on the capacitors. It's not exact, but often enough to determine proper operation at least. Many times, voltage regulator ICs will have their regulated output voltage coded into the part number, such as a 7805 is a 5 volt regulator and a 7812 is a 12 volt device. Again, by working back through the various blocks, you can often tell if a reading 'seems' normal or if it's 'out of the ballpark' altogether. Experience helps, but experience is only gained through actual troubleshooting practice. Chances are, you'll do better than you think you're able to do, just by using these logical steps and thinking of the circuits in terms of the five basic blocks mentioned earlier. Why not give it a try?"

Moderator's note: Pete does a good job of outlining some time-honored procedures for power supply troubleshooting. Knowing the normal failure modes of components is also helpful when attacking power supply problems; here are a few:

Fuses always open (badly blackened fuses usually mean a high-current short). Power diodes normally short (smaller signal diodes, LEDs and small zeners usually open). Resistors normally open or change value with overheating. Transformers can open or overlapping turns can short internally (some transformers have internal thermal protectors that can open). Dry capacitors (such as disk capacitors) normally short or become very low-value resistors. Electrolytic capacitors can leak, dry out and lose their capacity to store energy. They can also short, often with dramatic results. Voltage regulator ICs can open, short or change their output parameters (they can also oscillate at times).

Note that these are the normally "expected" failure modes of components in power supply service, others are also possible. I've seen power transformers go up in smoke, high voltage electrolytics explode, regulator ICs blow apart into tiny pieces, resistors sputter and smolder, plastic insulation on wires completely melt away and fuses weld themselves inside of their holders. Power supplies or their feedlines are generally where these sorts of things happen, so any suspect power supply component should be considered for replacement as a precaution.

Cable IDs

From Dave Hyman KBØONF: "Time to start saving those little square plastic closures often found on plastic bread bags; they make nice cable identification tags. A drop of lacquer thinner will remove any printed matter on the tags, and a sharp black permanent marker will allow you to write your own information in its place. They fit nicely on most sizes of cabling found around the average ham shack, but the hole can also be enlarged a bit with a hobby knife if needed. If the tag refuses to stay on a particular cable, try putting a small piece of good quality transparent tape across its split edge."

Moderator's note: Nice idea, Dave Does anyone have any other favorite cable-marker schemes? Here's something to complement any cable marking idea: Instead of trying to put all of the information needed on the tag itself, use a "cable schedule." It's simply a form (make up one and photocopy a bunch of them) that shows a cable's number (such as #100), the type of cable (RG-8X coax), the source (FT-1000MP Antenna Jack), its destination (Linear Amp Input Jack) and its purpose (RF feed from transceiver to linear). A sheet of standard (8-1/2 x 11") paper will easily hold the information needed on 20 or so cables when oriented in the 11" (landscape) direction. A cable schedule allows you to put just a cable number on each end of a cable, rather than trying to describe what the cable's function is on a rather small tag...that's all done on the schedule form sheet instead. The cable schedule form gives more information than would ever be possible otherwise, and permits you to change the function of a cable when redesigning your station—only the entry in the cable schedule form need be changed. We used cable schedules extensively in broadcast installations, considering the cables more or less permanent, and only their functions as changing. Do it in pencil. It's logical and flexible once you've become used to it, but you do have to keep it up to date if it's to be of value.

Cleaning up after a hamfest

From Mark Marholin KE6JJR: "You can often make those not-so-attractive 'hamfest specials' come back to appearing close to new, by simply mixing some hydrogen peroxide and water as a cleaning agent. Hydrogen peroxide is inexpensive, and can be obtained at any drug store, but it does a nice job of cleaning grit, grime and tobacco smoke stains from a piece of equipment. It also kills bacteria and breaks up organic matter—that might have been an unexpected bonus—with its bubbling or cavitation action. The exact proportions can be arrived at experimentally, but a 50-50 blend is a good place to start, since the typical consumer-available hydrogen peroxide is usually only about 3% strength. Give it a try and see how it works for you. By the way, it's also used as a bleaching agent, so avoid getting any on your clothing."

"Mark's tip is another reason why hydrogen peroxide may deserve a reserved spot on your bench."

Moderator's note: I've kept a bottle of hydrogen peroxide on my workbench for years for applying to small cuts and scrapes on my hands, because of its anti-bacterial properties; an MD friend told me about it long ago. Mark's tip is another reason why hydrogen peroxide may deserve a reserved spot on your bench. I've also found Dow™ foaming bathroom cleaner (available at supermarkets) good for cleaning particularly grimy equipment panels and cases. It too has a cavitation action that breaks away stubborn collected material, but test it first on an out-of-the-way spot to make sure that it's compatible with the paint and silk-screening used on your rig—you don't want to "clean away" important information!

Murphy's Corollary: Explaining something so clearly, and in such detail, that no one could possibly misunderstand it, will inevitably guarantee that someone will.

That wraps up this month's column; does anyone have any ideas on "different" uses for common items such as K9PKM gave us? Send them, or any other ham-related tips, ideas, suggestions or shortcuts to me at the address in the masthead, and I'll share them with the rest of *73's* readers. That's our purpose, sharing practical ideas Ham To Ham.

Many thanks to this month's contributors, including:

Interesting Web Sites

If you have Internet access, and are interested in looking up various callsign information, you may find the following web sites useful:

http://www.webbuild.com/~ki4hn/vanity.htm

This site contains the latest information on the issue of "vanity" callsigns. There are files which include listing of all vanity callsigns issued on each day, since about the July time frame. There are also files which contain a collection of all the callsigns issued by call area. The files are updated daily. If you are interested in following the vanity callsign program, this is a good place to look for information.

http://www.ualr.edu/~hamradio/callsign.html

This is a page at the University of Arkansas. It has an up-to-date copy of the FCC database. The information at this site is usually only a day older than the information at Gettysburg.

Essentially, this site can serve as an equivalent of the *US Callbook*. Additionally, it has some search capabilities. For example, if you want to look for all the hams with the name of "Higginbotham," the search engine will show there are 48 in the FCC database. Or, if you want to look at all the hams in North Attleboro, the search engine will show there are 74. It shows the number of hams in Attleboro to be 87, including one with a British callsign and two with Japanese callsigns.

Take a peek at either of these web sites if you happen to be "surfing the net":

www.lantz.com/cbs

This URL is a pointer to a site that tracks recent changes. It has a pointer to a US file, and it has pointers to files for each state. It doesn't, however, seem to record recent vanity callsign changes.

www.arrl.org/fcc/fccld.html

This URL is a pointer to a database of the recent FCC database changes. It is said to cover about a six-week period. You can scan this using any call that might have changed in the six-week period. You can query using either the "old" call or the "new" call. This seems to be about the best place to look for "very recent changes."

By Dick WS1H, in *"The Chirp 'n' Click,"* December 1996, the official newsletter of the Sturdy Memorial Hospital ARC.

Crunch, Crunch!

If you've spent much time around radio gear, you know it can have its share of problems, just like all electronic things. Some of the issues are similar or identical to what you find in camcorders, stereos and the like. Some, though, are peculiar to RF, and are common enough that we have names for them. One of the most often heard complaints is that a radio has the "crunchies." What the heck is that?

A "crunchy" radio is one that transmits a characteristic sound of teeth crunching. OK, it's really just a crackling noise, but it does sound like the transmitting operator is munching on popcorn while carrying on a QSO. Of course, perhaps he or she is doing exactly that! Such an obvious explanation aside, it's safe to assume the radio itself is the source of the crunching noise, and some remedy must be applied. So: What causes crunching noises in a transmitter?

Pick one

Unfortunately, there's no single cause. While it might seem intuitive that crunching sounds are generated by bad connections (and many are), the kinds and locations of those connections can be surprisingly difficult to pin down. Also, some crunchies are caused by effects not related to bad connections at all! So, let's take a look at the crunchies and how you can get rid of them.

Is it me?

Before you go trying to solve your rig's crunching problems, be sure it really is your radio that's doing the crunching! Repeaters, themselves, are quite prone to the crunchies, and many operators think their radios are the problem when the real trouble is up on a hill, miles away. Often, the listener reporting the sound is no help; it's amazing how many people forget they're operating through repeaters and attribute everything they hear to the other op's rig.

Easy crunch

Some cases of the crunchies are easily solved. If your microphone cable has a broken wire inside, it can still work because the two ends are touching each other. As you move it around, though, it'll cause massive crunchies. I've heard plenty of mobile rigs doing that, and have had a few myself. Usually, the cable damage occurs right near the plug, although sometimes it's at the mike itself. Often, you can just cut the plug off and reattach it after snipping off an inch or so of cable. Before you do, though, wiggle the cable while transmitting and listening on another rig, to be sure you've found the bad spot.

Another common cause of crunchies is the PTT switch. Older rigs used relays (themselves a serious crunchiness offender) to switch between transmit and receive. The relay didn't care about the exact resistance of the PTT switch, as long as it was low enough to provide sufficient current for pulling in the relay. With today's solid-state switching, it's another story. In most of today's rigs, the PTT line is an input to the microprocessor. Like the relay, the micro doesn't really care whether the switch has some resistance. However, that line often also does some other things, and, when the switch's resistance goes up, it can make the radio go haywire. I've seen flaky PTT switches cause everything from bad crunchies to making the radio try to transmit and receive at the same time! It pays to carefully squeeze the PTT while listening to another rig.

The other end

An often-overlooked, but common, cause of crunchies is bad antenna connections. I remember one case in which the mobile rig's SO-239 connector had accumulated greenish gunk inside, presumably because the radio was on the floor of the car and had seen plenty of rain, snow and moisture. The result was poor contact with the antenna plug, and a bad case of the ol' crunchies. That kind of antenna problem can wreck the final amp module, too, because the SWR goes up and down quickly and constantly. Luckily, no damage was done.

Naturally, bad connections to the power supply can cause crunchies. Although the problem can be at a terminal or even a fuse, it doesn't seem to happen much in mobiles and bases. HT battery tracks, on the other hand, do it all the time. Often, a good cleaning with a pencil eraser will do wonders—and that brings us to the ultimate crunch machine:

"Always check those BNCs; it makes sense to expect trouble there."

The ubiquitous HT

Although lots of different kinds of rigs can crunch, the ones I hear most often, and the ones I've most commonly had to fix, are handhelds. Heck, I've seen brand-new HTs that were crunchy right out of the box. Why are HTs so prone to this problem? There are several reasons. First, the RF output is usually via rubber duck antenna, which puts a great deal of RF right back into the walkie. That can lead to crunchies for reasons I'll shortly explain. Second, HTs are very small constructs, with sensitive stages quite close to each other, shielded only by small amounts of thin metal. Finally, handhelds take a lot of physical abuse, due to their being carried around all the time.

Shield me

When there's lots of RF pounding on the shields of sensitive circuits, as there often is in a rubber-duck HT, those shields had better be nice and tight! Even a cold solder joint can exhibit enough rectifying ability to cause RF feedback. Heck, even the unsoldered edges of small shield cans are capable of spreading the RF around unevenly enough that there's some potential between various parts of the shield. That makes the shield into a radiator, and it radiates RF right into the circuits it's supposed to shield. Now, if the exact properties of that shield vary as you squeeze or move the rig, what do you get? Yup, the crunchies!

The average modern walkie is constructed in two halves, usually with a ribbon connector between them. That's in sharp contrast to the old style of construction, which had one big board in the middle of the frame, and perhaps a small microprocessor board behind the keypad. The old way was better in one respect: It rarely led to the crunchies, because the grounds were all tied to the same frame. The newer, split style means that, right off, there are two grounds, one on each side. Remember, at VHF and UHF, it only takes a fraction of an inch for a ground plane to become an inductor, and that spells trouble with a capital "C." Most HTs have a metal tongue that extends from one side to the other and is intended to connect the two grounds. Does it work? Well, kind of. When the rig is new and clean, it works pretty well, but as the handheld ages and a little grime gets in there, and the tongue's spring tension relaxes, the integrity of that all-important connection gets questionable. You squeeze the rig, causing the tongue to rub slightly against its contact on the opposite side of the radio, and it makes that characteristic sound. The rig goes "crunch."

Mostly on TX

Why does this problem affect transmitting so much more than receiving? On receive, there's no

big source of RF against which the shields have to protect. Sure, the various internal oscillators make some noise, but not at the level of watts of power! Shielding and grounding problems that aren't even *noticeable* on receive can be troublesome on transmit. I remember one stubborn case of the crunchies in a brand-new HT that turned out to be a cold solder joint on one of the four corners of the shield over the VFO circuit. The rig worked fine on receive but was intolerably crunchy on transmit. As it turns out, VFO and PLL circuitry is particularly sensitive to shielding problems. Heck, this radio had three of the shield's four corners soldered just fine, and it still didn't work right! If you have a crunchy rig and the obvious solutions aren't working, check those shields on the circuit board. You can usually spot the ones over sensitive circuitry because there'll be a hole for adjusting a coil or trim cap.

I had another crunchy handheld I was sure had this problem. I soldered *everything* I could find, and it still crunched. I even soldered parts of the frame together, because they were held only by tiny rivets, and I thought perhaps that was the problem. No dice. No matter where I pressed, the rig crunched. It finally turned out to be a dirty BNC antenna connector! I cleaned the hole on top with a tiny rolled-up piece of paper soaked in contact cleaner, and the problem went away. From now on, I'll always check those BNCs. After all, the contact area is pretty small, and it's exposed to lots of environmental stuff like dirt, smoke and moisture, so it makes sense to expect trouble there.

By the way, HF rigs can be crunchy, too, often for the same reasons as VHF/UHF radios. Some cases of HF crunching, though, are caused by simple RF feedback into the microphone amplifier circuit, so always check for that by transmitting into a dummy load before assuming the radio has a real problem.

Well, I think we've crunched enough for one month. Next time, we'll look into something else. Until then, 73 de KB1UM.

NEVER SAY DIE

and not one like 99.99% of the magazines you read, but like mine. What would you write about? Try sitting down at your word processor and let's see what you can come up with.

Have you had an exciting adventure in amateur radio? Have you read a book that you think everyone really should know about? If you haven't had any exciting amateur radio adventures, why the hell not? What's wrong with you? The doors to adventure are right there in front of you at every turn. Are you blind? And if you haven't read a truly fantastic book recently, why not?

Have you done anything, learned anything, built anything, which might be of interest to the *73* readers? If so, start writing. If not, get a life. It doesn't have to cost a lot to get on packet or our ham satellites. Heck, a DXpedition to St. Pierre or Anguilla doesn't cost much, and will give you things to write (and even talk) about for years.

Or maybe you're a CW fanatic and can tell us how you went about learning to copy the code at 50 wpm? Or faster? If you wanted to, I'll bet you could learn to copy 50 wpm in two or three weeks and have the time of your life. But then you might want to get Congress to pass a law making everyone else learn to copy 50 wpm. Or become an ARRL Director. Or both.

You're an editor. You have a deadline coming up in a couple of days. What are you going to write about? Now get busy. If you can get me excited enough, I'll publish it. Oh yes, don't forget to send both hard copy and a disk. And please don't forget to use your spell checker.

I'll tell you what. If I find I'm getting more good stuff than I can fit into *73*, I'll reprint your editorials and send copies to the editors of the several dozen ham club newsletters I'm getting. Many of 'em are in pathetic need of interesting material.

Once you get the hang of writing you'll be surprised at how easily the ideas come. I've never had a time when I sat down to my typewriter or word processor and was stumped for something to write about. No dry spells. Worse, I've gotten way ahead. A few months ago I published a

Radio Direction Finding

Build a multiple polarization quad

Cubical quads are the most popular antennas for VHF and UHF radio direction finding (RDF) in many places around the country, including Southern California. One reason why you see so many quads on vehicles at our hidden transmitter hunts (T-hunts) is that quads can easily match the polarization of the hidden signal. This can make the difference between success and failure in some cases.

Let's say that the signal you're tracking has horizontal polarization, but you are using a vertically-polarized RDF system[1]. This cross-polarized condition means that the direct incoming signal is between 14 and 25 dB weaker in your receiver, reducing your effective RDF range. Worse yet, any signals from the hider that propagate to you by reflection from nearby buildings, intermediate hills, and distant mountains undergo a polarization shift. That makes them appear stronger, relative to the direct signal, than they would if your antenna had horizontal polarization. As a result, you might end up chasing reflected signals throughout the entire transmitter hunt, never getting accurate bearings on the direct signal.

With a simple slip joint at the boom-to-mast junction, a 2 meter quad is easily changed from horizontal to vertical polarization or to any other linear polarization angle. By adjusting your quad's polarization to maximize signal strength at the start of each T-hunt, you can avoid the problems of hunting cross-polarized signals.

The slip joint method has a few drawbacks. Sometimes it's not easy to tell for sure what polarization the hider is using, so you must check again occasionally as you progress toward the T. That's not fun if you have to stop and get out in the rain. Sometimes there are several transmitters to be found with different apparent polarizations, requiring frequent changes. Wouldn't it be better to be able to make the selection quickly from inside your vehicle?

Crossed yagis have been successfully used by T-hunters for polarization agility. Back in April 1989, "Homing In" described the setup of Vince Stagnaro WA6DLQ, who put the elements of two KLM yagis on one boom with separate feedlines and a switchbox to select six polarization modes. Many T-hunters, including your columnist, prefer quads to yagis because they are more compact. A typical mobile-mounted quad provides a better RDF pattern than a yagi of the same size. Hence, I have considered designing and building a multiple-polarization RDF quad for a long time. A recent inquiry by KD6IFZ on the Internet T-hunting mailing list motivated me to move the project onto the front burner.

> **"By adjusting your quad's polarization to maximize signal strength at the start of each T-hunt, you can avoid the problems of hunting cross-polarized signals."**

One quad, two feedlines

While separate driven elements for horizontal and vertical polarization on one quad could probably be made to work, a more elegant solution would take advantage of the cubical quad's inherent symmetry, which makes all elements able to support both polarization modes simultaneously.

Let's go back to basics for a moment. AC currents at VHF frequencies in antennas behave differently from AC currents at 60 Hz in your house wiring. The quantity of electrons passing per second along the power cord of your toaster is the same at the plug end, the toaster end, and everywhere in between. But if you could measure the RF current at several points along the driven element (DE) of a quad antenna, you would find that it differs. This property makes the DE radiate transmitted signals and pick up received signals.

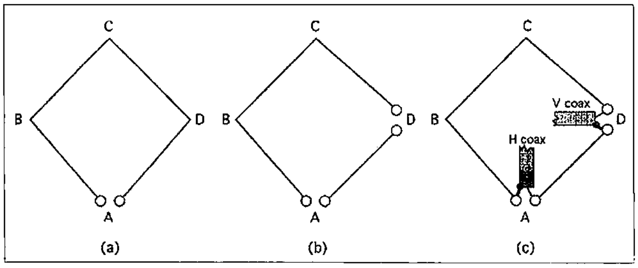

Fig. 1. At (a), the driven element of a horizontally-polarized quad. The feedline connects to point A. Breaking the loop at point D as in (b) does not affect horizontally-polarized operation. Attaching feedlines at A and D as in (c) allows extraction of both horizontally- and vertically-polarized signals, if the outsides of the coaxes are decoupled.

Fig. 1(a) shows a typical quad driven element loop. Circumference is one wavelength, about 80 inches at 2 meters. The feedline is connected to point A, which gives a horizontally-polarized transmitted signal. Received signals of horizontal polarization induce currents in the loop that go down the feedline to the receiver. Vertically-polarized signals induce currents within the loop also, but magnitude and phases are such that they cancel out at point A.

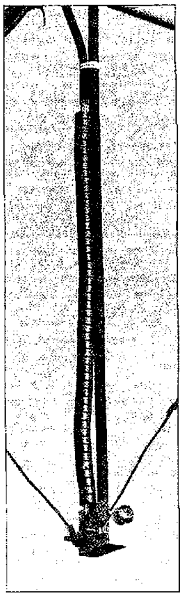

***Photo A.** One of the 50-bead baluns without the heat-shrink tubing.*

RF current from the transmitter is highest at point A. There is another transmitting current maximum at point C. At points B and D, current is at a minimum. Theoretically in a perfect quad, loop current would be zero at these points. In a practical beam, it is less than 1 percent of the maximum.

If there is indeed no current at point D, why can't we just break the loop there, as in **Fig. 1(b)**? You can! If you have antenna analysis software such as ELNEC[2], try this as an "exercise for the reader." Insert a very high value resistive load at point D in the DE of your favorite diamond quad model for any band. If the quad is symmetrical, then the resonan frequency, pattern and feed point impedance will show very little change.

With the added break, we have the driven element of **Fig. 1(b)**. Feeding it at point A gives horizontal polarization, while feeding it at D gives vertical polarization. Both modes can be handled by the quad simultaneously. So why not just hook a feedline to each point and switch from one to another at the receiver, as in **Fig. 1(c)**?

Whoa! Breaking the loop and adding a 50-ohm load at a current minimum will not affect it, but adding an unbalanced feedline certainly will. The braid of the coax becomes part of the antenna. As another ELNEC exercise, hang a long wire (representing the

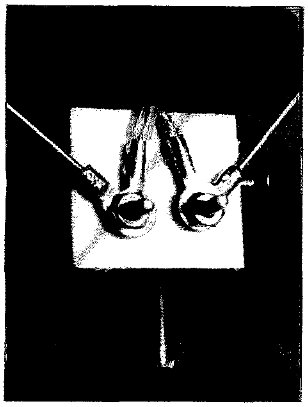

Photo B. Close-up of a feed point block. The first bead fits over the point where coax shield and center conductor are separated.

coax shield) at a current null point in your favorite quad DE and watch the pattern change for the worse.

Fortunately, current flow on the outside of the coax can be choked off to restore the current minimum. A balanced-to-unbalanced transformer (balun) will do it. RF current will be confined to the coax inner conductor and the inside of the shield, and will remain near zero for cross-polarized signals. For the unused polarization mode, it is almost as if the coax isn't there at all!

VK5RN has documented a circularly-polarized quad for OSCAR satellite work that has two feedlines with sleeve baluns[3]. These devices, sometimes called bazookas, are made from thin-wall metal tubing of carefully selected diameters. I did not want to use a pair of bazookas on my T-hunt mobile quad because they are heavy and would add lots of asymmetrical windload at freeway speeds. Instead, I tried a choke of ferrite beads. Measurements by W2DU[4] show that 25 beads of #43 ferrite material over a coax line provide 850 ohms impedance to currents on the outside of the shield at 2 meters.

Does it work?

I built a modified Cubex Yellowjacket[5] four-element 2 meter quad by installing two feedline termination blocks instead of one. Part number FB-43-2401 beads[6] have an inner diameter of 3/16", so they fit nicely over the RG-58/U feedlines once the outer jacket is removed. The two feedlines go down the 3/4" Schedule 40 PVC pipe mast to a two-position coax switch in the van, then to the receiver. Coaxes are exactly the same lengths to make it easier to achieve circular polarization, as will be shown later.

At a local hilltop, I compared the new dual-polarization quad to an unmodified Cubex Yellowjacket using a calibrated attenuator plus local and distant repeater signals. The results delighted me. The directional pattern of the dual-quad was just as good as that of the reference quad. Cross-polarized signals were attenuated 14 dB by the dual-quad, which represents about 3/4 scale on my receiver's S-meter.

Forward gain of the dual-quad was about a half dB less than the reference, a negligible difference. Making the comparison was difficult because when testing the stock quad, the S-meter would vary plus or minus 20% as the feedline was moved around inside the van, due to feedline signal pickup. On the other hand, output of the dual-quad was rock solid with feedline movement, thanks to decoupling by the ferrite baluns.

About this time, a Saturday night mobile T-hunt was getting underway. I decided to give the quad a real workout. KD6LOR and KK6ME had put out three hidden T's, transmitting intermittently on 146.565 MHz. Only one was copyable when I left the hilltop. By switching between feedlines, it was easy to tell that this signal had horizontal polarization. After I had gone a few miles, I began to detect weak signals after each transmission from the strong T. I toggled the coax switch a few times and determined that the weak signals were stronger in the vertical mode.

I found the strong signal first. It was in KD6LOR's truck in a parking lot overlooking Mission Viejo. Sure enough, its transmitting antenna was a horizontally-polarized quad. I then took on the other two T's, which clearly had vertical polarization. There was now a bit of overlap in the transmissions and it was nice to be able to switch polarization to minimize the signal from the horizontal T while hunting the others.

Before long, I had found both of the weaker T's. Each had a quarter-wavelength vertical whip antenna mounted on a surplus ammunition can. One was chained to the base of a high voltage power line transmission tower, while the other was in a park on a steep hillside overlooking Lake Forest. This hunt was enough to convince me that a polarization-agile quad would be my new "weapon of choice" for many future hunts.

Although gain and pattern of the test quad proved to be excellent, SWR was over 2.5:1. Upon further testing, I found that the DE was resonant at about 141.5 MHz. Apparently the pigtails between the ends of the bead baluns and the feedline blocks add to the DE's resonant length. I shortened the DE wires, which improved SWR but caused the pattern's back lobe to worsen. After some experimentation, I found that moving the reflector four inches closer to the DE made the SWR even better and minimized the back lobe.

SWR is now 1.6:1 for both polarizations. This is fine for receiving, because the feedline is decoupled well. Your receiver probably does not have exactly 50 ohms input impedance anyway. I also tried 50 beads per balun instead of 25 (**Photo A**). This increased cross-polarized signal rejection from 14 to 17 dB.

You can make one

Your favorite 2 meter corner-fed no-gamma diamond quad design should be suitable for use with this dual-polarization feed technique. Baluns of 25 beads each are adequate for RDF and inexpensive.[7] You will need to strip the jacket from RG-58/U coax for the beads to fit. Do not strip or comb the shield braid under the beads. If your coax diameter is so small that the beads will go over the jacket, it is not standard RG-58/U and not recommended for VHF.

Cover each balun with heat-shrink tubing and add a dollop of hot glue or other sealant at the ends before shrinking to keep water out. Keep the shield and center conductor leads from balun to feed block short. Remember that they add to the DE resonant length. These pigtails are just 3/4" each on my quad (**Photo B**), compared to 1-1/2" in the Cubex instructions.

As a check of your dual-feed quad's construction, try

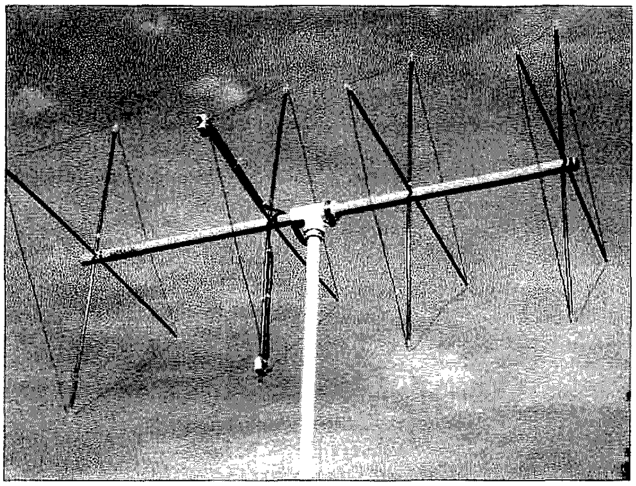

Photo C. The dual-quad is mounted and ready for a hunt. Note that the feedline passes over the top of the boom, but does not wrap around as it does in stock Yellowjacket quads.

transmitting on 2 meters into one feedline while terminating the other with a wattmeter and a good VHF dummy load. Very little RF should leak from coax to coax. In my case, transmitting 22 watts into the horizontal coax gave only 6 milliwatts out of the vertical coax, and vice versa (35 dB isolation).

Wire lengths of the DE on my modified Yellowjacket are 18-3/4" for the wire between the two feed blocks (measured screw-to-screw), and 59-3/8" for the wire that forms the other three sides of the loop. Lengths of the other Cubex element wires are unchanged. Cubex instructions call for six turns of feedline around the Yellowjacket boom, but these added turns are unnecessary and undesirable when the ferrite baluns are in place (**Photo C**). Cubex suggests using RG8X low-loss feedline, but the difference in loss for short mobile T-hunting feedlines is negligible.

Hiders occasionally transmit unusual polarizations. For instance, an ammunition-can T propped up in a tree may put out a signal polarized at a 45-degree angle between horizontal and vertical. There have even been some circularly polarized T's to find on our Saturday night hunts.

By combining signals from the horizontal and vertical feedlines of the dual-quad with proper phase relationship, you can achieve 45-degree and circular polarizations. "Homing In" for April 1989 has plans for WA6DLQ's six-position polarization switchbox. Though intended for use with his dual-feed yagi, it will also work with the dual-quad. A similar switchbox is in the Radio Society of Great Britain's *VHF/UHF Manual.* Feedlines from switchbox to each feed point must be exactly equal lengths when using the switchbox.

If T-hunting in your area requires you to make frequent polarization decisions, consider adding a dual-polarization quad to your bag of tricks. Ed Buchanan of Cubex has agreed to sell a dual-feed version of the Yellowjacket quad to "Homing In" readers. It includes two feed point termination blocks and associated hardware. Contact Cubex directly and ask for the T-hunt Special. Please understand that I have no business association with Cubex, so do not send inquiries about this offer to me.

Whether you make your own dual-polarization RDF quad or try the modified Cubex Yellowjacket, let me know how it works for you. Send E-mail to Homingin@aol.com, or write to me at the address at the beginning of this article. Don't forget to check out the Homing In Web site: http://members.aol.com/homingin/ is the URL.

Microwave Stripline Retuning Procedures

This month I would have liked to cover the synthesizer that I used for the 1296 MHz transverter presented last month. However, I haven't completed the conversion documentation in sufficient detail. I *have* made the unit function as described. Still, notes and other details must be reconfirmed for accuracy—I will get the details to you as soon as possible.

Instead, this month I will continue trying to provide ideas on how to convert surplus microwave material for use on the amateur bands. This has been partially covered, but here are the full-blown details covering tuning procedures, and specifically the methods that Kerry N6IZW and I use in converting microstripline circuitry. These procedures were developed by Kerry and are presented in a general format, suitable for all microwave/UHF amateur bands of interest. Here are Kerry N6IZW's modification details for retuning surplus microwave microstrip circuits for the amateur bands:

In recent years, considerable quantities of surplus microwave equipment have become available to the amateur community. The reasons for adapting surplus equipment rather than building from scratch often include cost, time and performance. The cost for a typical piece of microwave surplus purchased by an astute amateur will be far less than the cost of a few new components. Often many hours that would otherwise spent in locating components, fabricating boards, and building enclosures are saved.

The performance obtainable is usually quite good due to the commercial processes used to fabricate the units in quantity. Most surplus microwave equipment is tuned for commercial or military frequencies, making it unusable on amateur frequencies without modification. This is what causes the same piece of equipment to be so much junk for one person, but a treasure for someone equipped for retuning.

High technology: good news and bad news

Microwave circuit fabrication techniques have progressed from waveguide to microstrip printed circuit boards to ceramic substrate hybrids to large-scale monolithic integrated circuits. Waveguide-type equipment still finds favor among those beginning on the amateur bands at 5.7 GHz and above, but microstrip circuits are prevalent among those building medium- to high-performance amateur equipment through 24 GHz. The good news is that the microstrip surplus is typically available because the industry is moving into higher and higher integration technologies such as the hybrid or MMIC.

The bad news is that the newer technology equipment often contains integrated components which are internally matched or tuned for a specific frequency and are not practical for most amateurs to modify. An example of a nonmodifiable piece of surplus is the typical VSAT terminal now becoming available. These units contain >1 watt transmitters at 14 GHz and low-noise receivers around 12 GHz, but are so highly integrated that very few of the microwave components are usable for amateur purposes.

The conversion of microwave surplus equipment may eventually dwindle as the modifiable technologies disappear, but this should not be a problem for some years to come. Another good side of the newer technologies is that they provide high performance with low cost and ease of application for those assembling their own microwave circuit boards

using new components. Below are some examples of successfully modified surplus equipment.

C-band TVRO LNAs

These low-noise amplifiers are available in the $5 range at local flea markets. In their original condition, they provide about 50 dB gain with a 1 dB noise figure over the 3.7 to 4.2 GHz range. They require about +15 to +24 to operate with power being supplied to the output connector. When the internal filters are removed the amplifier is usable over the .8 to 4.2 GHz range, with the noise figure increasing to about 3 dB at the low end. I have used one of these units as the 2.4 GHz LNA for an OSCAR-13 receiver.

Ku-band power amplifiers

Several types of 14-14.5 GHz power amplifiers with 25 dB or more gain and .5 to 2 watts output are available for about $35. These units are readily retunable for use on the 10 GHz amateur band, with somewhat increased output over that available at 14 GHz.

Ku-band LNA

Several types of Ku-band TVRO and VSAT LNAs are available in the $20 range. These can typically be retuned for use on the 10 GHz amateur band, providing 20 dB gain and a 1 to 3 dB noise figure.

Tools and test equipment: signal sources

Almost any available source that can be set to the frequency range of interest can be used. Usable sources include commercial signal generators as well as Gunn, transistor, FET, and YIG oscillators. The frequency stability of most sources is more than adequate for tuning microstrip circuits. Short-term amplitude stability is needed; often a single matching element adjustment may change the output by less than 1 dB. The signal level needs to be large enough at the beginning to have measurable output appear, but should be reduced to keep any stages from possibly saturating. For small signal devices the input should not exceed about +5 dBm to prevent device damage.

"An astute amateur can buy a piece of microwave surplus for much less than the cost of a few new key components."

Attenuators

Attenuators (3 dB minimum) should be applied directly to the input and output of the circuit to be tuned, for two reasons: To reduce any possible test setup mismatch that might otherwise be compensated for in the tuning process, and to protect the power measuring equipment and the equipment being tuned. This is a particularly important point when working with power amplifiers which may accidentally oscillate during the tuning procedure.

Power monitors

Almost any type of power monitor can be used as long as it has sufficient resolution and stability to identify changes of .5 dB or less. I started with a spectrum analyzer but found a power meter to be much more satisfactory for detailing small changes.

Power supplies

Power supplies should be well regulated and have current limiting which is adjustable to just above the nominal operating current. The bipolar devices typically use a single power supply while the GaAs devices typically require a negative gate bias. The gate bias should normally be applied prior to applying the drain voltage to prevent possible device damage caused by the transistor attempting to turn on hard.

My experience has been that the properly adjusted current-limited supply will prevent device damage should the gate bias be accidentally removed during the tuning process. Always remove power when making connections and soldering tuning stubs. Make sure the amplifier output is terminated before applying power. The power supply ground output should be connected to earth ground.

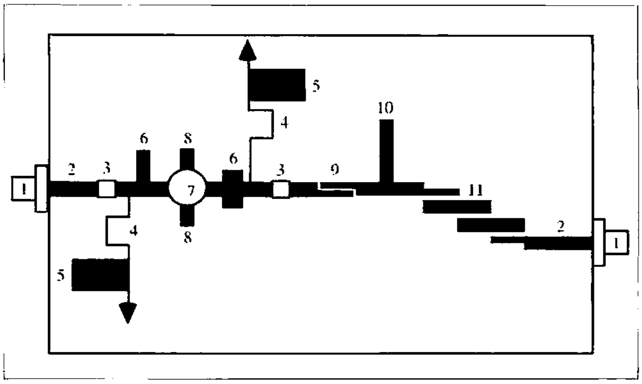

Fig. 1. Typical microstrip circuit components, showing layout of microwave amplifier filters and associated stripline components:
1. RF input/output connectors
2. Main 50Ω microstrip transmission line
3. DC blocking/interstage coupling capacitors
4. High impedance bias lines >100Ω, usually 1/4 wavelength (as long as these are narrow lines, no modification needed
5. 1/4 wave pads to provide RF ground to bias lines (open one end), normally no modification needed
6. Matching stubs may be symmetrical or asymmetrical (may need to be removed for best results)
7. Bipolar or FET device: FET gate values typically -.5 to -1.5V; FET drain values typically +2 to +9V
8. Emitter or source ground pads (direct connection to ground plane is critical)
9. Interstage filter/DC block; typically, cut with craft knife and insert capacitor (difficult to retune)
10. 1/4 wave bandpass filter (one end grounded), typically disconnected at main transmission line; possibly retunable if length/ground point can be modified
11. Bandpass filter, modifiable with some success by symmetrically extending all elements of filter.

Soldering on

A soldering iron with a very small grounded tip is essential. The grounded tip is absolutely necessary to prevent 60 Hz power line or static potential from damaging GaAsFET devices. Small signal GaAsFETs are often damaged if the gate voltage exceeds 3 to 5 volts. The drain voltage limit is typically 5 to 8 volts. The limit for power devices is usually a few volts higher.

Microstrip tuning techniques

Here is the basic approach I have used to retune many surplus amplifiers:

Everything must be grounded to power (earth) ground including the soldering iron tip. The typical FETs in microwave amplifiers will self-destruct with more than 5-10 volts on the gate.

Apply only as much input RF power as required to get usable output measurement. This reduces the chance of damage to higher power devices prior to getting the output matched. Also, it prevents saturation of a stage which then appears not to respond to tuning. Applying more than about +10 dBm directly to small FETs may cause damage.

Use current-limited power supplies set to limit slightly above the normal expected operating current. This will in most cases prevent blowing up the FETs if the negative gate bias is missing or something is accidentally shorted with the tuning wand. With this approach, sequenced turn on of

the power supplies is not usually important.

Place attenuators directly at the input and output of the amplifier. This removes the effect of poor cable, source and power detector matching. Always remove power when making connections and soldering tuning stubs. Make sure the amplifier output is terminated before applying power.

"Several types of 14-14.5 GHz power amplifiers are readily retunable for use on the 10 GHz amateur band."

Tuning procedure

Prepare the tuning wand and tuning stub material. Cut about 1" or 2" strips .080" wide (not critical) of about the same width as the main 50 ohm microstrip lines in the amplifier from thin copper or brass stock (.003" to .010"). Tin both sides of the strips and flick off excess solder. Make several tuning wands by cutting one end of a wooden toothpick square at the largest diameter. Using SuperGlue™, attach a square (.080" x .080") of the prepared tinned copper or brass to the curved end of the toothpick. Wipe off excess glue from the exposed side of the square and let dry.

Remove existing tuning stubs. Using an X-Acto™ knife, make a deep enough cut to disconnect tuning stubs from the main 50 ohm line. Be careful not to cut the thin brass lines. If you are unsure of possible damage to the bias lines, carefully check continuity or use a magnifier to do visual inspection before applying power. In some cases it pays to go through the agony of removing the stub completely as the correct new stub placement may overlap and cause problems.

Connect the amplifier to the signal source, attenuators, power detector and power supplies. Turn on the power and adjust input attenuation for as low an input as can be readily detected on the output. Start at the output and slide the tuning wand along (in contact with) the main 50 ohm line, watching for an increase in output. Note the maximum output reading obtained with the wand. Remove power and solder a square of the prepared material in the same position as noted by the wand.

Do not add solder. The tinning is normally sufficient to allow the new tuning stub to be held in place with the pointed end of a toothpick and then just touched with the soldering iron to reflow the solder. Turn on the power and verify that the output is as high or higher than obtained with the wand. Move the tuning stub if required to obtain results equal to or better than those of the wand.

Slide the wand over the previously attached new stub and if improvement can be made, attach another square. Continue this for the entire length of the main 50 ohm line until no further improvement is found. Increase the input power if working with a power amplifier and retune the output stage for maximum power. Be careful here not to mismatch the output so badly with the wand as to damage the FET.

The process can be very slow, with some stubs only gaining a fraction of a dB. In most cases it will take all of those small increases to get good results so don't expect to see major improvement with a few stubs. It may take four stubs per stage sometimes to get the maximum output.

Additional notes

Direct grounding of a microwave power device emitter/source is essential for proper operation. Any form of insulating grease can prevent full gain/power output from being obtained.

When mounting boards into enclosures, take care to ensure that the entire perimeter of the board is connected to the enclosure to prevent oscillation. 73

truly are the unsung heroes of amateur radio—I thank you all, and please do keep up the great work! There are people out there who really do appreciate it.

Aw, shucks... Wayne.

Roger Wendell WBØJNR. Wayne, in "Never Say Die" you asked if we'd like to hear you talk about something besides ham radio. You bet! How about the beauty of 3.5 billion years of organic evolution and what hams can do to save it? We don't need any more money schemes, dirty religions, or mindless hobbies—we need more of nature—the real world.

Roger, I've flown over the Pacific Northwest, so I've seen the ugliness of clearcutting our forests. I've seen the horrendous scars of strip mining. I'm also seeing the pollution of the radio frequencies, with around 30,000 rock music radio stations crowding my AM and FM dial, and 200 or so TV channels of mind-rotting crud. Our school system is crumbling. Our health care system is just as bad as our school system. Crime, drugs, welfare, and so on. Yes, we've made a real mess of our states, country and planet and we're trying to figure out how to go out and spread it to other planets. So what do we do, knuckle under and try to cut as big a piece of the pie as we can for ourselves, and to hell with the mess we make doing it? Or do we fight? But how can you fight City Hall? I've already proposed a way we can secretly infiltrate the "system" and start changing it, working from the inside. Roger, we hams are 700,000 strong, but only if we're working together. As individuals we're of no significance. Yes, as small a group as we are—we have the potential to change our cities, our states, our country, and then the world. Our foes are entrenched interests, apathy, and indifference. Our strength is a never-say-die attitude. Motivation. Determination. Perseverance. Roger, 700,000 people can be an army... Wayne.

Cliff Gieseke W4ZFL. UFOs are a topic I've been fascinated with since the early '50s, when I was first

Low Power Operation

Michael Bryce WB8VGE
P.O. Box 508
Massillon OH 44648

This month, I have some more odds and ends for you. These circuits and tidbits may help you enhance the performance of your QRP equipment.

A&A Engineering RIT modifications

The first project comes from John Best, Sr. WA1YIH. John took the RIT circuit for the MFJ QRP monobanders and modified it to work with the Gary Breed K9AY/A&A Engineering 30 meter rig. The original circuit appeared in *73's* "QRP" column for November '95. Here is John's modification:

"I modified the RIT circuit for the MFJ rigs to work with my A&A Engineering QRP transceiver. I used a Radio Shack IC board, 276-159, and ugly construction.

"To modify the rig, you have to remove the fine-tuning control. The fine-tuning control connects to the main tuning circuits. The wire that goes from the main tuning to the fine-tuning is removed and hooked to R2 (the 470 ohm resistor). The wiper of the fine-tuning is grounded. One side of the fine-tuning is connected to pin 2 of the 4066. The rest of the circuit is self-explanatory."

John reports that he gets approximately 800 Hz offset on either side of the RIT control center position. John's RIT indicator is pretty simple. He used a dual-colored LED, Radio Shack™ #276-025, and a DPDT switch.

John says, "I use the green as a rig power indicator as well as RIT off, and the red for RIT on."

With the fine-tune control out of the circuit, I would suggest you replace the original single-turn tuning control with a multi-turn pot. I've seen these units listed as surplus for under 10 bucks. Also, if you favor one segment of the band over another, I would change the voltage divider used to drive the VXO. Expanding the range within a segment will give you super-smooth tuning. On the downside, it would be real slow to go from one end of the desired segment to the other.

Wimpy 386 audio

If you've ever built a QRP rig, it's a good bet you've used the LM386 audio amplifier. It's almost a standard part—every QRP builder should have one in his or her junk box.

However pleased you may be with your home-brewed or commercial rig using an LM386 for the audio output stage, you can be in for a shock if you compare it to another rig. Side by side, with the same LM386 audio driver, some QRP rigs are much louder. I noticed this several years ago at the annual Dayton HamVention QRP forum.

We were playing with a new commercial rig. The audio was very wimpy. In fact, with a room full of people fixing the world's problems, you could hardly hear anything from the speaker. The guy who had just purchased the rig mentioned that the reason was the LM386. "There's not much audio inside an LM386." At that time someone looking over our shoulders said his rig had more than enough audio, so much in fact you could easily hear it in this room full of people.

So, we connected his rig up to the same antenna. We tuned in a station on 40 meters. With the volume control up only to half-way, someone across the room yelled at us to "Turn that damn thing down so we can talk." Indeed, the LM386 in his rig was really spitting out the audio!

Now, there are only so many ways you can configure a LM386 audio amplifier. You can select the amount of gain produced by swapping out a capacitor, but you can't generate more gain than the device will produce. Since we were using the same antenna, that ruled out any gain produced by the RF section. Both rigs were based on a direct conversion receiver, so almost all of the gain of the rig had to be in the audio chain. Everyone seemed to narrow the difference down to audio preamplifiers before the LM386. That was several years ago. Here's some info I have since dug up about this unique chip.

First, if you have a choice, get the LM386 made by National Semiconductor. Although the LM386 is made by a wad of companies, the National devices seem to work better.

Everyone I've talked with has been under the that assumption the LM386 is a 1 watt audio amplifier, but it actually comes in a variety of different power levels. Fact is, some are rated for only 300 mW! You can tell by the number on the chip. An LM386-1 is rated for 250 mW, the LM386-3 is rated for 500 mW, while the LM386-4 is rated at 700 mW. National spec sheets say normal power output for this version is close to 1,000 mW.

There are two other problems with LM386 designs. One is

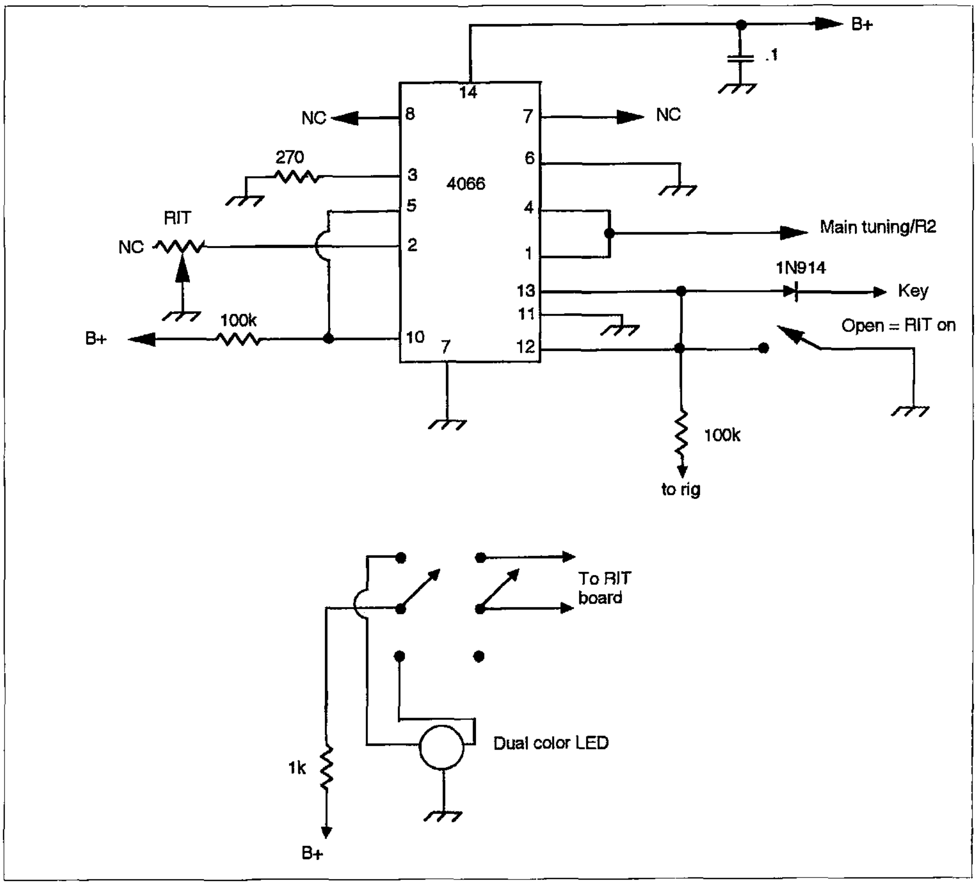

Fig. 1. WA1YIH's modified RIT circuit.

over-driving the amplifier. This is a very common problem, especially with home-brewed equipment. Let the gain of the amplifier do its job—you don't need to apply 200 mW of drive! Design your audio preamplifier so it provides the proper level for the LM386.

Another problem with some LM386 designs is a tendency to oscillate, or "motorboat." With rare exceptions, this can be cured by increasing the value of the decoupling capacitor on the VCC line of the LM386. It's also good practice to have this capacitor mounted as close as possible to the chip. Many designs show the value of this decoupling capacitor at about 220 µF. Increasing the value to 470 or 1,000 µF will usually do the job.

In really stubborn cases, a small value resistor, usually 10 or 22 ohms, may be inserted in series with the VCC line feeding the LM386. A 1/2 watt resistor should be used instead of the junk box 1/4 watt device.

An all-too-often overlooked item when fixing a wimpy LM386 is a poorly regulated power source. If your rig is running from a battery, and there is an internal 7812 regulator feeding the LM386, the regulator won't have enough overhead to regulate. This will cause the voltage supplying the LM386 to wander about. You can prevent this several ways.

First, you can run the LM386 from the input side of the regulator, assuming the input (supply) voltage is between 12 and 14 volts DC.

If this is not possible, you can use a voltage regulator with a lower voltage rating. A 7810 will have the necessary overhead when using a 12 volt supply, but just barely! A 7808 would be ideal, provided your circuit will operate at 8 volts. There *is* a 7809, but it's hard to come by.

If you need to increase the voltage of a 7808 regulator, there are two fixes. First, you can put a diode in series with the ground pin. For each diode, you will raise the output by .7 volts. Or, you can use a resistor connected to the ground pin. In both cases, you raise the ground pin slightly above ground, which causes the output voltage to increase. I should mention that neither way is the preferred method to increase the voltage of a three-terminal regulator. It's always best to specify the correct voltage regulator for the circuit under design.

Last month's schematics

Some of the schematics were missing from last month's column. Moving into a micro apartment has really put the screws to me. As things begin to settle down, I'll be able to get back into my routine. If you are interested in some of the missing schematics, drop me a line. Do be sure to send letters to my new address, P. O. Box 508, Massillon, Ohio 44648.

Out of all this madness, a 100 percent solar home will be constructed. A 4 kW peak solar array is planned. Also planned is a 65-foot free-standing tower, complete with some real antennas! The best part of it all is that by the time I'm done, the sunspot cycle should be taking off. Talk about good timing! 73

licensed as WN4ZFL and W4ZFL in Pensacola, FL, as a teenager. I teach foreign military personnel at the Defense Language Institute English Language Center at Lackland AF Base and last week I was introduced to a Turkish AF officer there who had an encounter with a UFO. About five years ago, he told me, he was in the front seat of an F-104 when his instructor in the back seat called his attention to an approaching disc-shaped bright light. It continued to approach them, and when it was quite close his instructor decided to initiate the ejection sequence. Before he was ejected, after being told to prepare for ejection in 10 seconds, he saw the UFO veer away from them, but too late to save the aircraft. The approach of the UFO to their aircraft was, fortunately for the pilots involved, witnessed by personnel in a control tower close to the runway.

Other DLIELC students have told me of UFO encounters over the years. While teaching all the military officers attached directly to the Colombian president (his personal pilot, security chief, protocol officer, a Navy liaison officer, and the colonel in charge of "La Casa Militar") a number of years ago at the Presidential Palace in Bogota, Colombia, I asked these officers one day when we were all together if they thought the most likely explanation for the more reliable, more substantial, credible reports was that we are being visited by extraterrestrials. Going around the conference table with this question I was fascinated when each officer responded with a "Yes." That's the only military group I've taught over the past 30 years that was so unanimous when asked such a question.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the June issue, we should receive it by March 31. Provide a clear, concise summary of the essential details about your Special Event.

FEB 8

CHARLESTON, SC The 24th annual Charleston Hamfest and Computer Show will be held at Stall H.S. near I-26 and Ashley Phosphate Rd., in North Charleston. Tailgating allowed. Talk-In on the WA4USN Linked Rptr. Sys. 146.79(-) Rptr. aboard the *USS Yorktown* and the 145.25(-) Rptr. near Summerville. Tickets will be sold Sat. morning at the door; $5 for adults. Children under 12 admitted free. Pre-reg. tables are $8 per 8 ft, $10 at the door as long as they last. Make check payable to *C.A.R.S. Hamfest Committee*, and send with an SASE, to *Jenny Myers WA4NGV*. Table reservations must be received before Jan. 24th. VE Exams on site starting at 12 Noon. Walk-ins. Bring original and copy of your license, any CSCEs you have, and two IDs, one with a photo. For exam info, call *Ed Frank KC4OOZ, 610 Longstreet Cir., Summerville SC 29483. Tel.(803) 871-4368;* or *Doc W4MUR, (803) 884-5614* or E-mail: *efrank@charleston.net*. The Hamfest contact is *Jenny Myers WA4NGV, 2630 Dellwood Ave., Charleston SC 29405-6814. Tel. (803) 747-2324,* or E-mail: *brycemyers@aol.com*. VE Exams are also given monthly on each 3rd Saturday, at Trident Tech College, Rivers Ave., North Charleston, Bldg. 630 at 9 AM. Contact *Ed Frank KC4OOZ, (803) 871-4368.*

DEARBORN, MI The Michigan Antique Radio Club will host its Swap Meet at the Armenian Hall on Ford Rd. Open to the public 8 AM-Noon. Adm. $2 per person. A Silent Auction, Equip. Contest, and a Donation Auction will be featured. Contact *Jim Clark at (517) 349-7187.*

FEB 9

MANSFIELD, OH The Mansfield Mid*Winter Hamfest/Computer show will be held by the InterCity ARC, Inc., at the Richland County Fairgrounds in Mansfield. Doors open at 7 AM. Tickets $4 in advance, $5 at the door. Tables $9 in advance, $12 at the door, if available. Advance orders must be received and paid by Jan. 13th. Send requests, payments, and SASE to *Pat Ackerman N8YOB, 63 N. Illinois Ave., Mansfield OH 44905;* or phone *(419) 589-7133 after 1 PM EST. Talk*-in on 146.34/.94 W8WE.

FEB 13 and 27

FORT WORTH, TX The Lockheed ARC and the Kilocycle Club of Ft. Worth will sponsor VE Exams for all classes at the Lockheed Rec. Area Facility located at 2400 Bryant Irvin Rd. Exams start at 7 PM. G.R.D.L. testing done by appointment only. Call *Ted Richard AB5QU at (817) 293-6745.*

FEB 14–16

ORLANDO, FL The OARC of Orlando will host the Orlando HamCation and Computer Show, and ARRL North Florida Convention at Central Florida Fairgrounds. Set up Fri. 9 AM–5 PM; open to the public Fri. 5 PM–9 PM, swap tables only. Sat. 9 AM–5 PM and Sun. 9 AM–4 PM. 150 commercial exhibits. Largest tailgate area in FL. RV overnite parking $16. Adm. $6 advance, $9 gate. Free parking. Swap tables $25/Tailgate $15 all 3 days. For advance tickets and info, contact *Orlando HamCation, P.O.*

Box 547811, Orlando FL 32854. E-mail: *kd4jqr@aol.com.* Web Page *www.cycat.com/users/oarc.* Forums: NASA Astronaut, Slide/Photo Exhibit of Lightning Storms, ARRL, APRS Demo by Bob Bruninga, WX Downloads, WX Equip. for the Home, Shortwave Listening by Bob Grove, pub. *Monitoring Times*; Build a VHF SWR Meter; Grounding for Lightning; Antenna Workshop; Radio Testing, and more.

FEB 15

HARRISBURG, PA The Harrisburg ARC will hold its Winter Hamfest 8 AM-Noon at the Oberlin Fire Hall, Oberlin PA. General adm. $2. Inside Tables $8 ea. Tailgating $1 per space. Dealer Set up at 6 AM. VE Exams start at 9 AM. Talk-in on 146.76. For info and table reservations, phone the *HRAC AnswerLine* at *(717) 232-6087.*

HORSEHEADS, NY The ARA of the Southern Tier will present a Hamfest at the New York State Armory, 128 Colonial Dr., 7 AM-3 PM. There will be dealer displays of new equipment and an indoor Flea Market area. Tables will be available on a first-come basis. VE Exams start at 9 AM. Contact *Jack Slocum, 410 Shelbourne St., Horseheads NY 14845. Tel. (607) 739-4866.*

TRAVERSE CITY, MI Cherryland ARC will hold their 24th annual Swap-n-Shop at Immaculate Conception Middle School, 8 AM–Noon. VE Exams following the Swap at 1 and 4 PM. Talk-in on 146.86. For more details call *Joe W8TVT* at *(616) 947-8555*, or *Chuck W8SGR* at *(616) 946-5312.*

FEB 16

BRIGHTON, CO The Aurora Rptr. Assn. will hold its 15th annual Swapfest at the Adams County Fairgrounds, 9755 Henderson Rd., 8:30 AM–2 PM. For details, contact *Chris Knauer KB9CCR, (303) 403-1883;* or E-mail at *cknauer@skywam.org;* or write to *Aurora Repeater Assn., c/o Janice Christopherson, 4376 S. Argonne Way, Aurora CO 80015.*

NEW WESTMINSTER, BC, CANADA The Burnaby ARC, VE7RBY, will hold the "Burnaby ARC 10th Annual Fleamarket" at New Westminster Armouries, 6th St. and Queens Ave., 10 AM–2 PM. Set up at 9 AM. Talk-in on VE7RBY 145.35(-) or 442.85. For info and tables, phone between 7 PM–9 PM PT: *Harry VE7HNC, (604) 530-3962; Graham VE7ABC, (604) 530-1907; packet VE7ABC@VE7KIT;* or *Rick VE7HRL, (604) 464-0768.*

FEB 22

LAPORTE, IN The LaPorte ARC "Cabin Fever Hamfest" will be held 8 AM–2 PM at LaPorte Civic Center. Adm. $4; tables $5 ea. Talk-in on K9JSI 146.610 (131.8PL), 443.900 (131.8PL) and 146.520 simplex. For details contact *John N9ROH, LPARC, P.O. Box 30, LaPorte IN 46352.*

MILTON, VT The Radio Amateurs of Northern Vermont will sponsor the Northern Vermont Winter Hamfest 8 AM–3 PM at Milton H.S., Route 7. Features include Flea Market, Auction, Dealers, Book Sales, Forums, and more. VE Exams will be given at 9 AM and 2 PM. Commercial Exams at 2 PM. Adm. $3, free for under 18 years. Tables are free while they last. Call for large setups. Talk-in on 145.15 Rptr. Contact *W1SJ* at *(802) 879-6589. E-Mail: wb2jsj@vbi.champlain.edu. Web Site: http://www.together.net/~fflynn/milton.html.*

FEB 23

CUYAHOGA FALLS, OH The Cuyahoga Falls ARC will host its 43rd annual Hamfest at Emidio's Party Center, 48 Bath Rd., 8 AM–2 PM. Free parking. Talk-in on 147.87/.27 W8VPV. Adm. $4 advance, $5 at the door. Reserve tables by Feb. 8th, $8 advance, $10 at the door, if available. Contact *Bob Recny N8SQT, 496 Orlando Ave., Akron OH 44320-1243.* Tel. *(330) 864-5810;* FAX *(330) 864-5879;* E-mail: *hamfest @neo.lrun.com.*

LIVONIA, MI The Livonia ARC will present its 27th annual Swap 'n' Shop, 8 AM–3 PM, at the Dearborn Civic Center, Dearborn MI. VE Exams. Talk-in on 144.75/.35. For info, send a 4x9 SASE c/o *Neil Coffin WA8GWL, Livonia ARC, P.O. Box 51532, Livonia MI 48151-5532;* or call the Club Phone Line, *(313) 261-5486.*

MAR 1

ABSECON, NJ The Shore Points ARC will sponsor its 15th annual hamfest, "Springfest '97" at Holy Spirit H.S. on Route 9, starting at 8 AM. Set up at 6:30 AM. Flea Market, outdoor Tailgating (weather permitting). Talk-in on 146.385/.985 PL 146.2 Hz. For info, write to *SPARC, P.O. Box 142, Absecon NJ 08201;* or call/FAX *(609) 653-1987.*

PARSIPPANY, NJ The annual North Jersey Hamfest, sponsored by Split Rock/West Morris Radio Clubs will be held at the PAL Bldg. on Smith Rd. Talk-in on 146.985/.385. For info or reservations, call *Bernie WB2YOK*, Fax/Voice *(201) 584-5399 24 hrs.;* Online *75503 ,3221@compuserve .com.*

MAR 15

KNOXVILLE, TN The Shriners of the Kerbela AR Service will sponsor the Kerbela Hamfest at the Kerbela Shrine Temple, 8 AM–4 PM. Adm. $5. Indoor vendor tables $8 ea., plus adm.; outdoor tailgating spaces are $3 plus adm. Set up at 4 PM–9 PM Fri, and 5 AM–8 AM Sat. Talk-in on 144.83/145.43, or 146.52 simplex. Smoking in designated area only. Contact *Paul Baird K3PB, 1500 Coulter Shoals Circle, Lenoir City TN 37772.* Tel. *(423) 986-9562.*

SPECIAL EVENT STATIONS

FEB 8–10

ST. PETERSBURG, FL The QCWA Golden Anniversary QSO Party will be open to all Amateur Operators, world wide, 1400 UTC Feb. 8th -0600 UTC Feb. 10th; and 1400 UTC Mar. 8th–0600 UTC Mar. 10th. For rules, send request and a business size SASE to *J. Frederick Strom K9BSI, Activities Mgr., 233 34th Ave. North, St. Petersburg FL 33704-2241.* All logs must be received no later than Apr. 1st, 1997. Mail Feb. logs to *Arthur Monsees W4BK, 420 Bay Ave., Apt. 1521, Clearwater FL 34616.* Mail Mar. logs to *Donald Bice W4PCO, 5511 18th Ave. North, St. Petersburg FL 33710.*

FEB 14, 15, 16

MARQUETTE, MI Hiawatha ARC K8LOD Up 200 Sled Dog Race. 20–80 meters, General. For a certificate, send an SASE to *N8BGA, 21 Smith Lane, Marquette MI 49855.*

FEB 15–16

ALEXANDRIA, VA The Mount Vernon ARC will operate K4EC 1600Z–2200Z Feb. 15–16 to commemorate George Washington's birthday. Operation will be in the lower General 80–15 meter phone subbands and in the Novice 10 meter subband. For a certificate, send your QSL and a 9x12 SASE to *MVARC, P.O. Box 7234, Alexandria VA 22307.* For more information, contact *Mary Pat Nowack KE4QWK, 703-684-8793.*

Communications Simplified, Part 14

Peter A. Stark K2OAW
P.O. Box 209
Mt. Kisco NY 10549

Although we can calculate the VSWR once we know the load impedance, in practice it is a lot easier to measure it directly. The two most common instruments used are an inexpensive SWR bridge and a much more expensive (and more accurate) device called a through-line wattmeter. The Bird ThruLine meter is the most common brand name of the latter. Both of these work on pretty much the same principle; **Fig. 1** shows how the SWR bridge works.

The meter has a metal trough running from one end of the case to the other, with the transmitter and antenna connectors at opposite ends of the case. Running through the trough are the three wires labeled **A**, **B**, and **C** in **Fig. 1.**

Wire **A** carries the signal from the transmitter to the antenna. Wires **B** and **C** are close to it, but not touching; they are called *sensing wires*.

Let's look at wire **B** first. Because **B** is right next to **A**, there is a small capacitance between the two. This causes wire **B** to pick up a small amount of signal from **A**. But as current goes through wire **A** to the antenna, it also generates a small magnetic field. Wire **B** is in that field, and therefore picks up a small amount of signal from the magnetic field as well. The polarity of the signal picked up through the capacitance does not depend much on which way the signal is going, but the polarity of the inductively coupled signal does. For an outgoing signal from the transmitter to the antenna, the two voltages add, whereas for the reflected signal, they cancel. Diode D1 therefore gets a signal proportional to the outgoing or forward signal, but ignores the voltage from the reflected signal. In the same way, diode D2 gets a signal proportional to the reflected signal. The two voltages are then rectified and filtered by the two diodes and capacitors, and fed through the FWD-REV switch to the meter.

The secret to the measurement is in the meter's scale calibration, shown in **Fig. 2**. To use the meter, we first connect it to the transmitter, set the FWD-REV switch to the FWD or Forward position

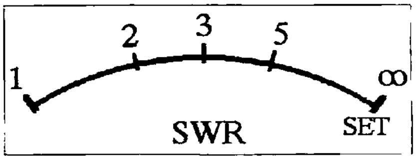

Fig. 2. SWR bridge meter scale.

and turn on the transmitter. Then we set the CALibrate control so that the meter reads full-scale; there is usually a small SET mark at the right end of the scale. Regardless of how much power or voltage the transmitter is sending out, this calibrates the SWR bridge to that level.

The next step is to switch the FWD-REV switch to the REVerse setting (without touching the CALibrate control). If all of the power is reflected from the antenna, indicating an infinite VSWR, the reverse voltage is the same as the forward voltage, and thus the meter will read full-scale. So the full-scale end of the scale reads infinity. If, on the other hand, the antenna is a perfect match, then the reverse voltage is zero and the VSWR is 1; hence the left end of the scale reads 1.

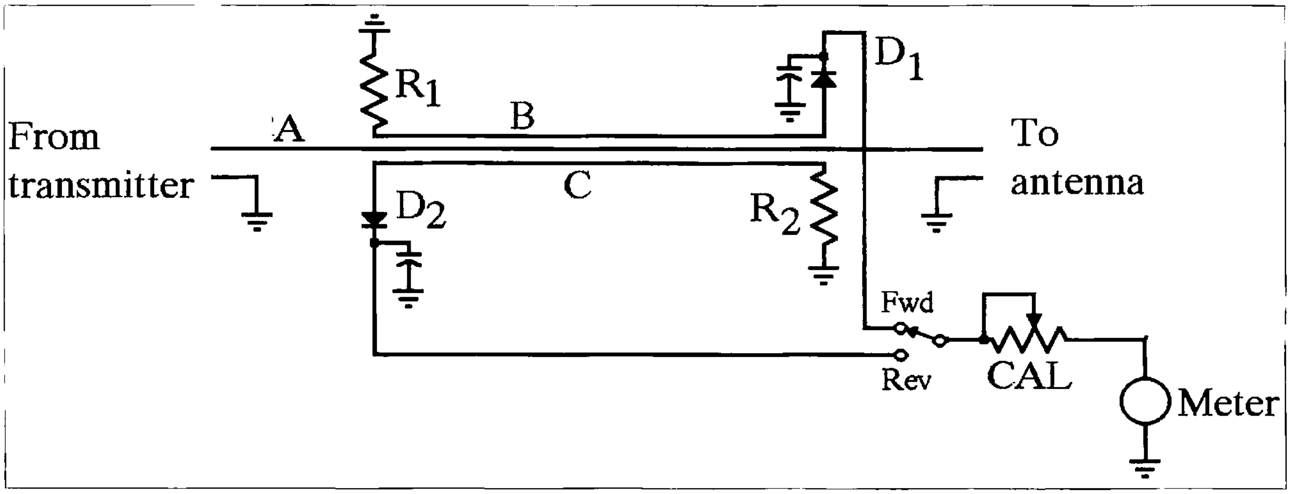

Fig. 1. An SWR bridge.

At the midpoint, the reverse voltage is exactly half of the forward or outgoing voltage. For example, if the outgoing signal is 10 volts and the reverse is 5 volts, the VSWR is then:

$$VSWR = \frac{Vmax}{Vmin}$$

$$= \frac{10 + 5}{10 - 5} = \frac{15}{5} = 3$$

so the midpoint reads 3. Since VSWR above 3 is generally considered quite bad, the right half of the scale is usually colored red.

A typical SWR bridge costs $20-$30, and covers a fairly limited frequency range. For more accurate measurements, many professionals use the Bird ThruLine Wattmeter. This meter works on the same principle, but instead of having two separate sensing wires, two diodes, and a switch to select them, there is one sensing wire and its diode, mounted in a rotating assembly called a *slug*. The slug has a printed arrow on it, and you rotate it to measure the forward or reverse voltage. The meter is calibrated in watts, rather than in VSWR. Because the reading depends on frequency and power, Bird makes several dozen different slugs for various power and frequency ranges. This makes the power readings quite accurate, but the disadvantage is that you have to calculate your own VSWR from the forward and reverse power readings. (In practice, many technicians take the easy way. If the forward power is "big" and the reverse power is "small," then they are happy!)

One application—a waveguide

The idea that a line shorted at one end can appear open at the other, and vice versa, has some interesting applications. Consider microwaves, for instance.

Microwaves are radio waves that have a very high frequency, typically more than several gigahertz. This also means that they have a very small (micro) wavelength. For example, a signal at 10 GHz has a wavelength of about 1/4". At these frequencies, signals travel only on the surface of wires, not inside them; this is the so-called *skin effect*. A much more severe problem is that most insulators do not

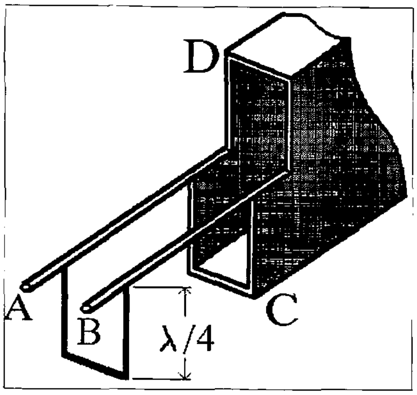

Fig. 3. Making a waveguide.

work very well at these frequencies—they are too lossy. So it is difficult to build a cable to carry them any great distance.

But suppose you used a pair of uninsulated wires (**A** and **B** in **Fig. 3**) held up by a wire loop, as shown at the left of the figure. If the wire loop was exactly 1/4 wavelength long, then its top would appear open even though the bottom is shorted. In other words, a perfect insulator made of metal!

In practice, this is a tad tough to fabricate. But since you can place these wire loops as close together as you want, there is no reason why they cannot be made into the continuous trough shown as **C** in **Fig. 3**. To prevent rainwater from collecting inside, we place another identical trough (**D**) above it, giving us a rectangular pipe called a *waveguide*. The signal simply travels along the inside edge of the pipe, roughly in the middle of the long side, which is now 1/2 wavelength long (1/4 wavelength from the middle toward each end).

The frequency at which the long side of the waveguide is exactly a half-wavelength long is called the *critical frequency*. Frequencies lower than the critical frequency can't make it through the waveguide because the distance from the midpoint to the edge is too small—they get shorted out by the edge of the loop. But frequencies *above* the critical frequency can make it through, simply by traveling a bit closer to the edge.

Most waveguides are fairly small. But if you've ever driven through a long tunnel, you've been inside a large waveguide. You may have noticed that your AM radio goes dead almost as soon as you enter the tunnel, whereas your FM radio only gradually fades out as you go in. The reason is that the typical tunnel is too small to let AM broadcast signals through. Since the typical AM station has a wavelength of 600 feet or more, the tunnel would need to be more than 300 feet (a half wavelength) in diameter to let the signal in. So AM signals simply don't make it into the tunnel. FM broadcast station frequencies, on the other hand, have a wavelength of about 10 feet, so even the smallest tunnel will let them through.

Tunnels don't really make good waveguides, though, because they are not made of a good conductor. Underwater tunnels are made from short sections of steel pipes, with waterproofing compound joining them so they do not leak. This waterproofing insulates the sections from each other, so FM signals, though they get partway into the tunnel, cannot really travel all the way through. Still, it makes an interesting example.

The idea of radio waves getting through holes is similar. For example, if you wanted to shield a room to prevent radio waves from getting in or out, you could completely encase it in a solid sheet of copper. But this isn't necessary—you can use copper sheet with holes in it, as long as the holes are substantially smaller than 1/2 wavelength. Likewise, the metal sheet covering the window in a microwave oven door has holes that we can see through. But the holes are much smaller than the microwave wavelength, and so the microwave energy cannot get through.

Another application—a stub

A stub is simply a short piece of transmission line. For example, suppose you are trying to receive a particular station, but another strong nearby station is causing interference in your receiver. You therefore decide to filter out the interfering station and keep it out of your receiver.

The simplest (though not necessarily the best) solution is to connect a 1/4-wavelength stub in parallel with your receive antenna. If you leave the far end open, the end connected to your antenna terminals will act as a short and short out the interfering signal. You must keep in mind the velocity factor of the cable to calculate the correct length; in practice, it's probably a good idea to cut the cable a bit too long, and then cut off tiny pieces while observing the interference, until the length is just right.

Transformers for impedance matching

Quite often you need to match one impedance (for example, a 75-ohm cable) to another (such as a 300-ohm antenna). This particular case is a common one with TV antennas; many TV antennas are designed for 300-ohm twin-lead, but used with 75-ohm coax cable.

In this example, there is more than just impedance matching at stake. Coax cable is unbalanced (the signal travels on the inner wire, while the outer shield should be at ground potential), whereas most TV antennas are balanced (both connections carry the signal, but out of phase with each other.) Such transformers are also often called *baluns*, because they connect between a balanced and an *un*balanced device.

Matching transformers are readily available just for this purpose. The ones for TV use are cheap because only low power is involved; the ones for transmitting applications must handle the full transmitter power and so they are bigger and more expensive.

Fig. 4 shows the wiring of a typical TV balun transformer designed to match 75-ohm coax to a 300-ohm balanced antenna. The transformer consists of two wire windings, wound near or over each other. Since the impedance ratio of the two windings of a transformer is the square of the turns ratio (the ratio of the number of turns on the primary and secondary), for a 300-to-75-ohm impedance match (a ratio of 4-to-1), we need a turns ratio of 2-to-1. So the 300-ohm side of the transformer has twice as many turns as the 75-ohm side.

The matching transformer in **Fig. 4** has the advantage of being usable over a wide range of frequencies. But if you only need to match at one specific frequency, you can use a length of transmission line instead.

We've now learned that a 1/4-wavelength cable can change a short into an open, or vice versa. But there's more to it than that. If the characteristic impedance of the cable is Z_0 and the load on its output is Z_{load}, then the impedance Z_{in} you see looking into the cable is:

$$Z_{in} = \frac{Z_o^2}{Z_{load}}$$

Notice that this makes sense: if Z_{load} is an open (infinite impedance), then Z_{in} is a short (zero impedance). If Z_{load} is a short (zero impedance), then Z_{in} is an open (infinite impedance). And if Z_{load} is equal to Z_0, then Z_{in} is also Z_0. So far so good.

But we can take this equation and rewrite it as:

$$Z_o^2 = Z_{load} \times Z_{in}$$

$$Z_o = \sqrt{Z_{load} \times Z_{in}}$$

So if we want to connect a load Z_{load} of 300 ohms to a 75-ohm input Z_{in}, all we have to do is connect a 1/4-wavelength line between them whose characteristic impedance is:

$$Z_o = \sqrt{Z_{load} \times Z_{in}} = \sqrt{300 \times 75}$$

$$= 150 \text{ ohms}$$

With the 300-ohm load on a 1/4-wave section of line having a 150-ohm characteristic impedance, the input into the line will look like 75 ohms, a perfect match.

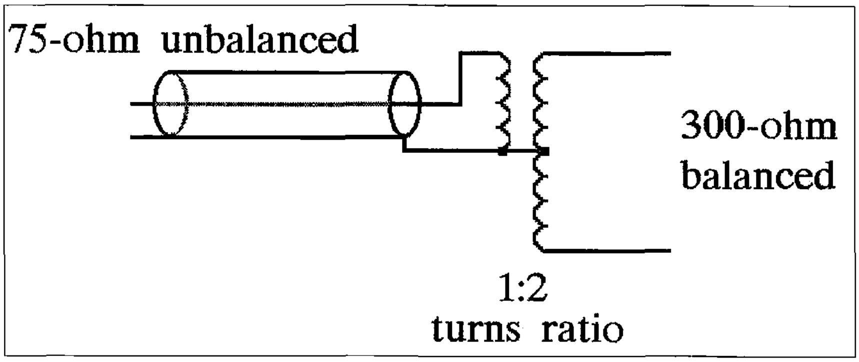

Fig. 4. 300-75-ohm balun.

There are two catches, of course—this will only work at the one frequency that the line is cut for, and you cannot mix a balanced line with an unbalanced line. So this is totally unusable for the typical TV application. But it is perfectly suited for those single-frequency applications in communications.

Last thoughts

There is one other idea that should be covered, but that didn't somehow fit into any of the previous sections. In a balanced transmission line (such as the 300-ohm twin lead used in TV antennas), it's obvious that the signal travels along both conductors. But many people believe that in coax the entire signal travels only along the inside conductor, and the shield is there only for the ride, so to speak—to keep outside signals out, and inside signals in. Not so.

If you place a load, such as a resistor, at the end of a line, the only way to get a current to flow in the resistor is to have both ends of it connected to *something*. Whatever current flows into the resistor from the center conductor must flow out the other end, and into the shield. So the shield takes an active part in the process. This will be an important concept in the next article in this series, when we talk about antennas. An antenna cannot connect just to the center conductor of the coax because then the current has nowhere to go. There must be a solid connection from the coax shield to some active part of the antenna so that current can return along the shield.

Summary

Our treatment of transmission lines has been a very brief, simplified one. There's a lot more to this subject. For one thing, we've assumed that our transmission lines have no loss. That's not true; the loss changes the results somewhat, and usually must be taken into account.

More important, even though we've used the symbol Z in our calculations to keep things general (and to use the same symbols as most other books and articles), we've ignored the fact that these are really impedances—we've made believe that all the Z's have been pure resistances. That makes things simple, but is not exactly realistic. But at this point I will use the standard excuse you'll find in many books: "More advanced treatment is beyond the scope of this article."

QRP T-R Circuit

It's simple and versatile.

Mark L. Meyer WUØL
14153 West First Drive
Golden CO 80401

Have you been looking for a simple T-R circuit for your QRP transceiver project? I too was faced with this problem recently. I wanted something that was simple, would work for several different bands, and would not add significantly to battery drain.

Most of the current crop of QRP designs and kits are of the single-band variety and use the L-C series traps method of automatically isolating the receiver input from the antenna when the transmitter is keyed. This is a great and simple method; however, the L-C network is specific for each separate band. I was working on a multibander so I wanted a circuit that would work for all bands without modification or duplication. I also wanted near QSK performance for quick changeover, not between CW characters but between words or pauses. I decided what I really needed was a reed relay circuit that would utilize a normally closed contact to keep the antenna connected to the receiver with no current flow at all during receive periods.

Reed relays have very fast switching times and also have high coil resistance. This means low current flow, especially compared to what a rig draws anyway on transmit. These relays typically draw only 15 milliamperes or less operated at 12 VDC.

The circuit

Fig. 1 shows the circuit I developed. The circuit is activated from the key line on your rig. This is the line that goes to ground potential when your rig is keyed. This comes straight from your key jack; either your hand key or your keyer, when activated, causes this line to go to ground. This in turn causes a keying transistor to turn on, applying 12 volts to various parts of your transmitter circuitry.

In **Fig. 1**, nearly the same thing happens as in your transmitter. When A is grounded, Q1 turns *on*. This applies +12 volts to the coil of RLY1. Since this is a very fast relay, it immediately opens the contact separating the receiver from the antenna. Note that the Q1 circuit does not contain any timing or shaping capacitors like your switching transistor in your transmitter circuit does. This is because we want RLY1 to pick up immediately before the transmitter is turned on. Otherwise we may pump some transmitter power into the receiver, causing some serious problems!

Q1 also applies voltage to capacitor C1 through resistor R1, causing it to charge. This is the dropout timing circuit. When Q1 returns to normal, C1 discharges through R1 and the relay coil. C1 and R1 are chosen to keep the relay pulled in through a normal string of dits and dahs, but to drop out on pauses or between words.

If you wish a longer dropout period, simply increase C1 to 330 µF or 470 µF. Reduce C1 for a quicker QSK type response. R1's purpose is to make sure that RLY1 receives full voltage immediately (not dragged down by charging C1) upon energization, so pickup is quick.

The relay

The relay specified has a 1,000 ohm

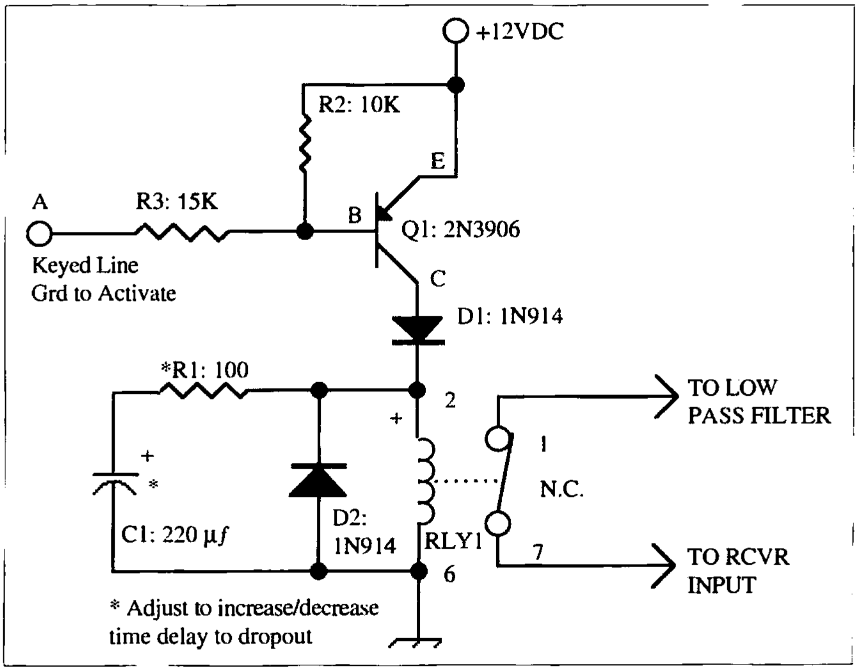

Fig. 1. T-R antenna changeover circuit.

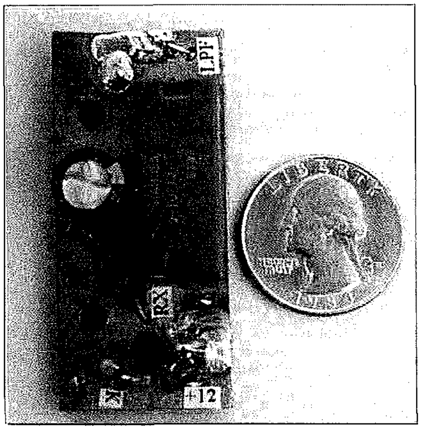

Photo A. The T-R board shown before installation, resting on top of the case for the rig.

coil. Energized, it will draw about 12 milliamperes. I am currently using a relay with a coil that measures 800 ohms and the values specified are right for my normal keying speeds. Feel free to experiment with whatever relay you chose by varying C1 and R1, but do not lower R1 very much because you want RLY1 to pick up immediately.

A word about reed relays– they come a several different forms. Most have one normally open contact. You want one with a normally closed contact for this circuit, so check it out with your ohmmeter. Also, some reed relays have a built-in suppression diode (D2). In this case you don't need to include D2 in your circuit (but it won't hurt if you are unsure). D2 provides a safe path for the energy stored in the coil to dissipate when the coil is de-energized. Some reed relays are polarized. Be sure the (+) mark is towards Q1 if the relay you use has a polarizing mark.

Test your relay by connecting your ohmmeter across the contacts and energizing the coil from a 12 volt supply. Watch for polarity before you connect the coil to the supply. When you energize, the contact should open and the meter reading go from zero to infinity.

Reed relays have long life expectancies. The relay specified is good for 100 million operations when switched *dry*. (That *dry* means when the contacts do not have to switch current other than very small signal values, like we are doing.) For the worst-case scenario, if you transmitted 24 hours straight every day for an entire year, at 15 wpm, using full QSK, you would just barely exceed 100 million operations. For us less active

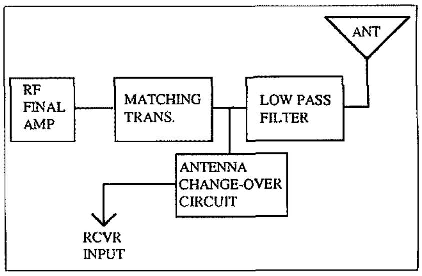

Fig. 2. Hookup.

operators, this relay should have a long life span.

Construction and testing

All parts other than the relay are garden variety. Just about any small PNP silicon switching or small signal transistor will work for Q1. The diodes are silicon small signal or even small rectifier diodes. C1 should have a 25 volt rating to be safe.

I built my T-R circuit on a little scrap of printed circuit board measuring about 2 inches by 1 inch. I just gouged out some isolated pads for each connection pad and drilled holes with my Dremel™ tool. A small perfboard or Radio Shack™ pre-drilled project board (RS #276-159) will work great. The Radio Shack board will accept the relay pins directly, making things easy.

Hookup and testing are easy. Connect a 12 volt supply to the circuit. Again hook up the ohmmeter across the contacts. Ground "A" and see that the contact opens immediately but closes back after a short delay. You will need an analog ohmmeter to see the pickup and delay because most digital meters take a while for the reading to change. Then hook a jumper from your key line in your rig to "A." Send a string of dots and dashes. You should aim to have the relay stay picked up between characters but to drop out on pauses. If your operating habit is such that you would like the relay to hang in between words, increase C1 substantially. Otherwise small changes will take care of things.

Be sure that when messing with your rig you have a dummy load connected or you remove the 12 volt supply from the output transistor. You wouldn't want to blow up the final because you didn't have an antenna connected. Now build the circuit into your transceiver. Connect one side of the relay contact to the spot between your low-pass filter and the

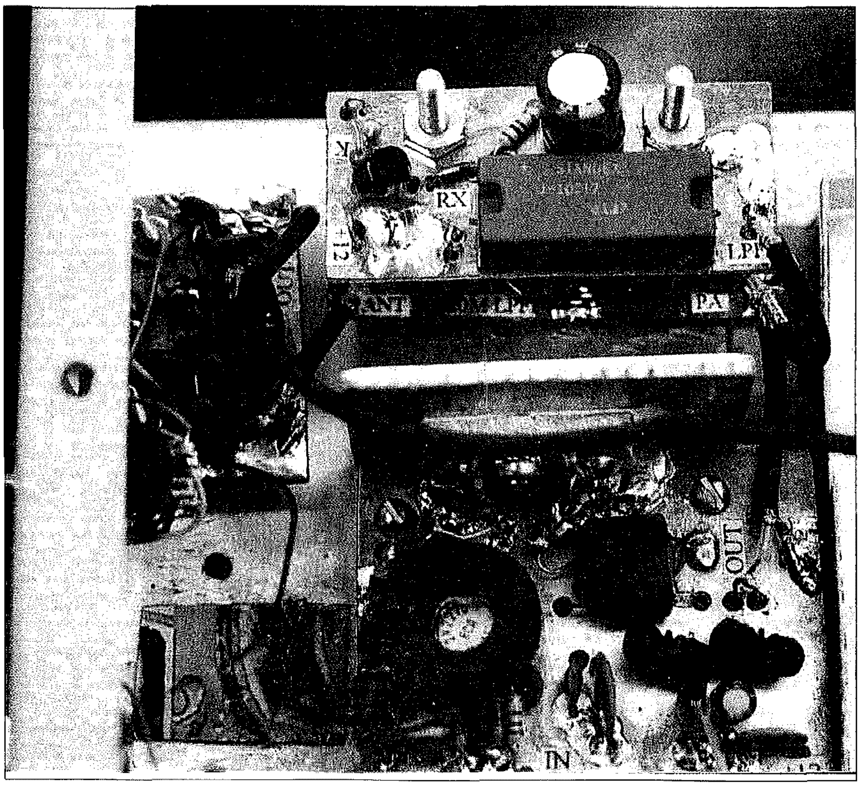

***Photo B.** The T-R Board (upper center) installed in a portable rig. Directly below are the PA and driver boards. The low-pass filter is located on a board underneath the T-R board.*

power amplifier matching transformer, or between the low-pass filter and the power amplifier itself if no matching transformer is used. The other side goes to the receiver input. That's it!

You now have a very simple circuit that works great. It works for any of the HF. bands without modification, and you learned a little about circuit design in the process.

Parts List			
Relay	RLY1	Reed relay with Normally Closed contact	Newark #65F2276 or Mouser #433-D31B510
Diodes	D1,D2	General purpose	1N914 or 1N4148
Resistors	R1,R2,R3	1.4 watt	
Transistor	Q1	Any small general purpose PNP	2N3906
Capacitor	C1	220 uF, 25V

NEVER SAY DIE

Continued from page 55

64-page book of 60 of my editorial segments which hadn't yet been in *73*.

All this got started with my first RTTY newsletter, 45 years ago. I was inspired by the John Campbell W2ZGU editorials in *Analog*. Well, it used to be *Astounding Stories*. Unlike any other magazine I've seen, John wrote long editorials about anything he thought the readers might find interesting. I started reading his editorials around 1938, when I got interested in science fiction. Unfortunately John smoked, so he died relatively young, robbing the world of a lot of entertainment. If you find yourself near an antiquarian book store, look for a 1966 Doubleday book of John's collected editorials. You'll treasure it.

As John wrote in his March 1965 editorial, "Editorially I shall continue to try to investigate the nature of the stuffing in any suspiciously bulging shirts around. My business is directly concerned with the progress and achievement of the human race; any orthodoxy that tends to sidetrack or otherwise impede progress is interfering with my business, and I'll do what I can to sabotage them." You could do worse than follow in his footsteps. Just because a lot of people believe something doesn't make it true. In fact, the likelihood is that it isn't true.

Are you still just sitting there? Get cracking! Let's see what you can do. But please be sure to do your homework before you write. Know what you are writing about.

Placebos

Back when cortisone first became available an arthritis patient pleaded with her doctor to let her have some. The doctor said that, well, cortisone was hard to get, but he had a new remedy that was supposed to be almost as good. For four weeks he gave her cortisone shots, telling her it was the new remedy. She showed no improvement. Then he said that the cortisone had finally come in and showed her the ampule. But he switched to a sterile saline solution for her

In Search of Higher Power

... and a safe connection for it.

Robert W. Vreeland W6YBT
45 Maywood Dr.
San Francisco CA 94127

Recently I saw an ad for a neat little 500 watt PEP mobile amplifier. It looked like a great way to get in some really high powered 75 meter mobile. Then I thought about how I would get power from the car battery to the amplifier, which required 13.8 volts at 80 amps peak. Supposing that the total resistance of the cables plus contact resistance was 0.02 ohms (not an unreasonable assumption), the peak IR drop would then be 80 times 0.02, or 1.6 volts. This would leave 13.8 minus 1.6, or 12.2 volts to power the amplifier; not good, but I could probably live with it.

Next I thought about the I^2R power lost in the cables and connections. It would be 80^2 times 0.02, or 128 watts! This might even start a fire. The problem is not with the amplifier, but rather with the method of connecting it to power. Obviously, high power 12 volt equipment requires special care in installation.

The options

What about a solid-state 120 volt powered linear for home use? There are several on the market, but they are all very expensive. One in particular caught my eye. It is rated at a full kilowatt output at 100 percent duty. What a beautiful unit! In order to achieve such high output, they used 48 separate MOSFETs. No wonder it costs well over $4,000.

There are a number of vacuum tube linears in the under-$2,000 price class. What do the vacuum tube people know that the solid-state manufacturers may not? More than 50 years ago they learned that the way to increase output is to raise the voltage, not the current. High current means high component losses.

MOSFETs

Probably the first really good RF power transistors were made by the Amperex division of Phillips. With a 28 volt supply, their BLX14 put out 50 watts PEP. The BLX15 put out an astounding 150 watts using a 50 volt power source.

Most manufacturers saw more money in the 12 volt mobile market and neglected the high voltage high efficiency field, but at least one manufacturer has introduced a line of high power RF MOSFETs designed for use with a 50 volt supply. This is definitely a step in the right direction. The catch is that inside what looks like a single transistor there is a whole bunch of separate MOSFETs, each with its own gate and source connecting wires—a very expensive type of construction.

"Most manufacturers saw more money in the 12 volt mobile market and neglected the high voltage high efficiency field."

What about really high voltage MOSFETs? There are 600 and even 800 volt models available. They are used in low frequency switching applications. The problem is that they are generally not designed for RF use. They usually have very high input and output capacitances and a slow rise time. Well, not always. A company called Supertex (1235 Bordeaux Drive, Sunnyvale, CA 94089) has developed a proprietary process whereby they can reduce the capacitances and the rise time. Although they are not in the really high powered transistor business, they have a couple of 600 volt MOSFETs that offer exciting possibilities. These are the VN0360N1 and the VN0660N5. I have used the VN0360N1 in an amplifier for 80, 40, and 20 meters[1]. For improved performance on 20 meters, I used the VN0660N5. It is a somewhat lower powered device with a better rise time and lower capacitances.

One nice thing about 600 volt MOSFETs is that they are high impedance devices and are therefore suitable for use in tuned amplifiers. Another advantage is that they can be powered by the rectified and filtered 120 volt line without the need for a power transformer. My 20 meter amplifier uses a pair of VN0660N5s in a tuned push-pull circuit[2,3]. It was designed to run AC-DC style on the 120 volt power line. At 27 watts output, it runs at 45 percent efficiency.

Actually, my design was quite conservative. A pair of VN0660N5s could handle substantially more power. They are designed to dissipate 45 watts each at 25°C. The rated DC drain current is three-quarters of an amp. Another advantage is their price. At about $2.25 each, you could afford to use multiple transistors for high power.

Considering the length of time that transistors have been around, it is sad that progress in the RF power field has been so slow. Perhaps it is time for hams to take the lead again. So get out your calculator and soldering iron and go to work!

Antenna? What Antenna?

A stealth antenna farm for a small lot.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30, c/o Defendini
Salinas PR 00751-0030

Is an efficient antenna farm possible on a small lot? Yes, if you are willing to confine your operation to the seven ham bands from 40 through 10 meters, and are also willing to tweak an antenna tuner, which may be automatic or manually operated. With the new sunspot cycle just now beginning, these are the bands where the DX will be, where it will be easier to earn WAS, and where there will be many opportunities for casual rag-chewing.

But is it *really* a stealth installation that the neighbors won't notice? And how about restrictions against even TV antennas? How can this be possible?

Yes, it can be made "invisible" to neighbors, inspectors and casual passersby, even though it's right in view all the time. First I'll show you how to build it, then I'll show you some ways to completely fool anyone looking for an antenna. In fact, even another ham who did not read this article would never guess you had an efficient antenna farm while he was looking right at it. Now, that is about as stealthy as you can get—and still work the whole world.

The antenna farm

The antenna farm described here requires only three dipoles to cover all seven ham bands efficiently. All are slightly shorter than full-sized dipoles, but there are no traps—nothing fancy, just wire dipoles. They can be installed and fed separately, although this could take them out of the stealth category. They can also be installed horizontally and fed in parallel with a single feedline. I don't recommend either of these options; it is difficult to hide antennas which *look* like antennas even to a non-technical person.

I recommend installing the three dipoles as inverted vees using a common high support at the apex, which can be a mast, pole, tree, or anything else which is high enough. Also, I recommend feeding all three dipoles in parallel with a single feedline. Best of all, the recommended dipole lengths are all somewhat shorter than full half-waves and, while not resonant in any band, are easily and efficiently matched with any antenna tuner because all dipoles are close to the adjacent bands they are designed to cover.

"Your stealth installation can be made 'invisible' to neighbors, inspectors and casual passersby, even though it is right in view all the time."

What you will need

115 feet of antenna wire is sufficient to make all three dipoles, with plenty of wire left to make connections to the insulators. The center frequency of each dipole was carefully chosen so it will cover two or three adjacent bands, as listed in **Table 1.**

Feeders

I strongly recommend using 300- or 450-ohm open-wire feedline instead of coax. Because these dipoles are not resonant in any ham band covered there will be varying amounts of reactance at the center of each dipole. Feeding a reactive load will cause standing waves on the feedline, and power will be reflected.

This reflected power is subject to the same line losses as the forward power. Once it reflects back to the transmitter it is again reflected up the line to the antenna, where most of it is radiated and a small portion is reflected back once again to the transmitter. If coax feeders were used the I^2R losses would be much greater, and more power would be consumed in the coax on this back-and-forth trip. This situation occurs even with a 1:1 match at the antenna tuner, since the tuner is only tuning the rig to the line, not the line to the antenna itself. In other

Bands Covered	Dipole Overall Length	Length, Each Half
40 - 30 m	54 ft. 6 in.	27 ft. 3 in.
20 - 17 - 15 m	26 ft. 4 in.	13 ft. 2 in.
12 - 10 m	17 ft. 6 in.	8 ft. 9 in.

Table 1. Center frequency of each dipole was carefully chosen so it will cover two or three adjacent bands.

words, standing waves will occur on the line regardless of what type of antenna tuner is used.

Although similar standing waves and reflected power will occur on open wire feeders, the line loss is much less as the I^2R losses are so low as to be almost inconsequential. Remember that reflected power is always returned back to the antenna, *minus I^2R losses*, and re-radiated, *minus the power reflected* due to the line/antenna mismatch. This means that reflected power is not "lost" power—it is only lost when using a high loss feedline like coax, rather than the low loss ladder line.

Installation

Because every ham knows how to erect a dipole, either horizontally or as an inverted vee, and will do so if separately installed and fed dipoles are desired, I will describe only an easily-hidden installation with all dipoles erected as inverted vees and all using the same single support and fed in parallel with open-wire feeders. See **Fig. 1**, which shows the completed installation as viewed from directly above the central support.

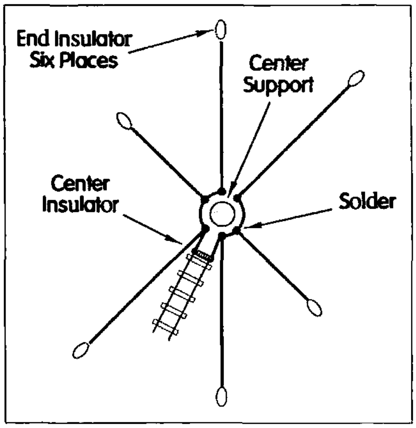

Fig. 1. Bird's-eye view of the triple-dipole antenna installation.

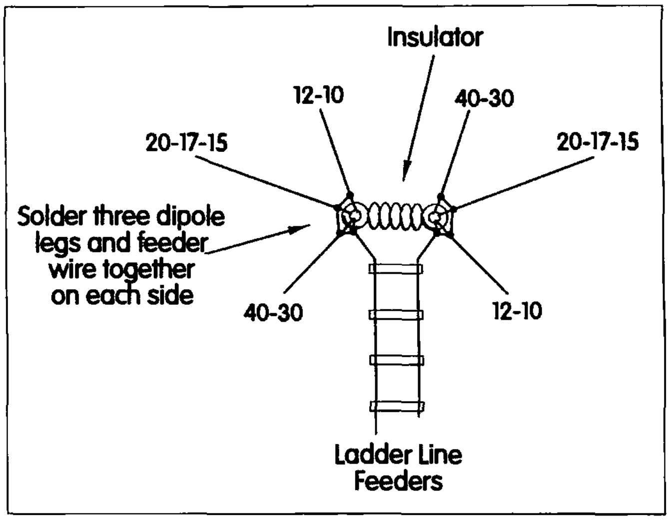

Fig. 2. Center insulator detail.

Seven insulators will be required: one at the common feed point, and one at each end of the three dipoles. Black braided Dacron® line about 3/16" in diameter should be used between each end insulator and its support point. The supports can be stakes driven into the ground, a hook on the side of a house or garage, a fence post, a tree—whatever is handy.

Although the 60° spacing shown in the bird's-eye view of the antenna installation is ideal, it is not a law of physics. Just space the halves of the antennas the best you can in the space available. The 60° spacing provides the least possible interaction between the dipole in use and the remaining two.

As the ends of the antennas are brought downward to tie off the ends to form inverted vees, do your best to have an included angle at the apex of each dipole of between 90° and 110°. Again, if space requires a somewhat greater or lesser apex angle, do the best you can.

Be certain the ends of the antenna wires are not less than six feet, and preferably somewhat higher, above ground. This keeps anyone from coming in contact with RF on the ends of the antenna.

Make sure the halves of each half-dipole are connected together at the feed-point insulator (see **Fig. 2**).

Tuning up

Your antenna tuner may or may not include a 4:1 unbalanced-to-balanced balun to match the unbalanced tuner output to the balanced feeders. If it does not, and all or most automatic

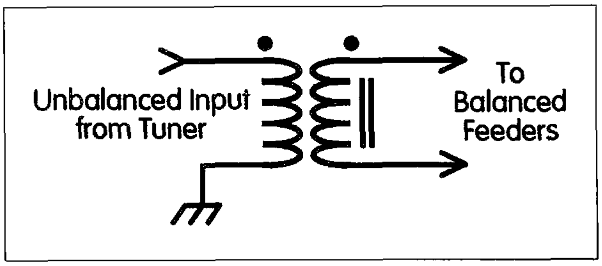

Fig. 3. Unbalanced-to-balanced 1:1 balun.

antenna tuners do not, you should build a balun to feed your antenna farm. Because the resistive component of the feed-point impedance on all bands is not too high, I suggest building an unbalanced-to-balanced 1:1 balun.

Caution: Be sure to use a core large enough for the level of RF power your transmitter produces. This is extremely important!

Fig. 3 illustrates the winding of a recommended 1:1 balun. It is bifilar-wound with enamel-covered copper wire of a size appropriate to your power output. For high power it is a good idea to cover the toroid core with a couple layers of glass or Teflon® tape before adding the winding.

Use a ferrite toroid, No. 43 mix. Calculate the number of turns necessary, using the formula below, with a required inductance of 0.075 mH (75 µH). The AL values differ for each size core and type of mix. Cores and a catalog sheet giving AL values and other information are available from Amidon Associates, Box 258867, Santa Ana CA 92799.

$$Turns = 10^3 \sqrt{\frac{mH}{AL}}$$

Another source of a complete line of toroids is Palomar Engineers, Box 455, Escondito CA 92025.

Hiding in plain sight

Depending upon many things, including the sensibilities of nearby neighbors and/or homeowners' association restrictions, you may find it necessary to camouflage your antenna farm without compromising the efficiency of its radiation. One of the best ways to camouflage the mast or pole supporting the feed point of your antennas is simply to place a birdhouse on top. Thus, your antenna mount has disappeared, while remaining in full view.

The antenna wires themselves escape notice, masquerading as guys stabilizing your lofty birdhouse. The end insulators, if they are white porcelain or glass, can be sprayed with black enamel. When the enamel is dry, rub a thin coat of silicone grease over the outer surface of each insulator to preclude any bridging of the insulators by rain. Dow Corning DC-3 or DC-4, or any product labeled "heat-sink compound" which does not contain white zinc oxide, are all good silicone greases.

Now that only *you* can see your antenna farm, the problem of bringing open-wire feeders from just below your birdhouse to the shack is more difficult. You might get away with explaining that the ladder line is actually a ladder for the use of birds with crippled wings. Don't take the easy way out, it won't be that difficult.

Parts List

- 115 feet of antenna wire
- 1 center insulator (feedpoint)
- 6 end insulators
- Black braided Dacron® rope, 3/16" diameter
- 1 unbalanced to balanced 1:1 balun (see text)

Bring the ladder line vertically down the birdhouse pole, stapling it occasionally through the insulation, or use hot glue. Paint the line the same color as the pole, at least as high as you can reach standing on a kitchen chair. Adults will never notice it, because few adults pay any attention to anything much above eye level.

The ladder line now will probably have to be routed through a length of PVC pipe from the pole to the shack wall, but it's not a good idea to have your feeders close to the ground. The pipe should be more than head-height above the ground and be painted to match the general area, perhaps even mottled to break up its lines.

The pipe containing the feeders, if supported by a few uprights which have vines planted around them, will turn this part of your feedline into a growing frame for grapes, flowering vines, pole beans etc. It might also be a good idea to temporarily wind some plastic vines around the uprights and feeder pipe as immediate camouflage.

Plastic vines can also be wound through ladder line and the feeders taken directly from the pole into a second-floor shack, though this might invite comment.

If you want to find out just how stealthy you have made your antenna farm, invite a ham who has not read this article to your home and "cry on his shoulder" a bit about the antenna restrictions and not being able to put up a decent antenna and see what suggestions he has to offer. Take him into the yard and ask for ideas. He probably will suggest a vertical attached to the side of the birdhouse pole. Then take him into the shack, turn the rig on, and let him be amazed at what he can hear as you have a QSO or two. Then, just to be friendly, tell him who told you how to do it.

Because each stealth antenna farm will be different, use your imagination. I've offered a few hints here, but you'll probably have even better ideas. And maybe you'll write about 'em.

Hentenna Footnotes

Using an EZNEC model to build a sample.

Thomas M. Hart AD1B
54 Hermaine Ave.
Dedham MA 02026

I like antennas and antenna articles. Recently, I have discovered the joys of modeling antenna designs on the computer with the EZNEC program (available from Roy Lewallen W7EL, P.O. Box 6658, Beaverton OR 97007; phone 503-646-2885, FAX 503-671-9046, E-mail w7el@teleport.com), and only building samples if the results look promising.

73 printed an interesting article by KAØDAQ in the April 1996 issue, titled "The Hentenna." For the first time, I found a complete set of formulas in print that helped in the design work.

In order to learn more about the Hentenna, I reviewed my own antenna references, ran a model on EZNEC, and built a sample for the FM broadcast band.

Hentenna Computations

MHz	1/2 WL	1/6 WL	Total Wire	Feed Point	
146.0	3.4	1.1	11.5	0.8	Feet
	41.3	13.8	137.7	9.6	Inches
90.9	5.5	1.8	18.4	1.3	Feet
	66.3	22.1	221.1	15.5	Inches
50.1	10.0	3.3	33.4	2.3	Feet
	120.4	40.1	401.2	28.1	Inches
29.5	17.0	5.7	56.8	4.0	Feet
	204.4	68.1	681.4	47.8	Inches
28.4	17.7	5.9	59.0	4.1	Feet
	212.3	70.8	707.7	49.6	Inches
21.3	23.6	7.9	78.6	5.5	Feet
	283.1	94.4	943.7	66.1	Inches
14.2	35.4	11.8	118.0	8.3	Feet
	424.6	141.5	1,415.5	99.2	Inches
7.2	69.8	23.3	232.6	16.3	Feet
	837.5	279.2	2,791.7	195.7	Inches
3.6	139.6	46.5	465.3	32.6	Feet
	1,675.0	558.3	5,583.3	391.4	Inches
1.8	276.1	92.0	920.3	64.5	Feet
	3,313.2	1,104.4	11,044.0	774.1	Inches

Evolution of the Hentenna

A book, now long out of print, *Radio Amateur's VHF Manual* (©1972, ARRL), describes the "Skeleton" or "Slot" antenna based on designs by B. Sykes G2HCG. The illustration shows the process that changed two horizontal half-wave dipoles into the final rectangular Hentenna design. The antenna was popular at the time of publication and a commercial model was marketed by J-Beams Ltd. The antenna is characterized as horizontally polarized, with vertical sections that act as wide-spaced transmission lines.

Etymology of "Hentenna"

"Hen" comes from the Japanese word for "interesting" or "unusual." In an article titled "Let's Make the 'Hentenna'" (*QST*, February 1982), Koji Sugihara JJ1UMS stated that the design was very popular on 6 meters (about 10% of the installed base). Horizontally polarized, the antenna was very forgiving about dimensions; a 5-10% variance from design specifications had little effect. The antenna could be fed with either 50 or 72 ohm coax, directly or with a balun. The feed point was a Y-shaped wire that was moved up and down to determine best match before final attachment.

Dimensions

Table 1 shows the lengths of the sides, as well as feed point location, based on the experiments by KAØDAQ. Clearly, the antenna is best suited to 10 meters and above. It would be possible to try

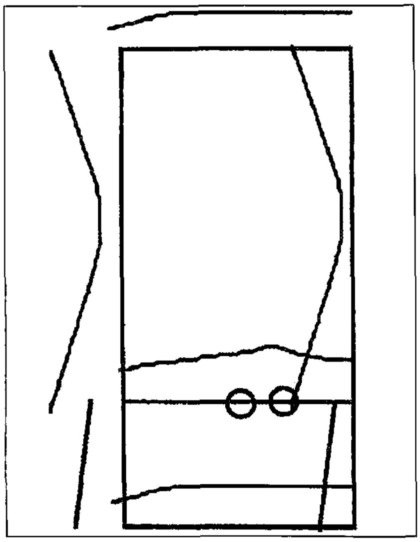

Fig. 1. Currents on the antenna during operation.

one on 15 and 20 meters, but the structure starts growing large here. Hentennas on 40 through 160 meters are well out of the ordinary person's reach. I had no problem constructing and using a sample on 90.9 MHz, the local National Public Radio Station, WBUR in Boston. It works!

The 10 meter report

Bill Orr W6SAI included an illustration and discussion of the Hentenna in his monthly column in *Ham Radio* magazine, May 1989. He discussed a letter from JE1DEN which contained information on using the design on the 10 meter band in Japan.

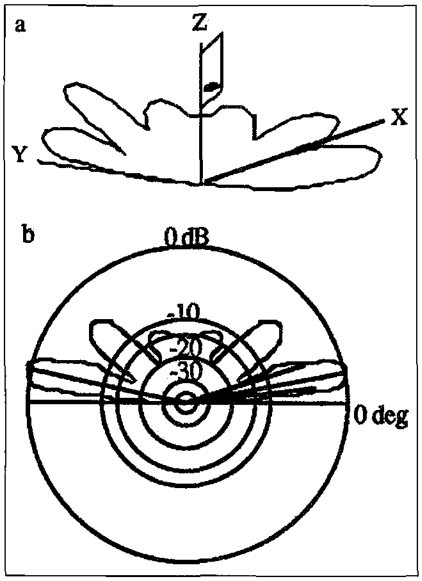

Fig. 2. EZNEC elevation plot, perpendicular to antenna plane.

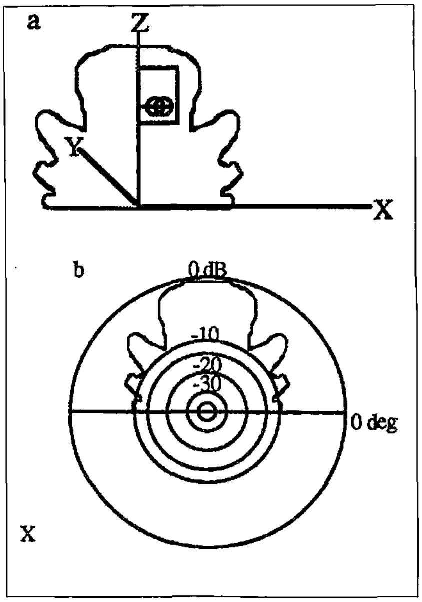

Fig. 3. EZNEC elevation plot in the plane of the Hentenna.

EZNEC report

Fig. 1 shows the currents on the antenna during operation. Next, elevation plots were prepared to show that the strongest radiation is perpendicular to the plane of the antenna. The takeoff angle is 11 degrees in the sample, favoring distance work. The elevation pattern in the plane of the antenna is, as expected, attenuated and provides a high takeoff angle of 81 degrees.

> ***"The Hentenna is a very interesting, often overlooked, design that can be used on HF and VHF installations."***

Switching to the azimuth plot, we find a very pronounced figure-eight pattern. This has been reported in the literature and supports the elevation plot data. The Hentenna is strongly directional and can be used with parasitic elements.

Polarity considerations

The Hentenna is horizontally polarized. Does this matter? The answer is "maybe." If you operate on the HF bands and depend on the ionosphere, the answer is probably an unqualified "no." Refer to the *ARRL Antenna Book* (©1994, ARRL). Here, we find that in the range from 3 to 30 MHz, skywave transmissions change their polarizations.

Antennas at either end of the connection don't need to have the same polarization.

For short-path communications, VHF FM work for example, polarization may be quite important. Cross polarization can result in 20 dB losses in cases where different methods are in use at the transmitter and receiver.

Conclusions

The Hentenna is a very interesting, often overlooked, design that can be used on HF and VHF installations. The literature contains references to installations on 10, 6 and 2 meters. The structure is simple and rugged when properly assembled. The horizontal polarization may be a concern in VHF use, especially on repeater work. This design is one that should not be overlooked when planning additions to the antenna farm, or in my case, antenna garden (I have too little space to build a farm!).

NEVER SAY DIE

Continued from page 69

shots and she showed an immediate and dramatic improvement.

Though the medical literature has thousands of similar stories and doctors are quite familiar with this response, which they call the placebo effect, what they haven't done is find out how and why it works so they can then harness its power to help cure people.

I've seen medical reports saying that the placebo effect can work in up to 80% of all illnesses. But no matter the percentage, here is a way which could help cure a wide range of illnesses that the medical industry is refusing to research and develop. Why? Simple, there isn't any money in selling placebo based cures.

Back when I was a professional psychotherapist I found that every illness had a psychological trigger. By de-activating this trigger the illness would go away. And the de-activating procedure was fairly simple. At the time the medical industry ridiculed the whole idea. In the intervening years doctors have come to admit the importance of psychological components in illnesses, but I defy you to find one doctor anywhere in the world who is making use of this knowledge.

Twenty years ago I suggested in an editorial that one excellent application for personal computers would be to use them in doctors' offices and hospitals to uncover the psychological trigger for illnesses. The procedure is so simple that even a desktop computer, operated by the patient, could be programmed to find these triggers for doctors. There would, I suspect, be a pretty good market for such a computerized diagnosis system.

Then I'd have to write a handbook for doctors on how to de-activate the psychological triggers, since I suspect I'm one of the few people left who know how to do this.

What is Truth?

If I say that I believe that extraterrestrials are and have been among us for thousands of years, is your reaction that poor old Wayne is off his rocker? Or do you agree? And if you think I'm off my rocker, are you at least willing to look at the evidence that convinced me?

Okay, how about telepathy, auras, spoonbending, psychokinesis? These, too, are subjects that are off-limits for scientific investigation. Not only won't they be funded, ridicule and humiliation await the brave and inquiring.

Now let me be specific. Let's take Uri Geller, for instance. Was he just a stage magician or was he really a psychic? Unless you've done some serious research you probably don't know that Geller performed for scientists under the most carefully controlled laboratory conditions. He has been videotaped while being carefully watched by both professional conjurers and scientists, using no materials provided by him or that he even had prior access to, remotely affecting scientific instruments, even producing objects out of thin air, and locating hidden objects with no errors.

Geller submitted to endless exhaustively controlled experiments at several colleges. For instance, a dozen aluminum film cans would be put on a table. Some had water in

Continued on page 78

NEVER SAY DIE
Continued from page 77

them, some steel balls, and some sugar cubes. Geller did not touch the cans, but was able to identify the contents in all 12 correctly. The odds were over a million to one. Geller was able to make Geiger counters click, and other scientific instruments give weird readings.

Yes, I agree, I'm off my rocker. But that's because I haven't time to sit around rocking when I prefer rocking the boat. I've a nice rocker—a gift from an appreciative college president for my consulting work for him and the deans. But how can I spend time sitting around rocking in my old age when I feel I should be writing about the anomalies that the scientific establishment is not just ignoring, but is actively trying to prevent being investigated?

Like, did you know that plants somehow communicate via UV? The research results are amazing, but the odds are that you've never seen them published. Ditto the work of Rife, Naessens, Reich, Ott, Backster, Tesla, Rawles & Davis, and a bunch of other martyred scientific pioneers. Books about many of 'em are on my $5 list of books you're crazy if you don't read. On trips, my suitcases are more loaded down with books I'm reading than clothes. Or are you like the average American schoolteacher, who reads one book a year (usually fiction)? I read two or three non-fiction books a week. Sure, some are a waste of time, despite high recommendations from readers, but others go from good to superb, with a few making it when I update my book list.

Perhaps you can understand why I see so many pioneering opportunities for anyone with the guts to oppose the scientific mainstream.

Day Care

The election of state senator Jeanne Shaheen to governor of New Hampshire got me to thinking. I worked with Jeanne on the Educational Subcommittee of the New Hampshire Economic Development Commission, so I got to know her pretty well.

Jeanne had a fixation on the need for New Hampshire schools to be legislatively forced to include kindergarten for five-year-olds. I agree that youngsters should be given every opportunity to learn during their early years, but I'm just not a fan of having the government force everyone to do what a legislature has decided is best.

For that matter, I am most critical of the whole "day care" concept. I grant that there may be some day care centers that provide children with the opportunities to learn a wide variety of things. However, I suspect that most of them operate like the ones I've seen where the children are started early being taught regimentation, and their exposure to new ideas and experiences are limited to what Sesame Street and Mr. Rogers provide.

Here is a time, when kids are two to five years old, when around 90% or so of their lifetime character is being formed. This is a time when they should be provided with the tools and encouragement to learn and experiment.

This is the best time to teach children several languages. This is when they should be helped to experiment with drawing, clay, painting, playing musical instruments, exploring nature, and be taught any skills that may interest them—like juggling, gymnastics, playing games, learning to read, building their vocabularies, skating, skiing, swimming, and so on. This is the time when individual interests should be encouraged rather than group conformity. Between genes and early nurture, everyone is different. But it takes a teacher/salesman to enhance the positives and bring out the uniqueness of each child without stifling their curiosity and enthusiasm.

Early animal trainers used punishment as their main method of teaching. Then it was found that far faster and better results were obtained using kindness and reason. This concept has not yet caught on with many teachers and parents. It does require that the teacher be able to outthink the animal (or child) and devise a way to convince the animal that it wants to do what the teacher is encouraging. This results in a happy, cooperative animal. And child.

Perhaps if we change the name of day care centers to early learning centers that would help. Ditto children's garden, a.k.a. kindergarten, which should merely be an extension of the early educational and development process. Given the opportunity, encouragement and the tools, many kids will be able to enter the first grade already accomplished in reading, writing, dancing, acrobatics, playing one or more instruments, able to speak several languages accent-free, be good swimmers, and have already developed several other skills. To do other than this is, to some degree, putting children in straightjackets mentally and developmentally. And remember, that once the window of opportunity for children to learn certain skills has passed, it is a lost opportunity. For instance, never again will children be able to learn many languages as easily. I suspect that musical and dancing skills are the same.

Portable Classrooms

I've proposed that state school systems encourage (and fund) their schools to build portable laboratories into trailers so the facility can be shared by a number of schools. This would make it so that chemistry, woodworking, metalworking, electronics, computer, photography, video production, audio recording, music appreciation, cooking, and other such expensive equipment systems could be shared by several schools, thus

providing a greater learning experience at a lower cost per student.

I'll bet a good deal of corporate funding could be made available to help build these mobile labs.

For the younger kids this would make a way to bring exploratoriums to them, to provide them access to more expensive musical instruments such as pianos, electronic instruments, and recording facilities.

But how can we bring about the needed change? If you do nothing, nothing will change. If you start pushing for change most people will fight and ridicule you.

Are you a leader or a follower? Our present day care and school system inculcates us early on to be followers. Don't rock the boat. The nail that sticks out gets hammered down. If it ain't broke, don't fix it. Ya-ta-ta, ya-ta-ta. Maybe, if you'll help fix our educational system, we'll have more leaders and fewer followers. Boy, will that screw things up! Ha!

Arrested!

Greg Godsey KF4BDY, a 16-year-old ham from Paulette Court, Kentucky, was arrested while demonstrating the severe weather Skywarn system to a group of people. He was charged with the possession of a police scanner, impersonating a public servant and disorderly conduct. The police confiscated his Radio Shack HTX-202 2m HT.

The HT was later returned when the police found that it was a legitimate piece of ham radio equipment which could not be used to eavesdrop on their communications. But for some reason they'd taken it apart, so it had to be sent back to Radio Shack to be serviced.

And what about the impersonating a public servant deal? Well, Greg had an Amateur Radio Emergency Service ID. But the police and the court refused to accept that ID, so as far as they are concerned a credentialed Amateur Radio Service volunteer *is* impersonating a public servant and that constitutes an act of disorderly conduct.

Thanks Chicago FM Club *Squelch Tale* for that gem. Remember, the police are your friends and judges are ex-lawyers. However, if you have an ARES card, it can get you arrested. You go to jail and the court collects the $200.

Nondisclosure Agreement

How'd you like to make a few million bucks? Well, I have an idea for a simple electronic product that'll be easy to make and should sell by the carloads. It could almost revolutionize an industry. We need a manufacturer and a hundred or so sales and service reps.

Now, before I disclose the details of my idea I want it understood that the reading of this constitutes a legal binding contract between you and Wayne Green that you will (a) not disclose this idea to anyone else, and (b) if you decide to get involved in the manufacture or marketing of the products described that you will reserve a minimum of 2% of gross sales as a royalty for said Wayne Green.

That out of the way, here's the sneaky plan. The germ for this idea was spawned back around 1978 when Sherry and I had lunch with Ed Juge W5TOO at a Mexican restaurant in Ft. Worth.

I'd known Ed for many years. He'd advertised his Juge Electronics store in my magazine and we'd gotten to be friends. Cut to 1975 when I was taking the first issue of my brand-new *Byte* magazine around to drum up advertising. My first stop was with Sphere Computers in Salt Lake City. Then down to Albuquerque to visit Ed Roberts at MITS. From there I stopped at Ft. Worth and dropped off some copies of the magazine with Ed Juge, explaining that I felt that the personal computer field was going to eventually be a huge new business that would eventually be larger than the automobile industry.

Ed bought an Altair 8800 from MITS (the first microcomputer) and was hooked. The ARRL's so-called "incentive licensing" proposal had so gutted the ham business that Ed was fed up and was looking for something new to do. It was at this time that Radio Shack decided to get into the personal computer business. That's a whole story in itself—one that needs to be told. Anyway, since Ed was right there in Ft. Worth, and already had some experience with microcomputers, he joined Radio Shack to help them market their TRS-80 computer. It was a great little computer and, with the help of several thousand stores to sell it, it quickly grabbed the lion's share of the market.

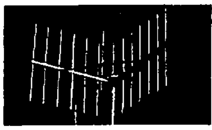
Getting back to that Mexican lunch. This restaurant had a little flag on each table for us to raise when we were ready for more hot *sopaipillas*. Great idea. (Then there was a restaurant in Manchester (NH) that had a light you could switch on to call the waiter. Also a good idea.)

You have the same problems I have. You have to wait for a menu. Then you have to wait for the waiter to notice you're ready to order. When you run short of water or something, getting the attention of the waiter is difficult. The worst is getting the check. At that time the waiter totally disappears as your frustration mounts. It helps you understand why these people are called waiters. They make you wait. And wait. It's no wonder fast food has gotten so popular.

Okay, Gadgeteers

What we need is a beeper system, with one unit attached to your waiter to show the number of the table wanting service, and a unit on your table to call the waiter. Whether it is infra-red or microwave is up to you. It wants to be simple, as inexpensive as possible, legal, fairly foolproof, and not require much service. If there is such a product I haven't seen it at any electronic shows, nor have I heard of any restaurants using one.

Continued on page 81



The Quest for the Ideal QTH

A New Jersey paradise for this ham.

Bert Simon K2FZ
2110 NW 45th Avenue
Coconut Creek FL 33066

At one time my goal was to be the "buzzard on the highest perch." I sought the ideal radio location—and eventually found it, lived on it, and enjoyed every moment of being there.

I laid claim to having the highest permanent resident ham location in New Jersey. The highest point in New Jersey is at an area called High Point, and if my memory serves me right it was in excess of 1,800 feet above sea level. The location I eventually settled for was at 1,240 feet above sea level and was approximately 300 feet above average terrain. A 60-foot tower would put my beam antennas more than 1,300 feet above sea level. Although I worked other stations in New Jersey that were higher, they were Field Day setups—with High Point, of course, being one of the favorites.

It doesn't take a rocket scientist to realize that when it comes to strong ground wave signals, the higher the ground and the clearer the shot means the stronger the signal. And so the search went on to find that elusive higher ground which would lead to a ham paradise, the ideal radio location.

There were other factors to consider. Was the QTH readily accessible without investing thousands of dollars to build a road? Was electrical power available or would I be required to spend additional kilobucks to put in power lines and/or an independent generator? Could I get in and out when the snowstorms arrived? Was it far enough away from the very high voltage power lines which could radiate enough 60-cycle harmonics to bounce signals off Saturn? Were there any restrictions (or possibility of) involving townships or neighbors who might not appreciate the wonderments of an antenna farm? At one time I was approached by some township officials who voiced the opinion that "They weren't sure whether they wanted radio towers in their township." I informed them that I had permission from the FCC and the FAA to construct the towers and that was all I needed, but that was then and this is now. I would recommend further study and perhaps some legal advice. The other factor, carrying perhaps the most significance, was the ability to convince a spouse that "this is the place to live."

"The band was dead with respect to skip, but on many occasions ZSs would break in just to let me know that I was the only stateside station being heard."

Choosing the site

I started on my ham crusade by obtaining geodetic and survey maps for the entire state, and then spent a great deal of time studying them and visiting many proposed locations. Was the subject QTH far enough from heavily traveled highways so as not to be subject to automobile ignition noise? Finding proposed locations was relatively easy but finding the ones that had land available and accessible was another problem. I recall many disappointments.

I made my choice and I'm happy to report that between 1959 and 1978 I had the greatest ham location that one could ask for—and one every ham should experience. There were certainly many higher locations available throughout the United States but were they within radio metropolitan range of an area such as New York City? Mine was, and that added so much joy to the ground-wave contacts, which had an approximate radius of 200 airline miles. The QTH I had chosen was about 40 miles northwest of Central Park, New York City; for those familiar with New Jersey, it was in Jefferson Township at the intersection of Morris, Passaic and Sussex counties. It was on the northwest ridge bordering the Oak Ridge Reservoir, which supplied water to the city of Newark. My five acres of property bordered on thousands of acres belonging to the City of Newark Watershed.

There were no restrictions on antennas. I could put up anything I wanted. I settled on a seven-element triband beam for 20 through 10 meters and antennas ranging from 11 elements on 6 to 20 elements on 2, not to mention full-size dipoles on 80 and 40 meters. Life was good!

Another desirable factor in a great QTH was to have a low-noise location, radio-wise. This was borne out by the constant "whistlers" (part of an ionosphere phenomenon) I would detect in the 20 to 30 MHz range. I would pick them up slightly higher than 30 MHz and observe on a panalyzer as they waddled down in frequency (it really looked like waddling) until they diminished somewhere about 20 MHz after sort of "FMing" themselves to death.

Some highlights

I can recall one winter snowstorm when all travel came to a halt. I heard some QRN on the 15 meter band that sounded like noise being generated from some type of an electrical appliance. I left the door of the radio shack open, stepped out into the snowbound road and looked down into the valley where I could see a section of Route 23 in Stockholm, New Jersey, which was approximately three miles away. I heard the noise in the receiver and simultaneously spotted a puff of smoke coming from a snowplow. This was repeated several times until I realized that the snowplow was the source of the noise and since it was diesel-operated, what I was hearing was not ignition noise, it was alternator noise—three miles away. Early morning differences in noise background could be detected depending upon the pointing of the antenna with respect to the sun. I can recall observing some weird noise which sounded like a mishmash of several signals when the antenna was pointed in a certain direction, which happened to be towards the abandoned Edison mines, about eight miles away. I never did find out what caused that interference; the signals weren't that strong and besides, I couldn't find anyone else who could hear it to confirm its presence.

"I could put up anything I wanted—life was good!"

I remember, with delight, many evening ground-wave QSOs with New York City/Long Island hams which put my antenna in the direction of South Africa. The band was dead with respect to skip, but on many occasions ZSs would break in just to let me know that I was the only stateside station being heard. I guess having a Henry 2K4 and six elements on 15 didn't hurt. On many occasions I would work 15 meter ground-wave stations at a distance of approximately 200 miles and the ham on the other end would excuse himself so that he could work "other short skip stations."

So why did I give up this ham paradise? It was just time to do something else. I sold all my possessions, bought a sailboat and lived aboard while spending the next 15 years in the sunny Caribbean between Puerto Rico and the Virgin Islands.

Within the past year I had occasion to be within five miles of my old QTH and couldn't resist visiting. My old ham shack was now in use as a garage—to coin a cliché, you can't go home again. 73

NEVER SAY DIE

Continued from page 79

Step one is to design the transmitting and receiving units. Keep 'em simple. Sure, I'll be glad to publish your solution, if it looks promising. And yes, any manufacturers who decide to use it should pony up a 2% on gross sales royalty to you too.

Once something like this starts to catch on, every restaurant will have to invest in a system.

My preference would be to use infrared—like your TV remote control units. With a little power a table unit can cover a large area. A booster can be installed if needed to cover the kitchen.

Hey, do Sherry and I get some free meals out of this?

Selling Music

For that matter, you should be able to make a nice living selling audio systems to restaurants, complete with CD players and a set of appropriate ethnic music CDs. Mexican music for Mexican restaurants; Italian, Chinese, and so on. The sales and service in providing good music for a few hundred restaurants should keep you out of trouble. The next thing you know you'll be on your way to Mexico, portable digital recorder in hand. Or Greece. Or Japan. Oh, and don't forget that 2% for Wayne. On gross sales. 73

LETTERS

Continued from page 62

While waiting for one of their security people to drive me back to my apartment, the Colombian Navy captain and I were alone and he told me about an encounter one of their frigates had with a UFO one night while on patrol along the Colombian coast. Recently I had a Colombian AF colonel in one of my classes at DLIELC, so I asked him if he had ever been given a briefing in which he was told that we have been having extraterrestrial visitors. Looking at me directly, he responded, "Yes." Most Colombian AF officers apparently have not had such a briefing, only those working at the highest levels.

Continued on page 82

LETTERS

Continued from page 81

A couple of years ago I participated in a MUFON investigation of a family's encounter with a UFO that had hovered over their farmhouse near San Antonio, frightening them badly. There were three witnesses: a mother and two of her children. The 13-year-old daughter stayed outside looking at the craft the longest and experienced some physical symptoms (sunburn, fever, etc.). All felt heat and came down with colds shortly afterwards. The younger son will not go outside the house alone anymore and the daughter couldn't sleep at night for long afterwards. Other strange things occurred that evening and there is some suspicion that one or more family members were abducted. The UFO phenomenon is quite bizarre and I'm also puzzled, amused and frustrated by the strange human response. Why aren't more people eager to find answers to the questions being raised?

That's simple, Cliff: We believe what the government tells us. The government wouldn't lie to us. But then there are a few troublemakers like you and me. I personally know the government is still lying about Amelia Earhart, even after 60 years.

A few years ago I was called by a farmer to look at some crop circles in Francestown, NH. I talked with the woman who lived next to the farm and she told about a UFO that had hovered over her house for several minutes a few nights previously, scaring the heck out of her and her children. When her husband got back he ridiculed her and the kids. The next day he apologized when he reported that the staff at the Crotched Mountain Children's Rehabilitation Center a few miles away reported the same silent bright light hovering over their buildings that same evening, and then zooming away at an incredible clip.

Then there's a chap with the highest security clearance who is a consultant to President Clinton who called me a few days ago. He's had several contactee experiences himself and his son, in Annapolis, reports that they are teaching the upper class students that the ETs are already here. I do wish someone would teach these critters to talk instead of always using telepathy, and lend them some HTs so we could let them hear what a pileup sounds like... Wayne.

John Peters K1ER/KH6. You asked for a report on Dayton. Well, in brief, it stank. The WX used to be wet and cold, which was easy to handle with a waterproof jacket. This year the stupidity of the shift to May was demonstrated by pouring rain for several days before the HamVention, making it possible for the humidity to be unbearable on Friday and Saturday when the temperature was unbearably *hot*. The flea market seemed to be about 50% full, with many of the spaces purchased by people looking for a close-in parking space. Nothing in the flea market space but a parked vehicle. The flea market was *not* taken over by computers, it was taken over by completely useless junk—old lab equipment (junked by hospitals), old telephone equipment junked by some telephone company. Much less ham gear or computers than before. The tent area, normally known for the two or three inches of water running over your feet, was hot and humid, and contained basically the stuff that didn't sell at the local Radio Shack. The flea market was a bust. The inside displays were the same gang as usual. It would be hard to tell one year from another, except that it was *hot*.

You should have had your own forum in competition with those scheduled. Best example was the DX forum. Scheduled to start first thing in the morning with a set schedule of topics. So far so good. The first event was Bill K from the DXCC desk who was scheduled to talk for 30 minutes or so. He took five to say the card checking backlog is gone and all's well with the world. The DXAC chair then announced that there was really nothing controversial going on with the DXAC (probably the most blatant statement before the presidential lies started) and sat down. With no questions or arguments, and since the forum was then approximately 50 minutes ahead of schedule (the later speakers had not arrived), they

just adjourned! The speakers arrived to find an empty hall. The DX Dinner was not improved over prior years. But anyone who doesn't know that deserves bad food, bad acoustics and bad service. I was supposed to help open a hospitality suite 30 minutes before the scheduled end of the DX banquet, and at that appointed time the banquet food had not yet been served. I could discuss other events, but why bother? The only reliable high spot was the bar on the top floor above the DX dinner, which was as good as ever in spite of the hotel sale to the Holiday Inn chain and name change. Same friendly staff every year.

They should move the event back to April when the weather can at least be compensated for with clothing. Don't ask why any sane person would go from Hawaii to Ohio in May! I figured it was close enough to the International DX Convention in Visalia, so why not? Now I know why not. At least the museum at Wright Pat had a few new exhibits, and I saw a few hams I knew. I may go next year just for the Collins Collectors meeting and skip the rest. I figure Slick Willie is going to get us into a war in Korea again by continuing to weaken the military, and the troops will need phone patches home. I need more things for the MARS frequencies before it starts.

I had expected to hear you at Dayton; sorry you weren't there. If you want to lose weight, the food and heat will sweat off a few pounds. I'm not sure any magic is involved in living long. Just stay away from doctors and hospitals (that's where the pathogenic organisms are found!) and have DNA from great-great-grandma who lived to 104, grandparents to 98, and eat less.

Hmm, by publishing your letter I've probably guaranteed that I won't get invited to speak next year. C'est la vie. But, how about some positive letters? Some of you must have had a really good time! Speak up. However, with that humidity and temperature I can understand why the speakers didn't want to talk very long. The thought of around 50,000 pounds of ham fat in a closed steam room is challenging... Wayne.

UPDATES

Resistance is futile?

If you look at **Fig. 1** of "Enhanced Automatic Voltage Controller" on page 43 of the January issue you'll see that we neglected to label one of the resistors. The resistor right next to R12 is R11.

Frank-ly speaking...

In Frank Brumbaugh's "Audio Filter Alignment Generator" from the December issue (page 42) there was a typo in **Fig. 1**. The **3** was accidentally labeled **9**.

In addition, Frank sent us a memo saying that there have been some problems with the 74LS90 chips: If the output from pin 11 of U2 does not divide by 5, you should take the output from pin 8 instead. 73

Bruce Muscolino W6TOY/3. Dayton Bombed? I think not! Seemed to me the crowd was pretty much on a par with last year. True, nothing like five years ago, but still a fun and worthwhile trip, and no rain!

One group of hams actually had a bumper year this year at Dayton—the QRPers. The story began in 1995. Traditionally, like many other special interest groups, the QRPers hold a separate meeting. Our meeting is sponsored by the QRP Amateur Radio Club International (QRP-ARCI) and is complete with a hospitality suite, vendors, radios to operate, and a place to sit and tell war stories to friends. QRP enthusiasts from around the world attend each year, with a large group coming from the G-QRP club.

QRP is thought by many to be the fastest growing segment of amateur radio today. Certainly there has been tremendous interest in low power operation as evidenced by regional and national club memberships in the thousands and an active Internet list with nearly 2,000 members. However, the "dumbing down" of ham radio over the last 25 years has led to many hams who have less than a solid working knowledge of the technology underlying their hobby.

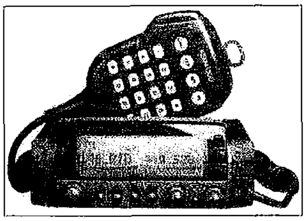
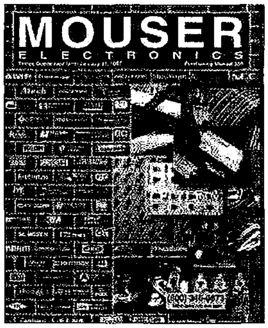
New Products



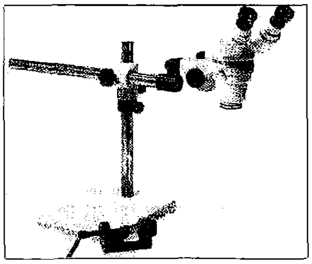
New, Cool, and Blue

Kenwood's new TM-V7A dual-band mobile is a sleek, slick baby with tons of features, including a large display and 280 memory channels. The front panel can be easily mounted anywhere in your vehicle and the optional voice synthesizer is handy as all get out for mobile operation. Transceiver guidance function shows you, step by step, how to perform some functions without the need for the manual. Visual Scan function allows you to look at band activity graphically, and there are more than a dozen other features. Check it out at your Kenwood dealer.



New Mouser Catalog

The latest electronics components catalog from Mouser is now available—332 pages of more than 68,000 products from today's leading electronics manufacturers, including new additions from Switchcraft, Cornell Dubilier, SGS Thomson, Xicon, and more. You'll find complete specification drawings, guaranteed prices, and same-day shipping on all in-stock products. Buyers, engineers, and just plain catalog dreamers will want to latch on to this one. For a free copy, call (800) 992-9943; E-mail catalog@mouser.com; web site http://www.mouser.com; FAX (817) 483-0931.

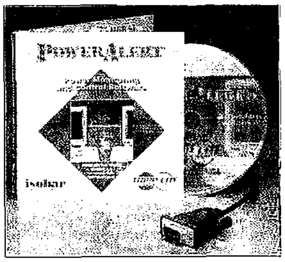


Booming Stereo

WASSCO introduces the new Stereoscopic Microscope on boomstand from Clearview Instruments. The boomstand is available with or without a clamp base; the arm extends to 16 inches around the base, and, with a 360° swing arc, it will go virtually anywhere around your work surface. The clamp base adds even more portability and flexibility.

The binocular head is at a comfortable 45° angle, so you can peer for long periods of time at those really delicate connections, and the image is unreversed, for uncomplicated manipulation of the item in view. Prisms maximize light transmission, and the parafocal zoom system keeps the image in constant focus—and it comes with a lifetime guarantee!

For a complete listing of Clearview Microscopes and advanced optical instruments, call 1-800-4WASSCO or visit the web site at www.wassco.com.



Cross-Platform Compatible

Tripp Lite announces Version 9.0 of PowerAlert Plus UPS power management software, which is the only software that has the capability to work with software sold by American Power Conversion (APC).

Version 9.0 will perform all functions of APC's PowerChute power monitoring software, including full system shutdown, system test and power failure simulation. Since Version 9.0 is fully compatible with all APC software features, users of current APC UPS systems are no longer dependent on using only APC products. Users can now take full advantage of Tripp Lite UPS systems without reconfiguring their server installations.

Version 9.0 is a no-cost option with Tripp Lite SmartPro UPS systems. It is also available separately for $89. For more information, contact Tripp Lite Customer Support at (312) 755-5401; FAX (312) 644-6505; E-mail: info%tripplite@mcimail.com; web site: http://tripplite.com.

Kepro Named Distributor

Kepro Circuit Systems, Inc., a St. Louis-based worldwide supplier of etched circuit board equipment and supplies, has been named one of the US distributors of KPR Liquid Photoresist products by Fry Metals. KPR is a high resolution liquid photoresist for fine line detailing of etched circuit boards. Designed specifically for undiluted use on copper, copper alloys, and anodized aluminum plates, KPR products are negative-acting photoresists for dip coating, flow coating, spray coating, and roller coating applications. Coatings can be air-dried or infrared oven-dried. Exposure is done with carbon-arc lamps, mercury-vapor lamps, pulsed-xenon lamps, and unfiltered ultraviolet fluorescent tubes. KPR products require specific developing solutions designed to be compatible with each photoresist. Since 1954 Kepro has provided state-of-the-art equipment and supplies for prototyping and short-run production of etched circuit boards, and Kepro products are available virtually anywhere in the world. For more information, contact Kepro Circuit Systems, Inc.; 630 Axminster Drive, Fenton MO 63026-2992. E-mail: kepro @worldnet.att.com, or call (800) 325-3878; Fax (314) 343-0668.

The Future 1 Is Now

It's smaller than a notebook, but so advanced it's set to revolutionize the telecommunications industry. The Future 1 Planar Satellite Antenna from *galaxis* can receive over 100 TV and radio stations, but its flat, compact design means it's much less obtrusive than traditional dishes. The totally weatherproof design ensures continual maximum reception for home and mobile installations, like RVs and boats. The Future 1 can also receive both analog and digital satellite stations, and it's just the first in a whole family of new antenna products from *galaxis* USA Ltd. See your antenna dealer.

New Free Catalog

MCM Electronics, for 20 years a leader in the distribution of consumer electronic repair parts and accessories, has released their new catalog. More than 6,000 items, including project accessories, semiconductors, connectors, test equipment, hundreds of original and generic TV/VCR parts are at your fingertips. New sections are included; computer software, gaming and amusement, printer parts among them.

Franchised lines offered for the first time in this catalog include Lexmark, ECG/Philips, and Sencore. Name brand offerings have been expanded to include Brax, Sovtek, and more.

Approved, in-stock orders received by 5 p.m. will be shipped the same day. For a free copy of this new catalog, write to MCM Electronics at 650 Congress Park Dr., Centerville OH 45459-4072, or call 1-800-543-4330.

AM Radio Log

The National Radio Club's 17th Edition of their *AM Radio Log* is now available. Its 312 pages list the US and Canadian AM broadcast stations by frequency from 530-1660 kHz, with a cross reference by call letters and city. The listing includes the call, address, format, networks, phone number, day and night powers, antenna, time zone, and slogans. With 191 listed stations on 1230 kHz, a person could make a career out of logging everything on one frequency. The list comes on 8-1/2" x 11" paper, punched for a binder. The Club also has lists available of Latin American, European, and all other stations. Box 164, Mannsville NY 13661.

LETTERS

Continued from page 83

Last year, Bob Gobrick WA6ERB/VOIDRB and I sat in the QRP-ARCI hospitality suite and kicked around an idea we hoped would change this. Coming from engineering backgrounds, we both have extensive experience with technical conferences and trade shows. And what else is Dayton if not a trade show with a few technical conferences thrown in? We thought that a QRP technical conference would enhance everyone's enjoyment of the QRP activities, and perhaps even raise their level of technical knowledge.

We envisioned some of QRP's "great white heads" holding forth on topics of interest to all: what's the best antenna, what's the best band, how do radios really work, how do you build a radio, etc. We decided on the Thursday before the Hamvention opens. We thought there might be 20 or 25 of our fellow QRPers who'd use up an extra day of vacation and spring for the extra expenses. Surprise, surprise—we had 105 enthusiastic QRPers in the audience. Dayton Bombed? Not at the Day's Inn—Dayton South! Yes, we're going to do it again next year, and you have my personal invitation to attend, free, on me!

How can I pass up a free meal? Meanwhile, Bruce, the more articles I can publish on QRP, the bigger turnout you'll have, so let's see articles on QRP rigs, reviews of kits, and so on. What's the best backpack antenna?... Wayne.

Evan Rolek K9SQG. Your "How About Macs" editorial really got me going. Hams demand no-tune transceivers. They want automatic antenna tuners to match the impedance of their linears, keyers, voice synthesizers, automatic CW copiers, and motorized crank-up towers, so one might think that hams are lazy. But for some unknown reason they have an obsession with PCs and shun Macs. I heard a chap explaining proudly that it only took him two days to get his CD-ROM installed and working. With a Mac, even a novice can get a CD-ROM working in less than 10 minutes. I used to joke with PC users because, unlike with the Mac, they could only use eight characters to name files, and no uppercase, commas, blank spaces, etc. Now, with Windows 95© they're saying, "Hey, you know, I can name my files now!" Just compare the number of help books and help courses at local schools for PCs vs. Macs. Missed you at Dayton.

Golly, Evan, you convinced me!... Wayne.

Don Blackys K9UQN. I just got through reading your editorial called "Debacle?" in the September *73*. My response to your comments is that you are applying what happened to us as youngsters to a new time and place. That is difficult to do. In your opening paragraphs you speak of that nasty group called "hams" who provide the least in the way of benefits to the public in return for their use of billions of dollars of spectrum. Really? I started on the ham bands back in 1959 with a Novice license. Today I hold the amateur Extra, all four FCC Commercial licenses, a masters degree, and have the title Systems Design Architect and Engineer, Motorola Land Mobile Products Group. I am designing some of the most sophisticated digital encrypted land mobile products that will benefit an entire world of people. And those products encompass everything from better spectrum utilization to the most "uncrackable" encryption methods to be used for customers like United States Secret Service, FBI, US Border Patrol and US military customers. And where did it all start and where does it continue? With my love for radio, which was sparked by ham radio back in 1959. Our company has many hams working on hundreds of diverse projects to aid mankind now and in the future, and this includes using microprocessor controls for everything from the cars we drive to the microwave ovens we cook in. Where did these engineers get their start? Ham radio.

Yes, Wayne, it appears on the surface (to you) that amateur radio is becoming a waste. And if you look at Dayton on the surface, yes, there are some real lowlifes that are entering the hobby, but they are the same lowlifes that take up a slot in life, drink beer and don't give a hoot for their country and/or fellow man.

You made a statement that alluded to ham clubs not helping youngsters understand radio and electronics. Have you ever taught a class recently? I have taught over 400 people now everything from the Novice through Extra and the Commercial FCC exams. You know what everyone wants today? They want a license to either chat on the radio or get a job they won't be able to handle. It has nothing to do with ham radio: it has to do with the fundamental idea that our government in this country has encouraged: That failure is OK, reading books is boring, and you get a job just because you are a minority. The kick-ass, get-tough, dig-in-and-fight attitude is gone in the United States. Look at how simple the ham exams are today. I teach the no-code in four evenings and have had 75 students so far score no less than a 90 on any element they take. Where's the 1960 attitude of "Two-thirds of you just flunked your Extra theory (1) questions, of which 10 were draw-the-schematics)"? We have become a soft, give-away country, Wayne. Why not ham radio? Give it away to a bunch of morons whom the government can then control. That's the bottom line.

I go through this every day—seeing newly graduated engineers who got straight A's in engineering school not be able to tell me how RF energy gets from the transmitter to the antenna down a coaxial transmission line. They have no idea, yet when I check their records: An A in Fields class. Give the grades away so our colleges can remain in business.

Straying away from ham radio for a minute, I am also a private pilot with an instrument rating. I have talked to many of my ham buddies who fly as captains with major airlines. I have asked them point blank, "Is there a movement in the United States to get rid of private pilots in American airspace?" The answer has been a resounding "Yes!" Might as well, Wayne; they fit your guideline of "least benefits to the public in return for their use of billions of dollars of spectrum (airspace)."

Say what you want, Wayne, it's your magazine and your feelings. But don't blame ham radio. It has and will remain a vehicle for people to have fun with electronics and explore the field of RF communications. Who knows who the next engineer we hire will be. He might be the kid we are looking for to develop a new encryption method because he has been reading in depth on digital coding methods—something that was a spin-off of high-speed packet radio operation. I hope you will lighten up, Wayne.

Don, I'll lighten up when I see some articles coming in from you to help get the readers interested in pioneering ham digital voice communications. But my main message is that either we start cloning hams like you in quantity or we're goners. Sure, we have a few youngsters coming into the hobby and going for high-tech careers, but it's about one-tenth as many as we used to provide the electronics industry. Meanwhile the industry has grown by a hundred times, and shows no sign of slowing down. Don, I read a thick stack of ham club newsletters every month and only a few show any signs of serious recruitment and giving theory classes. Our kids' low grades and lack of motivation are a product of our government-controlled school system. If we can get the government the heck out of our schools (and a bunch of other similar expensive failures) we'll be a whole lot better off. Eventually if there's no quid, there isn't going to be any quo... Wayne.

Don Lawshe NW2S. In reference to obtaining adhesive-backed copper foil for antenna construction, any craft dealer worthy of the name handles this tape, generally in the "stained glass" section. My

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)—comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

The deadline for the April 1997 classified ad section is February 12th, 1997.

local dealer has it for $3.49 for 12 yards. A nationwide distributor is Dick Blick Art Materials (800-723-2787); their item number is 606-3601, price $3.20 for 12 yards, plus shipping. However, be sure and get *copper* tape, not the lead tape some dealers also carry. The copper foil (tape) originally was intended to wrap the edges of "Tiffany" type stained glass ornaments and windows.

OK, antenna weather is here—still winter, so I want to see a bunch of "Curses, Foiled Again" antenna construction articles... Wayne.

Craig Roberts WB5HKO/1. I've just read your wonderful editorial on entrepreneurship. Good job! A year ago I was an out-of-work advertising copywriter and ex-radio announcer feeling terribly sorry for myself; abused by society and victimized by a "bad economy." My pathetic mood was exacerbated by the necessity of selling the contents of my modest shack in order to meet a mortgage payment. My God, evil and overwhelming forces had forced my to give up not only my dignity as a family provider, but the trappings of my beloved hobby as well. Things couldn't be worse! Woe was me. Then, during one of many telephone calls to "Help Wanted" advertisers I was put on hold. While in that telephonic limbo, I heard several minutes of informative promotional messages for the company I had called. "Hmmm," I thought, "I could do that. I could write, produce and sell telephone on-hold messages." The disciplines involved were well within my professional capabilities and the investment needed to get into the business was nearly zip. I excitedly told a few friends about my plan and was met by doomsaying: "Start your own business in conservative old New England? You must be mad! The economy's terrible and no one will buy your radical service!" Having nothing better to do, I persevered. I went door to door taking orders and small deposits. With the deposit money I rented some audio equipment and delivered on my promises. It worked wonderfully. Mine isn't the largest on-hold company in the country, but

PROPAGATION

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

February is likely to be a rather "blah" month (again) for DX propagation due to generally depressed seasonal and cyclical solar flux values, which have hovered in the high 60s and low 70s for almost a year. However, it is expected that there will be favorable increases in solar flux—hence DX propagation—during late summer and fall.

On the brighter side, noise levels (QRN) should be fairly low this month, and few days are expected to present any great storm activity in either atmosphere or ionosphere. You may want to try your DX ability on the 6th, 11–12th, and 21–22nd while avoiding the days surrounding the 3rd, 17th and 27th.

Listen often to WWV at 18 minutes after any hour. The 10 MHz frequency is best for me but you may wish to try 5, 15 or 20 MHz for best reception at your QTH. Best "conditions" will appear when the "A" and "K" indexes are low (Boulder K less than 3 and A less than 10) with accompanying solar flux values moving upward into the 80s and 90s.

Don't give up...better times are coming, and the skills you develop now will stand you in good stead when propagation improves. W1XU.

10–12 meters

A few possible daytime F2 layer openings to South and Central America on the Good (G) days.

15–17 meters

Fair DX openings on Good (G) days between noon and sunset, and short-skip openings during the daylight hours. The band dies at sunset.

20 meters

DX to most areas of the world during daylight hours, peaking a few hours after sunrise and again during the early afternoon. Although the band usually closes soon after sunset, you may find occasional openings to South America and Antarctica until midnight. Daylight short skip from several hundred to 2,000 miles or so possible on most Good (G) or Fair (F) days.

30 meters

DX toward Europe in the late afternoon and evening on Good (G) days until midnight, and then toward the Orient in the early sunrise hours. Possible long-path DX in the morning and also short skip most days out to a thousand miles or more, and farther in the evening.

40 meters

DX toward Europe and Africa in late afternoon hours, toward South and Central America around sunset, and good openings to the West and South Pacific peaking around sunrise on Good (G) days. Expect daytime short skip to 1,000 miles, and 2,000 miles at night.

80–160 meters

Both are excellent bands for DX during hours of darkness, peaking at midnight and just before dawn. Daytime skip on 160 is nonexistent, but on 80 it can be up to 500 miles, and over 2,000 miles at night. On 160, short skip can reach from 1,000–2,500 miles at night. Experts prefer vertical polarization for transmitting antennas (low-angle signal take-off) and horizontal polarization for receiving antennas (less noise) on 160 meters.

Antenna Books

UE220 **The Easy Wire Antenna Handbook** by Dave Ingram K4TWJ. All of the needed dimensions for a full range of easy to build and erect "sky wires." $9.95

WGP87034 **All About Cubical Quad Antennas** by William Orr and Stuart Cowan "The Classic" on Quad design, theory, construction, operation. New feed and matching systems. New data. $13.95

TAB 3270P **Practical Antenna Handbook**-2nd edition by Jos. Carr. This 560-page book is a treasure. Starts with fundamentals, explains propagation of all kinds, and provides a ton of easy antenna projects. $29.95

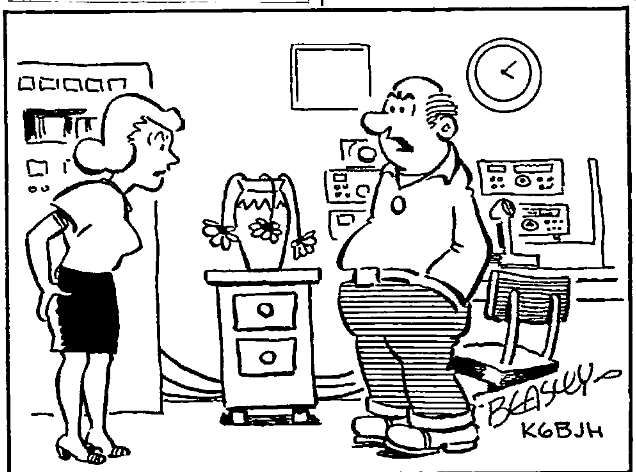
AR4734 **ARRL Antenna Book.** Best and most highly regarded info on antenna fundamentals, transmission lines, design, and construction of wire antennas. $30.00

WGP87107 **All About Vertical Antennas** by William Orr. Comprehensive coverage of amateur communications. $13.95

WGP87042 **Beam Antenna Handbook** by William Orr and Stuart Cowan. Everything you need to know about beam design, construction, and operation. $13.95

WGP87077 **Simple, Low-Cost Wire Antennas For Radio Amateurs** by Willliam Orr and Stuart Cowan. Low-cost, multi-band antennas; inexpensive beams, "invisible" antennas for hams in "tough" locations. $13.95

AR4661 **ARRL's Antennas & Techniques for Low-Band DXing** can be your ticket to low-band success. $20.00



NO, IT'S NOT HIGH-ENERGY ELECTRO-MAGNETIC FIELDS IN THE SHACK--- I JUST FORGOT TO WATER THE @#!!★ THINGS!

HAM HELP

We are happy to provide Ham Help free on a space-available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double-spaced, on a full 8-1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully. A 1, for example, can be misread as the letters I, i, l, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Any Yaesu Hints?

I have a Yaesu FT-51R-HP Dual Band Transceiver with high power battery pack, digital display microphones and cigarette lighter adapters. The unit will not stay on high power but reverts to a lower power setting. How can I achieve the specified 5 watt output from this radio and how can I get it to stay on the high output setting of 5 watts when it is selected? Yaesu has already fiddled with this unit and returned it to me but the problem still occurs. Please respond to *George T. Platt N1UUN, P.O. Box 21, Guild NH 03754.*

Pirates of the Caribbean

The hams of Guantanamo Bay are in a quandary. Rusty Auxier KG4AU, President of the Guantanamo Bay ARC (KG4AN), writes:

"We have about four hams here who are active on HF, and it is sometimes difficult to QSL due to the fact that our club call, KG4AN, has been deleted from *Callbooks* for the last few years. I just received my copy of *Radio Amateur Callbook* on CD-ROM, and discovered my stateside call said 'QSL via KG4AN' but there was no address for KG4AN. Of course, people wishing to QSL can go through the bureau, but that adds a lot of extra time. The QSL route for any KG4?? hams is as follows:

G.A.R.C./ ATTN: KG4??
PSC 1005 Box 73
FPO AE 09593-0173.

"By the way, there are several pirates out there using KG4 callsigns. A few known ones are KG4AA, KG4AB and KG4US. Here is a list of the active hams who are live on the island:

KG4AU - Rusty Auxier
KG4WD - Wayne Duncan
KG4KD - Kim Duncan
KG4CQ - Tom Mann
KG4HE - Ray Magorno

"We do have visiting hams here on a regular basis, most notably KG4GC, Bill Gallier. If there is any doubt about the validity of a call, you can write us at the above address, ATTN: KG4AU, or for those hams on-line, the E-mail address is Rustman@AOL.COM."

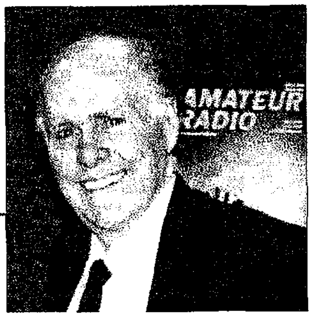
NEVER SAY DIE



Wayne Green W2NSD/1

School Finally Reinvented

As I keep mentioning (endlessly, I guess), our compulsory public school system really sucks. And (ugh!) it's getting worse. Having totally failed to get you to do anything about this miserable situation, I've been doing a lot of research. I've written about what's going on and made some proposals for improving things in my *Declare War* book, plus also in several segments of my *20/20 Foresight* series. I'm busy updating both of these out-of-print books, by the way.

Many schools have been experimenting with ways to improve things, and in most cases their ideas have been helping. You know, it's been shown actually possible, even in the worst inner city ghettos, to get parents actively involved in their children's education.

But the best model school for the future that I've heard about, by a wide margin, is the Sudbury Valley School in Framingham, Massachusetts. I'd class this as the best school in the country. No, probably the best in the whole world! It's a model of iconoclastic, innovative thinking. A reader suggested I look into the school so I sent for a book about it and, when I read it, I got really excited. I'd say this is probably the single most important book I've ever read.

How about a school with no classrooms, no regular classes, no grades, no tests, and no curriculum? How about a school that is so superb that every graduate desiring to go to college has been accepted by a college (usually the one of their choice), despite there being no grade transcripts available, or even a teacher evaluation? How about a school for kids from four to 18 where they learn what they want to learn, when and if they want to learn it, and with no pressure from anyone but themselves to enforce learning? Not even the parents! How about a school where kids can learn eight years of math in 20 contact hours—just because they want to? Where kids read voraciously because they want to?

For most things the kids teach themselves, but when they want help from a teacher it's available. The end result is a bunch of very self-reliant, self-motivated kids with top notch educations, kids who keep right on learning all through their lives.

Spend the $7 for the book, plus $2 shipping for *Free at Last* by Daniel Greenberg, and eat your heart out that you didn't have the opportunity to go to a school like this. Maybe it's time to start one in your town. Order the book immediately, before you forget, from Sudbury Valley School Press, 2 Winch Street, Framingham MA 01701.

Here's a school where every decision is made by the students and teachers together, where there are no administrators, no graffiti, where the students do all the maintenance, where there is no government funding, yet the school costs less than half as much as a public school per student, and yes, it's accredited.

The fact undiscovered by our public school teachers, teachers' colleges, and school administrators is that you cannot *force* children to learn. Oh, under pressure (via ridicule and humiliation) they'll memorize enough to pass tests. But 95% or so of that stuff is gone by the next semester.

In college I began to understand this. When I'd have a problem with a course I was taking I'd ask an upper classman in my fraternity for help. The answer was always the same, "Oh, I passed that course. I don't remember much of it. Sorry."

It really came home when I went back to college after World War II. I'd gone for two years before the War came along and the local draft board decided I would be of more value in the trenches than sitting around in class. So I joined the Navy. You can read more about my exciting adventures (we came tha-a-at close to being killed several times) in my *Uncle Wayne's Submarine Adventures in WWII* book.

During the first two years of college I suffered through four semesters of calculus. I really suffered. I hated it. I wouldn't have hated it so much if the teachers had been able to give me any idea of what I might be able to use it for. Yes, I kept asking, and it just made them mad. The best explanation I was ever able to get was that if I wanted to find out how big a sphere I could put into a cone, calculus would help. You know, it's never come up! Nor, in my 45 years of publishing technical articles, has there been any serious need for me to deal with calculus.

Anyway, after being away for four years, when I went back to college (paid for by the government under PL-16) I still had one more term of required calculus to go. The trouble was, when I opened my old calculus book to refresh my memory, I found I had no memory. It was just as if I'd never been through those two years of misery. So I spent my summer going back over the old material, re-memorizing a bunch of stuff that didn't make much sense. I had to "learn" it all over again. Grumble. And all that for a totally useless differential equations course, which mainly involved my memorizing hundreds of equations. We never were given any practical applications, so I still don't know what that was all about.

College was an agonizing blizzard of memorizing for tests. I have little recollection of anything that went in and out of my memory at the time. Nor has much of that ever been of the slightest value to me in life.

The Sudbury Valley School has shown that if you leave kids alone they are harder task masters than teachers ever would be. They learn what they are interested in, when they are interested. Not one of the "buts" you're going to come up with is valid in the real world.

Our public schools, as I've discussed before, were modeled on the Prussian military schools, whose purpose was to turn out obedient soldiers who would follow orders without question. But is that really what you want for your kids? Well, that's what you're getting, and you're going along with it.

Most of you are too old to have kids in school, but you do have grandchildren, so send for a copy of the book for each of your children. It'll be one of the best $9 you ever invested.

Oh yes, my university. When I was back there recently as a member of the RPI Council, I was assured by the president of the student council that nothing has really changed, that the university still operates on the basis of memorization and tests. And sure enough, they're still teaching classes with rows of desks and blackboards. Wow! Right out of the 19th century.

One Sudbury Valley School graduate put it this way: "Public school systems are set up as dictatorships, which is why children who develop in public school systems end up the same way that prisoners in prisons develop: they tend to become mentally sluggish and submissive." Hmm, so *that's* my problem!

Mooned Again

Yes, of course I realize that the whole idea of all those moon landings almost 30 years ago being a giant hoax is so ridiculous that Wayne Green is off his rocker for even reading about such nonsense. I used to figure that the 30% of the American public who didn't believe we'd ever been to the moon must be a bunch of ignoramuses. Then René's book, *NASA Mooned America* arrived one day in the mail.

Well, I get all kinds of weirdo baloney in the mail. The Iraqis

From the Ham Shack

George Bergstrom, Rancho Cordova CA. Your appearance on the Art Bell show was fascinating. Being an electronics hobbyist I decided to build a "purifier" from your description. Here's the schematic I put together (**Fig. 1**). Your "AIDS Info" booklet recommendation to drink 8 oz. of water before and after is apparently important since I don't drink much water unless it has Sanka in it and ended up with two nearly painless boils on my back, which quickly cleared up. I've already noticed improvements in my skin and nails. I started with one salt pad at the ankle and the other just below the knee, but now I'm using one at the left arm wrist and the other above the elbow.

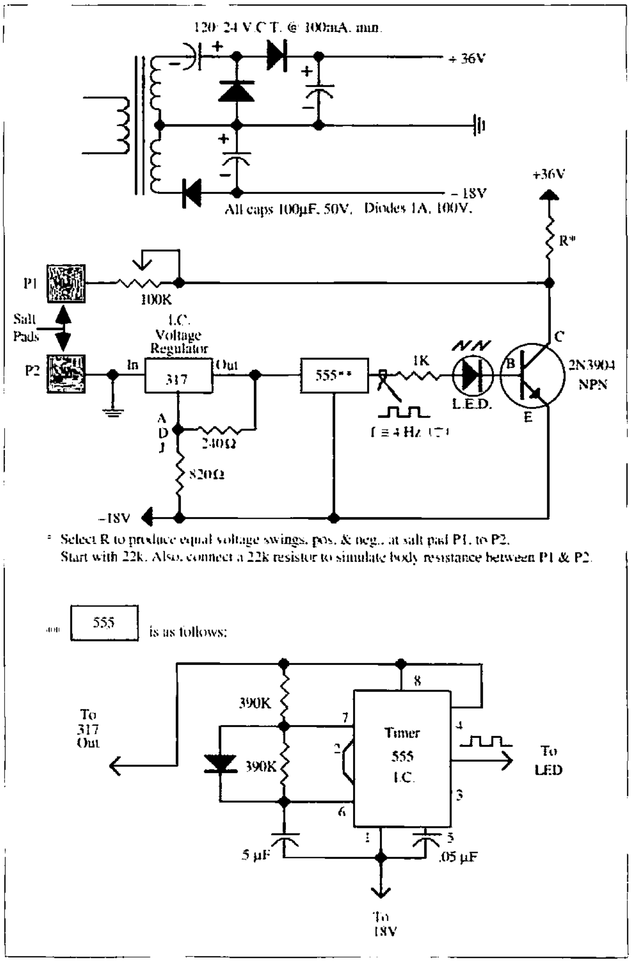

Fig. 1. George Bergstrom's purifier.

Ron Gang 4X1MK. As I look through the different amateur radio publications, indeed almost all of them, I see some interesting soul-searching. Ideas which not too long ago would have been considered heretical have now even popped up on the pages of the rather conservative *QST*. To sum it up: You can now pass messages and even voice to any spot in the world on the Internet. The financial outlay on the hard and software, plus local telephone calls, is cheaper than that of a ham station with good worldwide communications capabilities. And, of course, the Internet isn't affected by sunspots and doesn't cause TVI. Emergency communications? Cellular telephones are almost universal, so help can be easily summoned. No need to hope that someone else is on the repeater and can make a phone call for you when you're in trouble.

Now, as you probably know, this past spring we experienced some ghastly terror bombings. When the bombing massacre occurred at Tel-Aviv's Diezengoff Centre shopping mall during the Purim school holiday, the national telephone network became so overloaded by phone calls that the system crashed and all telephones were temporarily rendered useless. Hams jumped in to help on the Tel-Aviv 2 meter repeater, this being the only workable communications at the time.

A week later, after driving some friends to the airport, my car broke down. On the Tel-Aviv repeater one ham took care of the phone calls to my home while another ham, a mechanic in the general vicinity, drove over to where I was stuck to help me out. The day before that I was in Jerusalem, and accompanied by a non-ham friend, I dropped in to an informal ham get-together. My friend was impressed by the warm manner of the group, and commented on our way home, "You must be really good friends with all these people." Actually, I had only seen them face-to-face on a few occasions, but we had been talking together on the radio for years.

Then it hit me. Ham radio is much more than just a mode of communications. Ham radio is friendship. Ham radio is a fraternity. Ongoing contacts build a community of people who are not strangers to each other. Ham radio counters alienation. Thus the willingness to help each other, to host visiting amateurs from other countries. People is what ham radio is all about.

The actual mode of communications via radio was not long ago technically beyond the general public. But for most of us that was not necessarily the attraction of it. Now that the Internet and cellular phones have liberated amateur radio from having to be "useful," it is simple to see what distinguishes it from the former. Ham radio is an art form. We are into it because we like it for what it is. In the words of the "global village" guru Professor McLuhan, "The medium is the message." Long live ham radio!

Yep, Ron, we certainly have a great fraternity. Now all we have to do is convince the FCC and Congress that international conviviality is worth a few billion dollars worth of radio spectrum... Wayne.

Mike Miller WA8YKN. Just a quick update. I recently sent a Bioelectrifier to Dr. Val Hutchinson of Amarillo, Texas. Last night he called to say that while monitoring his body during using the device, that his temperature went up 1.5 degrees. This was repeatable. This might explain in part the results, since viruses and bacteria are easier to kill at an elevated body temperature.

I've been getting calls about successes with a variety of ills with the device, and no reports of failure so far... Wayne.

Ernie Stricklin, Cherry Grove AB. I just wanted you to know my results with the Bioelectrifier. I just used 2N2102 transistors in a multivibrator. Being silicon, they can stand up to 50V on the collector. I used 30V and took off from the collectors of the two transistors with electrodes made of two pennies with 68K resistors in series for pulsing my veins. It works perfectly and reduces the circuitry to just a multivibrator. If you use MOSFET circuitry the multivibrator can be two NAND gates in an IC. The results? Well, I don't have AIDS, but after less than two weeks I've gone from 183 pounds to 167, and I've never felt better in my life. It's a big relief to get rid of those extra pounds.

Curses, Foiled Again!

In the August issue I ran a letter from W4FA grumbling about

finding copper foil for making weenie antennas. Both W4FA and I should read the ads more closely, for there, on page 71, was an ad by Hamco, offering copper foil tape at reasonable prices. Call 303-795-9466 and ask Larry Feick. If you're too cheap to call, invest a lousy 32 cents in a letter to 3333 W Wagon Trail Drive, Englewood CO 80110.

Get yourself in gear and start peppering me with articles on the great antennas you've designed with this stuff. We're into good antenna weather, when there's lots of snow and ice to make antenna raising memorable. I know I'll never forget putting together a twin-three antenna in the yard of my fraternity house wallowing around in three foot of snow. Every time I put the soldering iron down it disappeared. But, hoo boy, did that antenna ever work out! I've put up some pretty big beams since then, but none have ever given me the reports I got with two of those wire antennas hung at 90° from each other from the fraternity house to trees on the edge of our yard. My ham station filled the basement.

Okay, you have your instructions. Design, buy foil from Larry, build, check it out, write, take some darned good pictures, and don't forget to send me a disk copy of the text... Wayne.

Phillip Holmes, Van Wert OH. Jim Gray gives more credit to HAARP than the project deserves. There seems to be some eagerness to attribute capabilities of Dr. Bernard Eastland's patents to this classified project. Unless HAARP is somehow manipulating the Earth's magnetic field to produce much higher energies than the system itself is broadcasting—well, the power is just not available to carry out the controversial aspects.

There is no doubt in my mind that a BLACK PROJECT EXISTS and has existed since at least the early 80s, that can do some very spectacular geophysical alteration for a variety of national security reasons. This black system is most likely space-based, operating in conjunction with the Space Shuttle fleet.

According to my local paper, dated 1991, atmospheric scientists from nine federal laboratories including Los Alamos and Philips Laboratory (the HAARP manager) created artificial Northern Lights and auroras in the Earth's magnetic field. A scientist called the displays "as bright as any phenomenon in the sky outside of the sun itself." This astounding airglow experiment would seem to require a much larger system than the proof-of-concept system that HAARP actually is! Without the attenuating effects of the atmosphere, a space-based system could be smaller, require much less power and be highly portable.

From my study, I believe Challenger, 41-C, in conjunction with Solar Max, carried out a classified deep-Earth tomography mission, utilizing the natural electrical forces of the Earth (the polar electrojet) on 9 April 1984, near the Kuril Islands off the northeast coast of Japan, over Soviet territory. The goal of the mission was to locate a secret underwater submarine pen housing the then new titanium-hulled Typhoon missile boat by using an ELF radio-wave technique. There was a spectacular geophysical anomaly that appears to be related to this mission—The Mystery Cloud of 1984. Hope you find this of interest.

Jeff Anglesey KB7TJM. Your magazine is most excellent, and I buy it instead of *CQ*—too boring. Your technical contributing editors are great. Each issue always has something I can use. How about doing an article on low budget satellite operating? I use an HTX-202 running 5 watts to a 5/8-wave mag mount for the uplink and an AOI AT-400 HT and homemade 6-element yagi for the AO-27 downlink.

You forgot to mention how much you enjoy my editorials... Wayne.

David Borba KC6UMX. Great magazine! I first heard Wayne on the Art Bell (W6OBB) radio show, bought one of his magazines and was hooked. It is educational finding grid squares from coordinates, and the *Radio Fun* section describing types of emissions, and also it is open forum—like W5UOJ's treatment of closed repeaters in the July issue—something I always agreed with, but never said anything about because I thought it was "status quo." I would rather see a magazine like this with articles on HAARP, Tesla, cold fusion and other diversions from radio than to read a magazine with pages and pages of contest news and name lists. Hang in there, Wayne, I want to read "Never Say Die" for many years to come.

Non illegitimi carborundum... Wayne.

Michelle "Missy" Hollenbeck AAØOF. Today, Joseph, one of my eighth grade students, just passed the Novice theory test and the 5 wpm code test. Joseph, his family, his classmates, and the area ham radio operators (including me, of course!) are proud of his accomplishments. Joseph has learned that patience, practice, and extraordinary work do bestow a sense of self-satisfaction.

I'm writing you, Wayne, to reassure you that my students are exposed to as much technology as possible. I know that you are truly concerned about today's youth involvement in amateur radio.

Many skeptics say that the Internet will replace amateur radio, but in my classroom, the Internet and amateur radio work hand-in-hand. All the great things that we do in amateur radio are "highlighted" on the

Continued to page 63

QRX . . .

New FCC RF Safety Rules

As of the beginning of 1997, hams are responsible for new exposure limits (see Table 1). Maximum Permissible Exposure (MPE) limits have been set for electric and magnetic field strength and power density for transmitters operating between 300 kHz and 100 GHz. This ends a long waiver of these limits for ham operators.

We must ensure that if our stations operate with more than 50 watts of output power the listed MPE limits are not exceeded.

TNX to *Hill Country ARC Newsletter*, December 1996.

FEMA Backs Hams On Spectrum Sharing

The Federal Emergency Management Agency, better known as FEMA, is saying no to sharing or reallocating the 2m and 70cm ham bands to Low Earth Orbiting satellites. In a letter to the FCC task force currently evaluating new spectrum for use by LEO satellites, FEMA Manager Paul Reed tells the committee that his agency opposes any such change.

Reed says that Amateur Radio operators have a history of supporting state and local government emergency operations by providing needed communications. He says that many local communities served by ham radio have extremely limited resources and would be without any form of backup communications without Amateur Radio.

Reed says that FEMA has been in contact with its state and local emergency management partners across the nation. It is their belief that authorizing access to the mobile satellite service in the 2m and 70cm bands will seriously degrade the ability of these groups to support their public service requirements.

The FEMA Manager ends his letter by strongly urging the FCC task force to remove both of these ham bands from any further consideration as a new home for Low Earth Orbiting Satellites. He says to leave them for use by ham radio and its emergency service partners nationwide.

From *The Tuned Circuit*, monthly bulletin of L'Anse Creuse ARC. Utica MI, January 1997.

Limits for Occupational/Controlled Exposure (Environments where people are aware of the potential for exposure and can exercise control over their exposure)				
Frequency Range (MHz)	Electric Field (V/m)	Magnetic Field (A/m)	Power mW/cm2	Averaging Time (min)
0.3 - 3.0	614	1.63	(100)*	6
3.0 - 30	1842/f	4.89/f	(900/f)*	6
30 - 300	61.4	0.163	1.0	6
300 - 1,500			f/300	6
1,500 -100,000			5	6
Limits for the General Population/Uncontrolled Exposure (Environments where the general public may be exposed)				
0.3 - 1.34	614	1.63	(100)*	30
1.34 - 30	824/f	2.19/f	(180/f)*	30
30 - 300	27.5	0.073	0.2	30
300 - 1,500			f/1,500	30
1,500 - 100,000			1.0	30
f = Frequency in MHz * = Plane-wave equivalent power density				

Table 1.

Iran May Issue Ham Tickets

Iranian hams may soon be heard on the air. The British Broadcasting Company's monitoring service reported in November that the Iranian Ministry of Post, Telephone and Telegraph soon will issue Amateur Radio licenses to Iranian citizens. The BBC quoted the Teheran-based English-language newspaper *The Iran Times*. According to the report, the Iranian Ministry has invited radio enthusiasts over the age of 16 to sign up for special Amateur Radio license training.

From December's *The Garden City Wireless*, newsletter of Garden City ARC, Garden City MI, who got it from *Amateur Radio Newsline*.

(*Will women be licensed as hams in Iran, too?* —Ed.)

Does Your Bread Land Jelly-Side Down?

- Mobile antennas fail in the first 100 miles of a 1,000 mile trip.
- Manuals mysteriously disappear just before you want to sell a radio.
- Sellers always have whatever you want back at the shop.
- Rotors fail on contest day at 2 AM.
- As a seller, you never arrive early enough at the hamfest for a cool shady spot.
- You never have the correct value replacement fuse.
- Battery chargers are always left at home.
- CW is never slow enough to copy at Field Day.
- No two Atlas 210s work the same.
- You always find that other lost gizmo while you're looking for the first lost gizmo.
- The accessories for your old HT or mobile are never compatible with your new HT or mobile.
- Elements of antennas that need to be adjusted are always just beyond your reach from the top of the tower.
- Women and children grasp CW faster than the OM.
- The polarity of the radio's power cord connector of the unit you want to demo is always wired opposite to the one you have with you.

Getting Ready for Phase 3D

Start now to be prepared for amateur radio's next great adventure.

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

Phase 3D is the largest, most complex international hamsat project to date. This amateur radio satellite is currently under construction and in final test at the AMSAT lab in Orlando, Florida. It is scheduled for launch from French Guiana in July on board the Ariane 502 booster. This will be the second flight of an Ariane 5 rocket, hence the "502" designation.

The first flight of an Ariane 5, on June 4, 1996, failed. Only 37 seconds after ignition, at an altitude of 12,000 feet, the launcher veered off its flight path, broke up and exploded. This has caused significant delays for the flight of Ariane 502. An inquiry board investigated the failure, furnished an analysis and provided recommendations for subsequent operations.

The Ariane 501 flight exhibited nominal behavior up until 36 seconds after initiation of the flight sequence. At that point there was a simultaneous failure of the two inertial reference systems, which caused the nozzles of the two solid-rocket boosters, and then the main liquid-fueled engine, to swivel into an extreme position. This made the rocket veer abruptly and triggered an automatic self-destruction sequence due to the rupturing of the electrical links between the solid boosters and the vehicle core.

The post-flight analysis report from the independent inquiry board concluded with, "The failure of Ariane 501 was caused by the complete loss of guidance and attitude information 37 seconds after start of the main engine ignition sequence (30 seconds after lift-off). This loss of information was due to specification and design errors in the software of the inertial reference system. The extensive reviews and tests carried out during the Ariane 5 development program did not include adequate analysis and testing of the inertial reference system or of the complete flight control system, which could have detected the potential failure."

Spaceflight is risky business. AMSAT's Phase 3A spacecraft was lost on the second flight of an Ariane 1 booster 17 years ago. When the Ariane 501 booster failed last year, it was a major setback to the European space program. The loss was estimated at nearly a half billion dollars. The Ariane 5 program is pivotal to the planned manned-space activities from Europe. The success or failure of the Ariane 502 launch will determine whether Europe moves forward with their ambitious goals, or regroups. The launch campaign will begin on Wednesday, April 9th. Efforts to ensure that all goes well are at an all-time high.

"Spaceflight is risky business."

Then and now

The Amateur Satellite Program has come a long way since the launch of OSCAR-1 on December 12, 1961. OSCAR stands for Orbiting Satellite Carrying Amateur Radio. OSCAR-1 was built by Project OSCAR, a West Coast group. The launch took place only four years after that of Sputnik-1 from the Soviet Union. OSCAR-1, weighing in at 10 pounds and costing about $64, carried a 140 milliwatt CW beacon transmitting "HI" on 145 MHz. The transmissions lasted 22 days till the satellite re-entered the atmosphere from its very low Earth orbit.

Since then there have been many amateur satellites: some simple, and others supporting many complex experiments and transponders. We have had satellites with CW telemetry beacons, several with analog transponders like repeaters in the sky, and others with complex, digital store-and-forward flying BBSs, or radio bulletin-board systems.

Work on the Phase 3 series of hamsats began in 1975. While Phase 1 satellites were designed for low orbit and short life, and Phase 2 types were low orbit and long life, Phase 3 was initiated to provide high elliptical orbits, long life and reliable communication. AMSAT-OSCAR-10 (Phase 3B) was the first Phase 3 satellite to achieve orbit. It was launched in 1983. Although the batteries have quit, the satellite still works when the solar panels are properly illuminated. AMSAT-OSCAR-13 was sent to orbit in 1988. Due to the gravitational effects of the moon and sun, it re-entered the atmosphere in December 1996.

When Phase 3D achieves orbit it will be given an OSCAR number. It is much larger, heavier, more complex and more expensive than its predecessors. The main body is nearly seven feet in diameter and three and a half feet tall. With solar panels extended, the wingspan is over 20 feet. The satellite weighs in at around 500 pounds with an estimated program cost of 4.5 million dollars.

Support for this immense program comes from AMSAT groups around the world. No one ham organization has the resources to plan, build and get a ride to orbit for a satellite of this magnitude. Funding for Phase 3D is

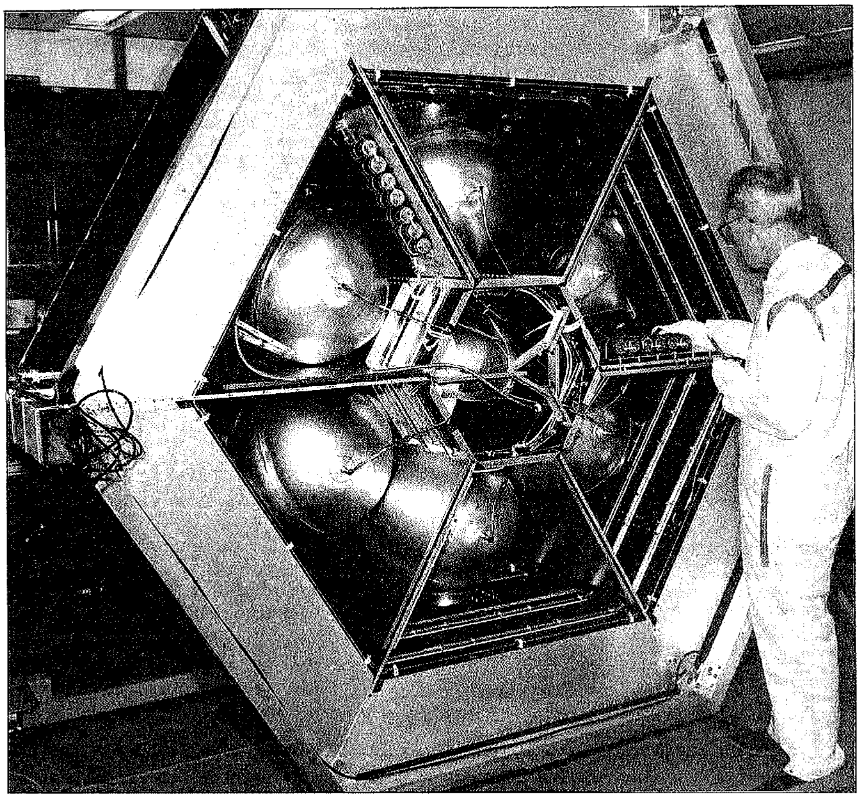

Photo A. Dick WD4FAB adjusts the mockup battery pack on the -Z axis of Phase 3D.

derived from membership dues, individual and corporate donations. The American Radio Relay League has been instrumental in financial support of the 1.5 million dollars (cash, labor and components) pledged by the North American AMSAT.

What is AMSAT?

AMSAT is a worldwide assembly of amateur-radio operators who share an active interest in building, launching and then communicating via non-commercial, amateur radio satellites. The collective groups of AMSAT organizations and companies around the world have been responsible for the design, construction and coordination of over two dozen amateur radio communications satellites in the last 28 years.

The original AMSAT (Radio Amateur Satellite Corporation) was founded in 1969 in the District of Columbia as a non-profit, educational organization dedicated to fostering amateur radio's participation in space research and communication. The first project for the new corporation was getting a launch for Australis-OSCAR-5 in 1970. This was to be the last Phase-1-type satellite, i.e., low-Earth-orbit and short life. Today AMSAT still exists as a non-profit organization with the same objectives and goals—the satellite design, construction and control continues.

> ***"Phase 3D uses a unique 3-axis platform stabilization system in conjunction with two hexagonal rings of computer-controlled magnetorqueing rods."***

Our North American AMSAT provides a vast array of services to support those interested in learning about amateur radio satellites. To help track each satellite, the AMSAT Software Exchange makes tracking software available for most popular personal computers. AMSAT also runs its own QSL bureau and awards program for satellite users.

The AMSAT Field Organization is ready to help those looking for information on a more personal level. With over 150 Area Coordinators, there are some in most localities willing to answer questions about the satellites, arrange for demonstrations or provide talks for local clubs and ham conventions.

AMSAT sponsors regular HF nets with the latest news on satellite activity and Phase 3D progress. One of the most popular nets is held every Sunday at 1900 UTC on 14.282 MHz USB. In addition there are many VHF nets around the country with similar information coverage and supplementary local items of interest. One local net, The Houston AMSAT Net, can be heard across most of North America at 8 p.m. Central time via SBS-6, Transponder 13B, 6.8 MHz audio subcarrier. It is also carried by various VHF and UHF repeaters in addition to a 160-meter retransmission every Saturday night at 9 p.m. Central time on 1860 kHz AM from WAØRCR in Missouri. For those who cannot get the satellite feed or the other local sources, there's the Internet. The Houston net is recorded for off-line listening via Real-Audio. The easiest way to get this service is to go to the URL (Universal Resource Locator) http://www.amsat.org. Find the link to "other sites," and check out "The Houston AMSAT Net."

Lots of current AMSAT information is available at www.amsat.org. There is also an FTP site at ftp.amsat.org, and up-to-date discussions about Phase 3D and other topics can be checked out by subscribing to AMSAT-bb@amsat.org. Just send a message to listserv@amsat.org to subscribe. This is not an automatic system. Paul KB5MU handles all subscribe and unsubscribe requests by hand. More information about AMSAT, telephone BBSs and nets can also be obtained for a self-addressed, stamped envelope to AMSAT, 850 Sligo Ave., #600, Silver Spring MD 20910.

Phase 3D overview

Phase 3D is designed as a replacement for A-O-10 and A-O-13, with

some significant extras. Key points include the orbit, the transponder scheme, the spacecraft orientation system and some exciting experiments.

The final orbit for Phase 3D is to be elliptical with a perigee, or low point, of 2,400 miles, and an apogee, or high point, of 29,000 miles. The apogee will always occur over the northern hemisphere. There are several steps required to reach the final orbit. After launch, Phase 3D will be in a geosynchronous transfer orbit with a very low perigee just over 100 miles and an inclination with respect to the equator of about 10 degrees. The main 400 Newton motor on Phase 3D will be used to bring the perigee up to 2,400 miles. Another firing will raise the apogee to 29,000 miles. A final firing of the main engine will be used to raise the inclination to 60 degrees. Over a period of two years the ammonia arc-jet motor ATOS(*Arcjet-Triebwerk auf OSCAR-Satellit*) will be used to adjust the final inclination to 63.4 degrees. This small motor (100 millinewtons) will also be used for minor orbital changes. The final orbit allows the ground track and rise and set times of the satellite to repeat every 48 hours.

Of the many facets of Phase 3D, Integration Manager Lou McFadin W5DID finds the transponder matrix to be one of the most exciting. Unlike previous satellites, Phase 3D has an array of radios from 21 MHz up through 24 GHz. The satellite receivers are on 21, 145, 435, 1268, 1269, 2400, 2446 and 5668 MHz. The transmitters start on 29 MHz and continue with 145, 435, 2400, 10451 and 24048 MHz. Transmitters and receivers are paired via ground control, with one exception—a transmitter cannot be paired with a receiver on the same band. The opportunities for some very interesting combinations abound and are augmented by the satellite's ability to run multiple combinations simultaneously or to match one receiver with multiple transmitters, or multiple receivers with one transmitter.

The transmitters and receivers on Phase 3D are connected to gain antennas that will greatly enhance

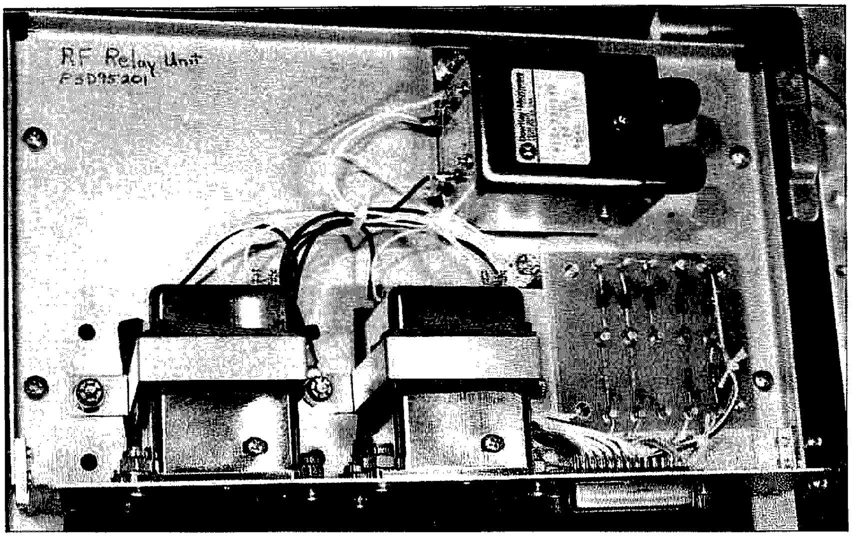

***Photo B.** RF relay assembly mounted in side 3 of the Phase 3D spacecraft. All photos courtesy of AMSAT.*

communications for those on the ground. Most onboard systems provide at least a 10 dB improvement over the previous Phase 3 satellites. This means that omniantennas will work in place of beams in many cases. On some bands the improvements will be dramatic. One of the two 10 GHz transmitters runs 40 watts to a horn antenna. A surplus DSS TV dish with appropriate hardware may be able to pick up these signals. Small "stealth" Earth stations will be a distinct possibility.

Phase 3D uses a unique 3-axis platform stabilization system in conjunction with two hexagonal rings of computer-controlled magnetorqueing rods to control both the spacecraft's attitude and spin rate. Phase 3D will not be spin-stabilized after the solar panels are deployed. Three magnetically suspended reaction wheels mounted at 90 degrees to each other are used to keep the craft properly oriented. Commercial TV satellites depend on precise and expensive bearings for their reaction wheels; Phase 3D uses a combination of rare-earth magnets and electromagnets to suspend and spin up the wheels. Each wheel is expected to consume about five watts of power for a total consumption of 15 watts.

A few of the experiments on Phase 3D include the Japanese SCOPE (Spacecraft Camera experiment for Observation of Planets and the Earth) and an array of GPS (Global Positioning System) receivers. SCOPE includes two high-resolution image sensors to provide a wide-angle and zoom view to take pictures of the Earth. The GPS experiment has changed in the last year due to difficulties with implementation of the AMSAT GPS receivers. The current system includes a pair of Trimble TANS Vector units. Each has four antennas and consumes about 7 watts of power.

Numerous papers have been written with in-depth descriptions about the features of Phase 3D. A good recent one, "Phase 3D Update," by the Phase 3D design team, compiled by Dick Daniels W4PUJ, appeared in the *Proceedings of the AMSAT-NA 14th Space Symposium and AMSAT General Meeting*. This publication, dated November 1996, contains many articles on current hamsat topics and is available from the American Radio Relay League or AMSAT for $12.00.

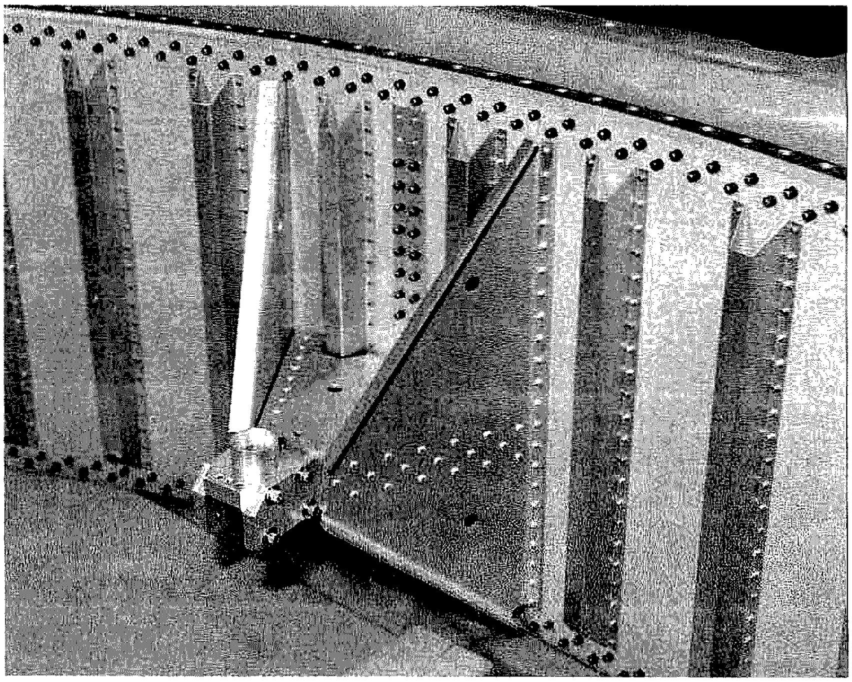

***Photo C.** Close-up view of one of the four spacecraft mounts inside the SBS ring.*

Phase 3D project status

Late last year, efforts were underway to complete all aspects of the satellite, test it, and ship it by the end of February 1997. With the recent launch delay (from April to July), more time is available to finish integration and get everything ready. A few of the December activities included work on the gas generator controller and the command arbitrator module. The SEU (Sensor Electronic Unit) had been received and work was underway to adjust antenna locations for the new Trimble GPS units. Several receivers and transmitters were scheduled to be at the lab

soon and some circuit boards for control units were nearly finished. The SBS (Specific Bearing Structure) is complete and has been approved for use on the launch. Phase 3D is to be placed inside this cylindrical structure. A conical adapter will then be bolted on top of the SBS. This will allow another satellite or test system to be mounted above Phase 3D in the payload stack.

The few remaining months before launch promise to be exciting but hectic. In order to properly test the GPS system, the satellite must be able to "see" the GPS satellites. That means that Phase 3D must be taken out of the clean room, or the clean room must be moved outside, or the antennas must be remotely located during tests. The same situation exists for a full test of the complete communications transmitter/receiver and antenna system. There are still issues to be resolved, but with dozens of successful satellites on the roll, the collective worldwide AMSAT will invent methods to handle the situation.

Getting ready for Phase 3D

Time is running out, so get your station ready for Phase 3D. After launch there will be a month or two of study and control efforts before the communications channels are opened for use. This will be a good time to monitor telemetry from the satellite. The 70 cm beacons on 435.450 and 435.850 MHz will be most likely to be used by ground controllers for satellite monitoring. After release, some restrictions will be placed on operation during periods when the ammonia arcjet motor is on, due to its high power consumption and RF noise generation.

Note: If you are not familiar with hamsat communications, you may want to start with the easier satellites, like RS-10, RS-12 and A-O-27.Then progress to the high-orbit world of A-O-10. Check out the entry-level articles presented in the "Hamsats" column during 1996. 73

DXing 10m FM From Perth

The sunspots are rising, so 10m will be coming back.

Graham Rogers VK6RO
22 Grace Street
Ferndale, Western Australia 6148

At the Perth International Airport, Western Australia, sitting in the waiting room of the international arrivals section opposite the customs exit door in April 1993 was an exciting time for me as I was about to welcome Bill G4TQV and his XYL Jean to Australia. Bill and Jean had flown 12,000 miles to visit and this meeting was the culmination of our many contacts on 10m FM since 1988. If it had not been for my keen interest in FM HF DX I would never had met young Bill.

I have had a great time working many UK stations over the years, many of them mobile, using just a few watts from modified UK CB FM rigs. Back in the early 1980s I would hear all these wobbly signals just above 29 MHz on my SSB-CW rig. I was intrigued as to what was going on; then I discovered they were JAs making local contacts.

Not many rigs in those days were fitted with FM on HF. In 1982 I invested in a Kenwood TS660, plugged it into my 2-element 10m quad and called CQ DX on 29.600 MHz. To my great surprise JE6QJV came back to me and we exchanged 5 x 9 reports. I was hooked!

We all know FM is used on 2 meters for local work and here I was talking to Japan on FM. The technical aspects of FM on HF make for rather interesting propagation and signal reception. Phase distortion or the capture effect can make signals hard to copy and stronger signals can completely swamp weaker signals.

I have used as little as one watt and had nice contacts with friends in the UK. An output power of 50 watts seems sufficient for working most DX. On this band the power doesn't seem to make a lot of difference. I've worked many mobile stations around the world who were running 10 watts or so to a modified CB rig.

Lengthy rag chews are not uncommon over great distances. I even worked Bill G4TQV/M through several countries over a 2-hour period as he drove across Europe, with his callsign changing as he crossed borders. Bill surprised me by becoming GM4TQV/M as he entered Scotland on several occasions. Other regulars were Bill GØRUB and Jan PA3FAO. Then there was Roomy VU3RMS, who often surprised me with a booming signal when I thought the band was dead.

There's no shortage of DX. I worked 1SØXV in the Spratley Islands for my 100th country. Some of the rarer stuff I've worked has been A2, A9, BV, BY, CN, CU, EA6, EA9, FT8X, FT8Z, H44, HZ, J2, KX6, SV5. TA, TL8, VQ9, XX9, T30, S21, 5X, Z21, V51, 3B8, 3B9, 3D6, C21, 4S, 5H, 5W, 7Q, 7X, 8Q, 9J, 9M2, 9M8, KH8, 9Q5, 9V, etc. I'm now at 132 worked on 29 FM.

The international calling channel is 29.6, but don't use it for rag chewing, just calling. Hey, don't forget to listen for me on 29.6, or talking away on 29.51.

Repeaters

There are a number of 10m FM repeaters around the world—DU, W, JA, VK. They mostly use 29.6 input and usually output on 29.7. Some use 88.5 Hz or a 1250 Hz tone burst (Ed. note: the Boston repeater inputs on 29.62 and outputs on 29.52). Some repeaters are linked to 2m, so you can find yourself talking with someone using a 2m HT. 73

NEVER SAY DIE

Continued from page 4

are about to spread anthrax all around America, killing millions of people. Aliens will be here in a 100-mile-long spaceship on December 17th. You name it, I get 'em. But, being pragmatic, I sat down and read René's book. He presented one scientific fact after another, undermining my faith in NASA's credibility. It sure seemed like he had made an airtight case for the Apollo missions to all have been a giant hoax.

My next step was to write an editorial about it so others could read René's book. I wanted to see if they could find holes in René's scientific logic. Now, with several hundred *73* readers having read the book, I don't think I've had anyone seriously challenge René's data. Could it be that it's the believers in the moon hoax who are the ignoramuses?

And, as I've reported, I've had letters from several readers who have been involved with either NASA or a NASA supplier, and who also have had their own serious doubts about the moon landings. One chap who helped build the LEM unit said that no one at his company that he knew believed for a minute that the flimsy module they'd made could have possibly made the trip. I got similar letters from hams who'd worked for other suppliers.

I heard about another earlier book which was similar to René's, *We Never Went to the Moon*, by Bill Kaysing. This, too, is self-published, since the publishers he approached with the manuscript were afraid to touch it. Who needs the CIA, DIA, FBI, IRS, NSA, and so on down the alphabet on your case? Plus there are too many dead whistle-blowers when people start to reveal government secrets.

It took me a while to track Bill down and get a copy of his book. It's 8-1/2" x 11" and runs 200 pages. And while Bill makes a few of the same points René does, he mostly has his own set of reasons for doubting the reality of the moon missions. He does a good job of explaining how the whole deal was pulled off, and the secret base in Nevada where the filming was done. He also points out the incredible series of accidents that killed so many astronauts just before the Apollo missions—something that didn't happen before and hasn't happened since. Were they reluctant to go along with the charade?

Then there is the strange death of Tom Baron and his wife. Not long after Tom blew the whistle on the Grissom "accident" his car "stalled" on a railroad crossing and they were killed. Even though the state law requires autopsies in all accidental death cases, his and his wife's bodies were hurriedly cremated. When's the last time your car stalled? And imagine this managing to happen on a railroad crossing just as a train is coming. What are the odds? And what happened to Baron's 500-page report which has now totally disappeared? For that matter, how come NASA's Apollo records, while not classified,

The Whole World—In the Palm of Your Hand!

And you thought 007 had some neat stuff.

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108
dmiller14@juno.com

The government's acronym GPS is for their NAVSTAR GLOBAL POSITIONING SYSTEM constellation of satellites—21 navigational satellites, along with 3 spares, slowly circling the Earth, twice in a 24-hour period. With a hand-held GPS receiver, about the size of a current dual-band amateur HT (and costing roughly the same), you can determine exactly where you are, anywhere in the world.

GPS is fun!

Ham radio operators have always been curious by nature. That's pretty much how the hobby started; curious private citizens picking up the necessary parts and pieces, assembling working transmitting/receiving stations just for the fun of becoming involved in an emerging technology (and that was before anyone knew what "emerging technology" meant!). If you've ever regretted the lack of really new fun things for the ham experimenter to tinker with, take a closer look at GPS and APRS, the Global Positioning System and Amateur/automatic Packet Reporting System. APRS is an already growing branch of GPS that has some fascinating ham radio applications. I'll bet you knew that somehow we hams would be involved; we can't let a curious new technology get away! (For a detailed article on APRS, take a look at the excellent piece written by Bob Bruninga WB4APR in *73 Amateur Radio Today*, December 1996.) I'll try to introduce you, if you haven't already looked into APRS and GPS, but my approach will be a little different. Instead of just briefly mentioning what features are available on a current GPS receiver, I'll try to describe what it's actually like to operate one. Too many articles use terms and descriptions that can only be understood by the actual owners of the equipment being described—but that doesn't help the folks being exposed to the idea and the equipment for the first time.

Why do I need it?

If we hams need to ask, then perhaps we've lost some of that inherent ham curiosity. As a good friend of mine, K9KPM, always says, I suppose I don't really "need" very much of any of the electronic gear that I have, but if I enjoy having it, that's reason enough! Ken's right—what do we really need? Ham radio, and its many-faceted side interests, are interesting in and of themselves; they don't have to be justified. They're usually educational, recreational, sometimes even inspirational, but most often, they're just fun things to do. When it comes to new toys, most of us are just little boys in bigger jeans! For those who don't understand that kind of need, there are lots of other ways for them to fill their time ... anyone for stamp collecting? So if you can assume that mindset while reading this piece, not one centered on absolute need, but rather on learning a new science and perhaps applying it to amateur radio, then you'll understand. This concludes the lecture!

By the way, I can remember Uncle Wayne writing in his editorials about the fun that he had a number of years ago participating in sports car road rallies. Too bad GPS wasn't around back then—I'll bet he wouldn't have asked about a need!

The government's satellite system

The U.S. Department of Defense does have a definite need for accurate navigational positioning information; U.S. troops in all corners of the world must know exactly where they are for strategic and logistical reasons. Army troops, Navy ships, Air Force planes and Marine battalions in the field have a need to know exactly where they are at any given moment in time, so our government committed to a new, highly accurate system for navigation that they termed GPS. Unlike the older ground-based systems of Loran C and Omega, or the peripatetic early Sat-Nav navigational satellites, the NAVSTAR GPS constellation is available 24 hours a day, worldwide, and isn't affected by static, stormy weather or outside radio interference. In all honesty, there can be the occasional ionospheric anomaly that will absorb, scatter or duct even a microwave band signal, but as we hams know, these anomalies are rare. NAVSTAR GPS does operate in the microwave region at 1.575 GHz, using spread-spectrum formatting (see Peter Stark K2OAW's treatment of spread spectrum in *73 Amateur Radio Today*, December 1996). The NAVSTAR satellites are in polar orbits about 10,900 miles up, so very few ground-based interference sources bother it.

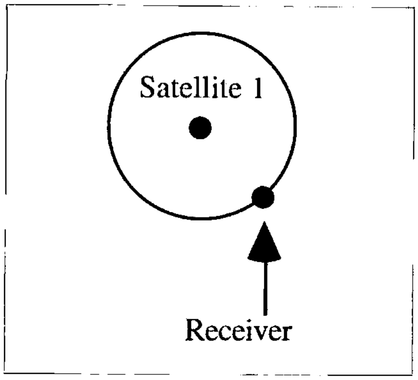

Fig. 1. The signal from one satellite doesn't tell you much – maybe just how far away it is from your position.

The constellation presently consists of 24 satellites and five ground stations at different venues around the globe. Of those 24 NAVSTARS, 21 satellites are kept active; the remaining three are orbiting spares. If one or more of the active satellites becomes "unhealthy," a spare can be moved in to take its place so that the full constellation remains operational. The ground stations monitor the accuracy of the system, and perform adjustments as needed. The government seems fully committed to maintaining the system, which began deployment in 1984 and has been estimated to cost somewhere in the neighborhood of $10 billion; the yearly maintenance alone is some $500 million or more. At those figures, it almost seems unpatriotic not to fully utilize it!

The GPS concept is workable from orbiting satellites because it's possible to receive exact positional data when a ground receiver can lock onto several satellites at the same time; when those satellites are located at different points in the sky; and when the receiver can triangulate a positional fix by receiving accurate geographical and time data from those satellites.

Let's break down those "whens" a little further. When the receiver knows how far away each satellite is, where it is, and what the exact time is, an imaginary circle can be drawn around each satellite being tracked. The receiver is located where those imaginary circles intersect.

Fig. 1 shows where the signal from a single satellite (the circle) would intersect your ground receiver. The signal from just one satellite doesn't tell you very much; perhaps only how far away the satellite is from your location (determined by the time it took for the signal to arrive). If two satellites are being tracked (**Fig. 2**), you can get a little better idea of your position, but since there are two points of intersection, you still can't be sure—it might be either. When three satellites are locked onto, however (**Fig. 3**), even though there are several points of intersection, only one is common to all three—that's your exact position! Having more than three satellites gives even better data.

Each NAVSTAR GPS satellite knows precisely where it is at all times, and where its neighboring satellites are, as well as the exact time, down to atomic accuracy. Knowing these facts, and transmitting them to your GPS receiver down on the ground, will allow the GPS receiver to calculate the time it took for the signal from each satellite to reach the receiver, and thus the distance that the various satellites are from the receiver (remembering that radio waves travel at 300,000 kilometers per second). Because the satellites are at different positions in the sky, a triangulation fix can be made on the location of the receiver, accurate to within 49 feet (15 meters). The actual location of the satellites making the fix can affect the final accuracy of the receiver's position to some degree, but that "final" accuracy can then be further improved. One way is to compare the positional data at two receiving sites that are tracking the same satellites, and then calculate (automatically) a differential that can be applied to the calculated data as a correction factor. That differential (number) can be sent over terrestrial radio and is usually referred to as DGPS (Differential GPS). It can often

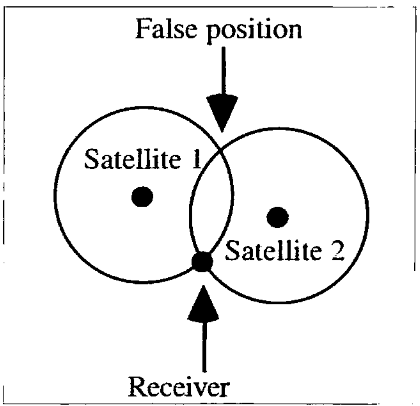

Fig. 2. With two satellites being tracked, since there are two points of intersection, you can get a better idea.

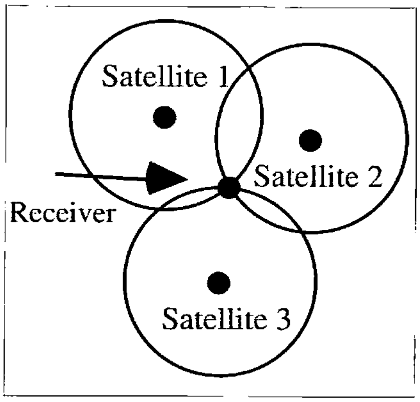

Fig. 3. Only one point of intersection is common to all three—and there you are! More than three satellites can provide even better data.

improve on the final accuracy down to an error of only 16 feet or so. Here's the second part of the equation: The U.S. military deliberately throws some inaccuracy into the GPS system available to civilian users; it's called SA and stands for "Selective Availability." U.S. military users have GPS receivers with a special code that overcomes SA, but civilian units don't, so they're automatically less accurate than their military counterparts. This gives our military a slight advantage over other (enemy) troops that might be bootlegging our satellite positioning information to use against us. The amount of SA inaccuracy introduced is controllable from a ground-based satellite command center that monitors the GPS satellite constellation. During times of troop movements or armed conflict, more SA can be introduced to make it still more difficult for the enemy to profit from our NAVSTAR system. SA inaccuracy is scheduled to be phased out over the next ten years by a law recently signed by the President. Since the SA differential can also be calculated by the means mentioned above (a second receiver site transmitting DGPS information), its value in giving our military personnel an advantage has become somewhat questionable, since the enemy knows how to get around it too, and Congress reasoned that it might as well be phased out so that higher accuracy could be made available to legitimate civilian users. Of course, GPS will also be beneficial to drug runners, smugglers and other nefarious types, but every worthwhile advancement can be abused in the hands of criminals. We can't keep technological advancements away from

the legitimate users just because there is the potential for illegal use—at least that shouldn't be the only consideration.

By the way, the NAVSTAR satellites have also been hardened (as much as is currently possible) to damage from enemy ground-based laser and particle beam attack as well as command control interception that could result in erroneous readings being transmitted from the constellation. They're also EMP (ElectroMagnetic Pulse) hardened and are designed to degrade gracefully, even if ground communication with them is lost. Aerospace design teams have to think of everything these days. The time delay in launching a replacement satellite from the ground is estimated as not exceeding two months, if and when that should prove necessary. Satellites don't last forever; high energy radiation particles from outer space, damage from small meteorites and other space debris and realistic design life of batteries and solar panels all take their toll on even the best satellite hardware.

Uses

The NAVSTAR GPS concept has tremendous potential for the recreational boater, private pilot, Civil Air Patrol volunteer, hiker, backpack camper, explorer, fisherman, climber ... and Uncle Wayne's road rally team! Anyone who strays from home can appreciate the hand-held portable GPS, just as hand-held portable transceivers are commonplace today. And of course we can't overlook the potential commercial users—commercial airliners, passenger and cargo ships, railway trains, over-the-road trucking, delivery services, etc., can all benefit from reliable positional information, and NAVSTAR GPS is it!

Then there's that APRS aspect mentioned earlier; it's a fairly recent innovation in the ham radio community, utilizing current GPS technology. It includes automatically generating packets containing exact positional data from both fixed and mobile stations. That information can then be combined with a normal amateur packet TNC, and transmitted and displayed on a map on everyone's packet computer screen. That's why many of the newer packet and multimode TNCs routinely include GPS capability within their TNC firmware these days. It's an amateur radio innovation (thanks to Bob Bruninga) that is just beginning to be explored.

But what advantage is there in having that positional information? For search and rescue efforts, parade or marathon coordination and safety watch, repeater jammer tracking, neighborhood watch patrol activities, simulated emergency tests, storm and flood assessment and assistance, recreational fox hunting and other amateur radio field activities, GPS offers the same advantages that it does to the military, recreational and commercial users: obtaining and relaying accurate positional data on and to the participating stations. If we still have that ham spirit of discovery and innovation, then it won't be long before even more innovational uses for GPS will emerge within our hobby—and *73* will publish them as they're presented.

So what's out there now?

As to what you can expect to buy right now, I'll use the features of my own (a Garmin GPS 45) in the examples, not because I'm trying to convince anyone to buy the same unit, but because it's the one I'm most familiar with. Other brands and models will have similar operating modes and features, but of course the details will vary.

I thought that my instruction manual was lacking somewhat in its guidance for beginners, especially for something as new and innovative as GPS. I would have preferred that the manufacturer had been more informative in the operator's manual, but there is an optional, well-produced instructional videotape available. The manual assumes that the operator is already familiar with the basics of navigation, waypoints and route planning. For those who aren't, a supplemental book on general navigating techniques from your local library may be worth reading first. I've always felt that tech-manual writers should make sure that they're doing the best job that they can in clarifying all of the questions the beginner might ask. I think the practical way to do this is to test the product, and the manual, by giving units to a few beginners for a week or so, along with the preliminary manual, and asking the beginners to keep accurate notes on the problem areas. A tech writer who's intimately familiar with a unit can't write a basic enough manual, one that's

completely understandable to the beginner. We see this all the time with complex ham gear manuals; not enough forethought is given to explanations that require more detail or practical examples. With modern microprocessor-based equipment, usually with multiple-function keys, a thorough manual is an absolute must!

Some initial details

The first thing you'll notice about GPS receivers: They're amazingly compact, about the size of a current dual-band talkie (my own is just 6 1/4" high by 2" wide by 1 1/4" deep). It's incredible that you can hold a true satellite tracking receiver in the palm of your hand—no dishes, no az-el steering needed. Mine operates from four internal AA batteries that will power it for 10 to 20 hours depending upon the mode chosen (normal or battery saver mode). It has a small detachable antenna (with a BNC connector on it so that an external antenna can be used) and a built-in 4-pin male socket on the back of the unit for inputting outside power (five to 40 volts DC) and ground. There's also a pin for data input and one for data output, for interfacing with a computer or to an external differential or beacon receiver. There are (or soon will be) computer-generated maps of various locations that will allow you to plot exactly where you are on a moving map of your area (or a strange area) so that, with a laptop or notebook computer, and your GPS, you'll really have to work at getting lost! All of these amenities have a price, of course, but they'll probably be within everyone's reach over the next few years if the past is any indication of the future (look at how computer prices have plummeted over the years).

For the boater, camper or hiker, many GPS receiver models are considered waterproof, often being pressurized from within, using dry nitrogen to prevent the infiltration of outside air or water. Mine is, since it was designed for the marine environment, plus it weighs a mere 10 ounces with the four AA batteries installed.

Operation

Here's the good stuff! When a GPS receiver is first powered on (or when all of its memories have been erased), it will take 7 1/2 to 15 minutes to acquire all of the satellites that it can, storing them in an almanac in its memory, and displaying its new home latitude and longitude. This auto-locate initialization is good for up to about 300 miles from home base even if the receiver is off. If you travel farther than that with the receiver off, you'll have to let it auto-locate again or you can enter the new rough latitude/longitude data manually. If you travel with the receiver turned on, or turn it on every now and then, it will re-locate itself as it goes along.

While it's auto-locating, my unit shows a nice graphical view of the sky (**Photo** A), plotting up to 8 NAVSTAR satellites on a sky map; the satellites are graphically depicted as being either on the horizon, at 45 degrees up from the horizon or overhead. The display indicates the satellite's ID number (each satellite has its own identification number), along with a relative signal strength bar for each of the satellites being tracked. This allows the user to move somewhat in various directions, or to re-orient the side-mounted antenna, to achieve the best signal reception from the constellation of satellites in view.

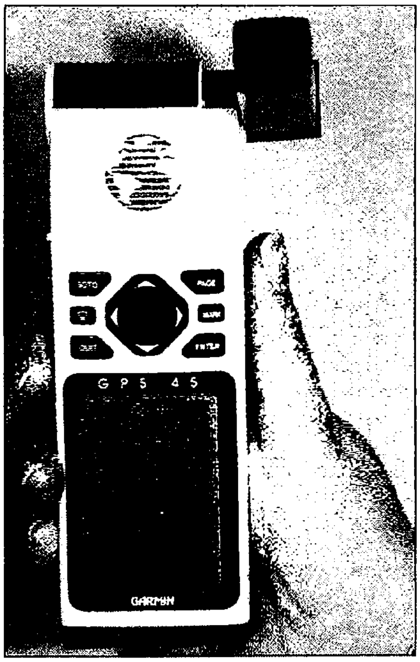

Photo A. Satellites are graphically depicted as being either on the horizon, at 45 degrees up from the horizon or overhead. The display also indicates the satellite's ID number, along with a relative signal strength bar for each of the satellites being tracked.

At least three satellites are needed to obtain a fix on your latitude and longitude; a fourth is required to give your altitude above sea-level data (providing that the unit has that 3-dimensional capability). The more satellites you can acquire at any given time, the better the positional and altitude data will be, because, again, the triangulation will be done with better geometry. I've found that it's not unusual to get good signal strength readings from six, seven or even all eight satellites in reasonably open areas, and at certain times of the day, remembering that 1.575 GHz radio waves are fairly easily absorbed or scattered by ground-based obstacles.

Once the auto-locate initialization stage is finished, and the receiver is satisfied with the data from the satellites that it can see, the page automatically changes and a moving compass dial is displayed (showing your cardinal heading anytime you're in motion; walking is good enough). It also shows a digital readout of your true bearing (a three-digit numerical display of the linear compass dial); it shows your speed of movement when in motion, and of course your latitude and longitude, out to three places, in seconds. It even tells you the accuracy of the latitude and longitude measurement as plus or minus so many feet. It automatically indicates if it's operating in the two-dimensional or three-dimensional mode and your altitude in feet above sea level when it's in the 3-D mode (with a plus or minus altitude error factor, in feet, also displayed). The exact time of day in 24-hour UTC time is displayed, or the time can be read in local time (that is, so many hours differential from UTC). Finally, the condition of the internal batteries is shown on a nice bar-graph gauge ranging from full to empty.

Stepping forward to another page, many GPS receivers will automatically map your path of travel, whether on foot or in a moving vehicle. This moving map shows every twist and turn that you might make along the way (see **Photo B**). The map (actually it's more of a where-I've-been course plot), looks something like a doodle you might have drawn on an Etch-A-Sketch™—at least that's what it reminds me of. But it's a lot more powerful than my Etch-A-Sketch ever was! When you arrive at your destination, you can follow the doodle and retrace your exact path back home. Rather than following the exact course home, you can opt to take the shortest route back instead (if you're in open country, on the open water or in the air). The map will show you the heading for that shortest course and it will display your return trip on the same map page, so that you can see immediately if you happen to stray off your mark. You can zoom in and zoom out (in 12 different steps) on the map to see every twist and turn, and you can pan across to see where various zigzags were necessary. **Photo B** shows a little doodle-map I made coming home from the store one day. It's zoomed to the 1.0 mile scale and you can see the little zigzags needed to get to my home. They're even more pronounced when zoomed into the 0.2 mile scale. My home QTH is shown in the center. The scale in miles is displayed at the top and changes as you zoom in and out. You can pan across the map to measure the exact distance from one point to another or to find those little details mentioned when you're zoomed all the way in. The map page also shows the bearing you should be taking to get back home on the return trip, the one you're actually on, the distance in miles to your destination and the speed at which you're currently moving. Everything you might possibly want to know—except perhaps where the radar speed traps are (there's other gear for that!). Incidentally, I *do* know the way back home from the store on my own, but it's a whole lot more fun this way.

"This gives our military an advantage over enemy troops that might be bootlegging our satellite positioning information to use against us."

If you decide to take the exact (retrace) course back to home base, as you might when hiking overland with natural obstacles to maneuver around, you can switch to a roadway style of display. As you can see in **Photo C**, the display looks something like a highway drawn in a perspective view, with a center line right down the middle. To retrace your exact original course, simply keep the little cursor arrow right on the center line of the roadway; you'll end up exactly where you started. There's even a finish line that appears across the roadway in case you've forgotten what home looks like.

I've mentioned only a very few of the navigational features found in a modern GPS receiver. There are a number of others. As the menu page shows in **Photo D**, you can set and store waypoints and routes, naming each one for easy recall. A waypoint is a specific location that you would like to head toward and at which something will occur. A route is a number of waypoints strung together. Putting it in understandable terms, when you drive to work each morning, you probably follow pretty much the same route. Beginning from home, you might head down Street A to Street B, making a left turn on Street B. That intersection is a waypoint. You then take Street B to Street C and turn right; that's another waypoint, a point along the way where something happens. Stringing all the waypoints in series is your route. On the open water, in the air or out in the wilderness, where streets and intersections don't exist, longitudinal and latitudinal waypoints become very important when you can't navigate by visual landmarks. They provide points of significance, where a turn or course

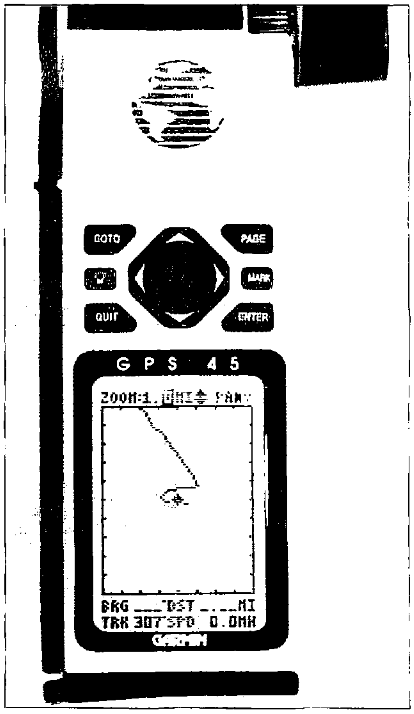

Photo B. The "Map Page" capabilities of the unit with the "moving" map readout of my trip home from the store.

change should occur, perhaps to avoid some obstacle (such as a reef while sailing). It's vital for the navigator to know when he or she has reached a waypoint, and a GPS receiver will tell you that with class. Mine will store 250 waypoints, each with its own unique name (such as HOME, FUEL, REEF, etc.). It handles 20 routes (collections of waypoints) which are reversible. If a storm suddenly comes up, there's a "nearest waypoints" page that can be called up, providing you with and guiding you to the nearest of nine safe haven waypoints (providing you've stored them in memory). There's a CDI (Course Deviation Indicator) display, an ETE (Estimated Time Enroute) display and an ETA (Estimated Time of Arrival) display at your disposal when you need them. There's a sunrise/sunset indicator that will even tell you the time of these events at the destination you're navigating toward. There are also internal messages that may be displayed from time to time: "Poor GPS Coverage" or "Accuracy Has Been Degraded" are displayed when satellite coverage is poor or non-existent.

In general, GPS receivers are meant to be used out in the open. If the 1.575 GHz signals from the satellites are blocked by buildings, mountains or even dense forest, reception will be degraded. It's still amazing that sometimes I can actually receive three or four satellites at our kitchen table—because of a large picture window facing due north.

All of these GPS functions—predetermined waypoint plotting and storage, routing information, track logs, etc., can vary from one unit to another. Some GPS receivers are aimed at certain outdoor activities or sports, such as boating. Those functions are determined by the firmware chosen by the manufacturer for a particular GPS unit, so, depending upon your own interests, you can often find a model aimed more at your own outdoor activity (I've always loved sailing). However, even a GPS aimed at the nautical crowd can be used for any general purpose navigation exercise—even just a Sunday afternoon walk through the woods. Anyone want to start an orienteering club?

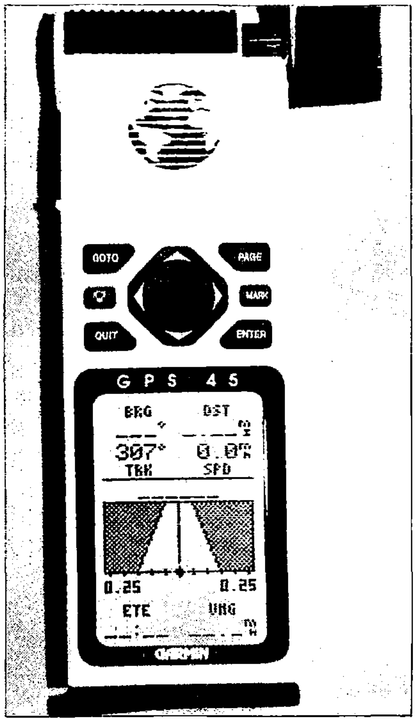

Photo C. The "Go-To-Waypoint Page" helps you to retrace your route home or to find a specific stored waypoint.

There's also a menu screen that allows the user to call up other submenus to assign the names to waypoints, enable or disable some of the functions, clear memories, define the functions (such as reading out in nautical miles as opposed to statute miles) and to access stored tracking information. You can keep a stored record of your excursions so that you can call on them in the future if you'd like to follow the exact same route, or just to revisit some enjoyable spot.

Mine even has what's called a MOB (Man OverBoard) function, which will allow you to zip back to a particular geographical spot in an emergency...say if your mother-in-law happens to fall over the transom of the boat and you hadn't noticed. Of course, it's entirely up to you if you choose to enable that MOB option or not!

A practical example

A GPS receiver in the mobile can come in very handy. My wife and I took a long-weekend motor trip into the hinterlands of Wisconsin shortly after I bought mine and installed the optional dashboard mount for the GPS-45 in our car.

Photo D. The "Menu Page" capabilities of the Garmin GPS-45 NAVSTAR satellite Global Positioning System receiver.

Even though Sue has her General Class ham license, I have the feeling that she doesn't always see the complete sanity in every electronic purchase I make. She seemed to appreciate (on the surface) the practicality of our GPS receiver, but it wasn't until we started taking some really off-the-beaten-path scenic roads that she commented, without any prompting from me, that having a GPS onboard was a nice idea. We had no fear of getting lost down those twisting, turning country roads because we knew that we could always find our way back if we ended up hopelessly lost. We saw some mighty pretty fall colors too! In fact, we spent most of the trip on those scenic back roads, and we'll do it again! The map that we had wasn't nearly detailed enough, so we followed our noses and ended up driving around one city in a large circle. We followed a route bisecting the circle and ended up where we wanted to be originally—without going all around the circle again—a first for us!

I found that just mounting the GPS up on the dash, with the windshield curvature overhead and around the sides, gave us reliable satellite coverage. The 1,100 mAh nickel metal hydride AA cells that I'm using in the GPS-45 will power it for a full day's driving on the battery-saver mode and I simply recharged them overnight in our lodgings. It's nice to have an accurate compass onboard too (one that doesn't dance around), and I discovered that the car's speedometer is actually three miles per hour slower than true. But just having an accurate map of where we had been, and knowing that we could always get back again, was very comforting, and as Sue put it, a nice idea. In unfamiliar territory, it only takes one wrong turn to become disoriented; but with your GPS receiver, you can find your way back easily.

As an aside, I did notice some RFI in our 2-meter mobile transceiver, on certain frequencies, attributable to the GPS receiver's oscillators. The solution was to avoid those frequencies, but it was somewhat surprising. I've not tried to work out another solution yet; the problem isn't serious for us since it doesn't affect the channels we're most interested in monitoring. There may be conflicts like this on other bands as well; I've not checked them, but don't be too surprised if you find some birdies somewhere.

Other interesting asides

GPS technology has a number of diverse potential uses for the future. It can be used for tracking endangered species, with exact positional data always available on the monitored animals, as well as auto-mapping of a particular animal's recent roam-area. GPS has seen duty on high altitude balloon flights investigating the much publicized ozone layer depletion studies and it was used to record the undersea resting position of the famed passenger ship *Titanic*. It can be used in forestry and geological survey studies, accurately mapping the boundaries of areas of natural resources as well as in locating and documenting small villages and remote population concentrations in obscure parts of the world. Since one of the side benefits of GPS is high accuracy time keeping, anyone who needs that advantage (radio amateurs included) can benefit from this important aspect of the orbiting satellite PVT (Position-Velocity-Time) technology. Mapping flood- or hurricane-ravaged areas anywhere in the world by air and helping to deploy and direct firefighters to forest fires also requires accurate positional data, in the air and on the ground; GPS answers those needs. There's progress being made to use GPS as an aid to the blind, which is yet another reason for doing away with the intentional inaccuracy of SA (discussed earlier). Coupled with a voice synthesizer, the waypoint and routing features of a GPS receiver can potentially be used to prompt blind people to reach a predetermined goal.

The Russians are coming!

Orbital placement of a second constellation of global positioning satellites has been underway for several years now, initiated by Russia. It was begun before the breakup of the Soviet Union and goes under the name GLONASS. When fully operational, GLONASS also promises to provide position, velocity and time information to users worldwide (most current GPS receivers will probably not be usable with the Russian system, though the frequencies used are relatively close—GLONASS is said to be just above 1.6 GHz).

As you can see, the average GPS receiver is versatile, affordable, and works by reading the data from orbiting satellites 10,900 miles or more away ... all in the palm of your hand. To me, that's pretty exciting. What do *you* think?

Communications & Live ATV Via Outer Space

Some real-life use of the ham satellites.

Farrell Winder W8ZCF

Waldron IN 46182
E-mail: w9ntpdon@ind.tds.net

During the 1996 Dayton HamVention, a short movie was discovered running at the AMSAT booth. This movie showed two amateur stations involved in a Q5 QSO utilizing the AO-27 satellite.

Several months earlier, W8ZCF and his son, KB8VCO, had been trying to come up with a plan for communicating while KB8VCO was on vacation with his family in Juarez, Mexico and El Paso, Texas. They considered several of the HF bands, but decided that unless enough power and suitable antennas could be set up by KB8VCO on a portable basis, that such an arrangement didn't seem feasible, at least on a consistent basis.

Photo A. KB8VCO's equipment for AO-27 voice contact (photo by Vicky Winder).

The AMSAT movie raised the possibility of using AO-27 for the communications link. Tests were made just before the trip to Juarez; KB8VCO used a Yaesu FT 530 dual-band HT which provided about two watts output on two meters, along with 70 cm reception. The antenna was a Cushcraft A270-6S, consisting of a pair of three element yagis on a single mast for transmitting on the two meter uplink frequency and receiving on the 70 cm downlink frequency. It was used as a handheld antenna and manually pointed towards the satellite. **Photos A** and **B** show KB8VCO's setup. A tracking program was used for initial antenna orientation with signal strength indication from the satellite to maintain tracking.

"Those pictures were sent over 2,000 miles round trip using 1/2 watt on 70cm!"

Upon arrival in Juarez, and for a period of more than two weeks, contacts were made on a daily basis from the Juarez/El Paso area to and from Cincinnati, Ohio. During the return trip, contacts were continued from Texas and Arkansas. Those contacts were so successful that an idea emerged for an experiment while W9NTP and W8ZCF were in contact during regular early-morning ATV exchanges between Waldron, Indiana and Cincinnati, Ohio. The idea was to try sending a live picture via AO-27.

Initial experiments were encouraging. On the third attempt, complete pictures were sent and received by both W9NTP and W8ZCF. Photographs of these pictures are shown in **Photo C** and **Photo D**—remarkable, considering the very low output power of the AO-27 which is only 1/2 watt on 70 cm! This microsat satellite is a cube-shaped package approximately 5.9 inches on a side and in a nearly circular polar orbit at about 500 miles above the Earth. The actual distance covered in transmission to and from the satellite to create these pictures was over 2,000 miles, round trip!

The uplink frequency for AO-27 is 145.850 MHz and the downlink is 436.800 MHz. Approximately 20 kHz of Doppler was observed over the longest AOS to LOS footprints. W9NTP's setup used an OSCAR circular polarized antenna for 2 meters. A

Photo B. KB8VCO tracking AO-27 (photo by W8ZCF).

vertically polarized FO-22 (22 element yagi) antenna, (with az-el rotators) feeding a KP-1 preamp into an ICOM R7000, was used for receiving 70 cm. A Robot 1200C Color TV Scan Converter was used to process the video sent to and from W8ZCF. A Yaesu FT 736 was used to transmit video on two meters to the satellite.

W8ZCF's setup used the basic antenna setup used regularly every morning for "earthbound" ATV contacts. This consists of a Cushcraft 13B2 (13 element) yagi, vertically polarized antenna on two meters and a Rutland FO 22 (22 element) horizontally polarized yagi for 70 cm. The FO 22 fed a KP-1 preamp to an FT 736R for 70 cm receiving. A Tasco TSC-70U SSTV Scan Converter was used to process the sending and receiving of pictures to and from W9NTP. The transmission mode used by both stations was Robot 36 Color.

Over the course of this experiment, several local stations became interested and engaged in voice contacts on AO-27. Dick Goode W8RVH, in New Carlisle, Ohio, did an analysis with a 7 element home-brew yagi for the 70 cm signal from the satellite. He discovered that the satellite transmitting antenna consistently enters the descending pass with vertical polarization and rotates to a nearly horizontal polarization during the completion of the pass. W8ZCF's FO 22 horizontally polarized antenna without an elevation rotor therefore gave best performance at low (under 5°) elevations which occurred during the latter part of the westernmost passes. Signal strength on the lower part of these western passes often yielded readings of S9 +10 to 20 dB.

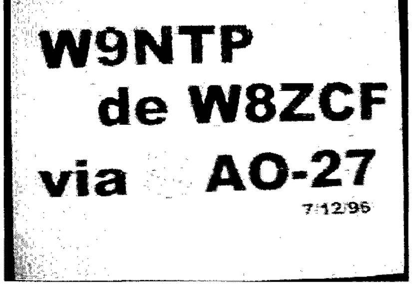

Photo C. Picture received by W9NTP using a Robot 1200C Converter (Mode: Robot 36 Color).

"This satellite provides pleasure and experimentation to many."

W8ZCF used the STSORBIT PLUS Tracking Software Program written by David Ransom, Rancho Palos Verdes, CA. The initial position of the satellite during the start of the video transmission of the picture to W9NTP is shown in Photo E (the STSORBIT graphic presentation). W9NTP used the Instant Track satellite tracking program.

The picture received by W9NTP is regarded as almost a "perfect picture." A partial single horizontal noise line appeared in the original picture just above the W9 portion of the call letters. This was corrected by using the "Fix Glitch" feature of the HIRES-70 program developed by Tom Jenkins N9AMR of Indianapolis for use with the TASCO TSC-70 Scan Converter. The picture (**Photo C**) received originally by W9NTP was later retransmitted to W8ZCF from Waldron, Indiana and photographed from a 14-inch TV Screen using a Pentax ME Super Camera with 1/4 sec. exposure. **Photo D**, received direct by W8ZCF, was photographed using the same TV/camera setup.

Photo D. W9NTP's picture as received by W8ZCF using a TASCO TSC-70 (Mode: Robot 36 Color).

This project proved to be challenging, fun and rewarding to the parties involved. Several bystanders also followed this experiment—and as a result, a number of new satellite communicators have emerged. All of these operators may now be better prepared to utilize the future multimode satellites, such as Phase 3D, that are in progress.

Thanks go to the many innovative engineering designers and developers who have made the AO-27 satellite with its performance capabilities possible. Obviously, this satellite provides a great deal of pleasure and experimentation to many amateur radio operators. 73

Satellite Tracking With Style

Nova for Windows©

Andrew Skattebo KAØSNL
P.O. Box 241
Knoxville IL 61448-0241

Every once in a while a piece of software comes along that makes me glad I own a computer, or might prompt me to buy one if I didn't. Nova for Windows© is just such a program. This full-featured satellite tracking program from Northern Lights Software is not only useful to diehard satellite enthusiasts and EME operators, but is also a fantastic educational tool for anyone interested in satellites and space activities in general.

This program, written by Dr. Michael Owen W9IP and Dr. C.J. Knickerbocker, is a giant leap forward in quality and capability over most other current Windows tracking programs. The fact that you've got something new and different is boldly obvious as you look at the opening screen. Displayed is a gorgeous full-color map of the Earth with a constellation of satellites whizzing around it. This color map is different from other, cartoonish displays, since it is actually a composite satellite photograph of Earth, showing the varied terrain—including mountains, rivers, deserts and even snow in the extreme northern and southern hemispheres.

This display is also customizable to your heart's content. You may choose between a flat map of the Earth with the satellite footprints projected on it, or a 3D space view with footprints. There is an *incredible* 3D view with the orbits for each satellite shown and labeled. This view is a great learning tool for beginning satellite operators or for student education. It allows you to visualize the satellite in orbit and helps make sense out of those abstract numbers (Keplerian elements) used for satellite tracking.

In addition to the basic screens there are a couple of unique views that are harder to visualize until you actually use the program. First is the radar view which gives you a radar screen image with satellites plotted in an azimuth-and-elevation display, showing their paths across the sky from your location. Also available is the sky view, mainly of interest to moonbounce operators, which plots a selected satellite (or the moon) on a map of the sky showing the natural background noise sources such as the center of our galaxy. Not only can Nova for Windows track satellites but also the sun, moon, planets and a handful of other celestial bodies. The overwhelming thing about all of these views is that you can have them onscreen one at a time, or in any combination, even all at once. The program has no limit to the number of satellites you can track or display views you can have running simultaneously. You can track to the limits of your computer capability and display readability.

Besides the flashy new displays and functions, the program has a solid base of features, as we've come to expect from satellite software. A printed table of upcoming passes for a satellite, two-observer mutual windows, squint angle information and two-satellite mutual visibility are only some of the basic features. A quick visibility check feature allows you to see at a glance which satellites are above your horizon at the present time. Of course, automatic antenna tracking is also supported for those of you using the Kansas City Tracker, SASI Sat-Tracker or AEA's ST-1 rotor control interfaces. These are just a few of the functions available—there are simply too many to list!

Even though there are dozens of features and new capabilities, the program's operation is pretty straightforward. The software takes advantage of the standard Windows user interface so it has a familiar look and feel. Some users may wish for a user's manual or more extensive on-line help files, since there is no manual and help files are absent from some screens. However, a little time spent exploring the program will have you operating comfortably in a short

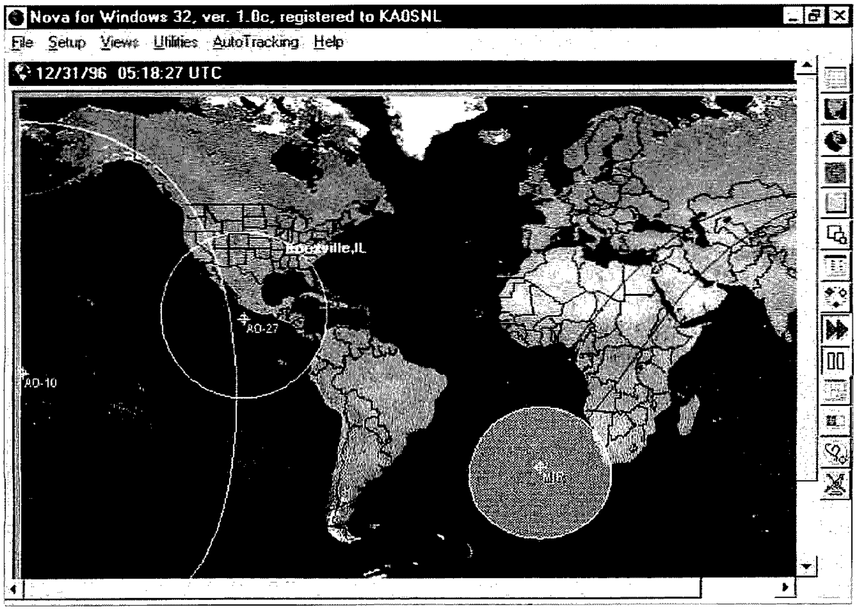

Fig. 1. Map from Nova showing footprints of AO-10, AO-27, and Mir.

time. Many of the commonly used features are available on a toolbar. This toolbar allows changing displays, and accessing some of the setup options from a simple point-and-click interface. Functions such as modifying the observer database, and updating the satellite element files, that are not reachable from the toolbar, are accessed from a menu at the top of the screen or by right-clicking on a particular item.

Nova for Windows allows most users to get up and running quickly. There are only a few things to accomplish to make the program immediately useful, and a quick tip sheet (included with the program) provides basic information to get you started. After completing installation, make sure your station location is in the observer list. Go to the menu at the top of the screen, click on "setup," then "observers." Find your city from the right side main database and drag it to the left observer database. If your city is not listed you must manually enter the coordinates in the lower left panel, enter the location name and save it as a new observer site.

Also, to ensure that you have up-to-date Keplerian elements you will need to update that file with the most current set. Get your keps from your usual source and save the text file in the Data folder of Nova's directory. To update Nova go to the menu at the top of the screen. Click "setup," then "satellites." This brings you to the satellite editor screen. Now click "update," and find the file you want to use for the update. Select "open" and your file is automatically updated. Simple as that.

To configure your tracking screen or create additional views, you can right-click on the map screen or use the button on the toolbar. In either case select "configure current view"; this takes you to the individual view configuration screen. Simply drag and drop observers and satellites from the respective lists. Select a map display option and right-click to customize that map to your needs. When you're done click on the new button and type in a name for this view. Select "OK" and you're set. You can create as many configurations as you like for different situations. For instance, I have one for the microsats, one for high-orbit birds and another with the shuttle and *Mir* only, for use during Sarex missions.

Nova for Windows is available in both 16-bit Windows and 32-bit Win 95 versions. The programs are nearly identical. The 32-bit version for Windows 95 does take advantage of Win 95's multithreading and multitasking features for smoother operation when autotracking. Additionally, new add-ons such as Nova FTP and Nova GPS are designed to use the 32-bit Win 95 version. Nova FTP automates the process of updating

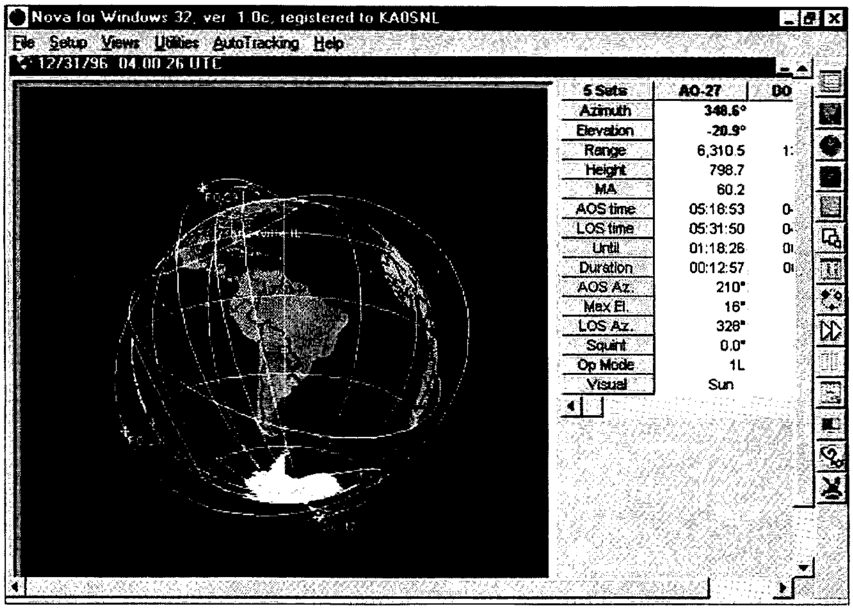

Fig. 2. Space view from Nova showing multiple satellites and their orbits.

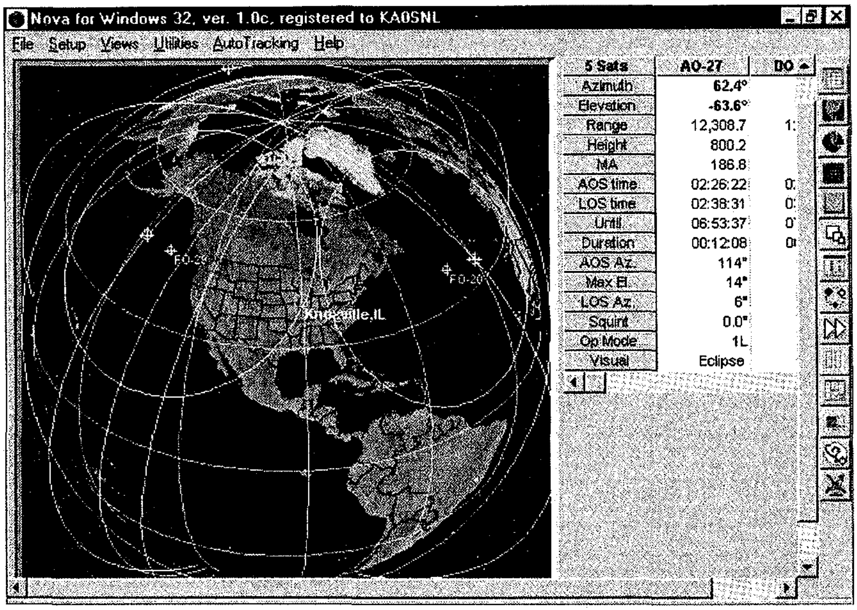

Fig. 3. Nova screen capture showing the space with orbit view and satelite footprints.

Keplerian elements and Nova GPS reads information from a portable GPS receiver and updates station time and location information. Contact Northern Lights or visit the Web site for the latest information. I have both versions of the program, running on a 120 MHz Pentium™ with 16 MB of RAM and the Novawin folder occupies approximately 13 MB of space on my hard drive. However, the minimum system requirements call for at least a 386 with coprocessor, 10 MB of hard disk space and a VGA display with 256 colors or more.

I still sit amazed as I watch the microsat satellites marching in order, coming up over the pole in almost single file, their orbits displayed along with their footprints, all being tracked at once, in real-time. I have seen nothing like it before and friends, even non-hams are enthralled at the display quality. It has become a favorite demo to show off the computer to visitors and I can see its usefulness in education as well. This program is a must-have for anyone interested in satellites, moonbounce and other space-related activities.

Nova for Windows is available from AMSAT for a donation of $50 for members and $60 for non-members. Currently only the 16-bit version is available through AMSAT but you can easily upgrade by going to the Nova Web site and downloading the 32-bit upgrade. A portion of the proceeds will go to benefit the amateur space program, so your money does double duty. You get a great piece of software and the amateur space program gets your support.

To order, contact:
AMSAT
850 Sligo Avenue Suite 600
Silver Spring MD 20910
Ph. 301-589-6062

For more information, contact:

A 500-Foot Antenna?

Going to new heights in Maryland.

Joe Nunemaker KD3VR
9303 Calanda Street
Lanham MD 20706

John asked, "What kind of signal would you get with a 500-foot antenna?"

"A great one," I said.

"Hmmm," he said, pondering the idea. "How would you support a 500-foot antenna?"

I considered for a moment. "A balloon would do nicely," I said.

"Do you think a kite could take up 500 feet of wire?" he asked.

John Williams N5SJZ called me a few days later with some exciting information. He had visited a kite store where he had researched a number of kites and their flying abilities. I drove to his home to see his space-age kite and listen to him describe its performance characteristics. The kite was made of rip-stop nylon, shaped in a combination delta and box form. This type of kite is specifically designed for stability and strong lifting ability in high winds. I agreed we should give it a shot, so we made plans to try it out as soon as possible.

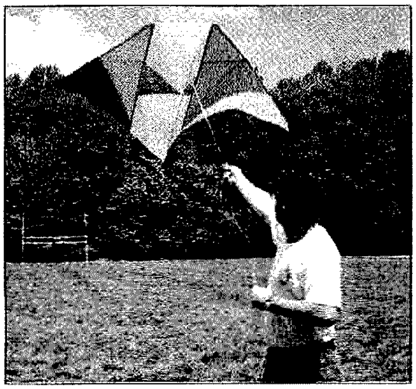

Photo A. John Williams N5SJZ launching the 500-foot antenna.

We put together a nice portable station and waited for a good day. Our station consisted of my TS440S, an antenna tuner designed to load a longwire, a four-foot copper ground stake, an antenna insulator, a fishing swivel to prevent twists in the wire, and assorted hardware to connect everything together.

"Do you think a kite could take up 500 feet of wire?"

We looked at various types of wire. We thought 500 feet of copper wire (even 20 gauge) would be too heavy, so we looked around to see what else was available. Aluminum electric fence wire was light, cheap, and readily available in 500-foot rolls. A good solution.

During the course of our on-the-air discussions we were joined by Glenn Garnes N3UCE, who wanted to participate in our adventure—and let's not forget John's wife, Debby N5SKA.

Photo B. Glenn Garnes N3UCE, Joe Nunemaker KD3VR (back), Debbie Williams N5SKA, John Williams N5SJZ (front), working the pileups.

Did it work?

It was not long before we had a perfect weekend afternoon—sunny, windy and warm. What more could we ask for?

We found a great location for our adventure—the US Naval Academy in Annapolis. The Academy has a large field area right next to Chesapeake Bay, with no power lines anywhere around. We set up the kite in a few minutes and it hauled our antenna up without a hitch. The signals were so strong we had to use the radio's attenuator.

> ***"The signals were so strong we had to use the radio's attenuator."***

Our CQs resulted in some nice contacts, and within an hour we had a waiting list. In order for everyone to operate on HF, I was the control operator and we worked under my call for the day. Working 80 meters. we covered mainly the eastern half of the U.S., along with several stations from Canada. Signal reports were 5/7 or above. The antenna and its mount were the topic of the day!

It was an exciting day and we plan to do it again soon. After our outing Glenn N3UCE visited a kite store and bought a 14-foot kite that I'll bet could lift a small child. We're planning to send up 1,000 feet of antenna wire with that kite. Listen up for us. Better yet, buy a kite and join the fun! 73s.

Photo C. The rig and antenna tuner. Yep, that's all it took to have a fantastic time—plus the kite, 500 feet of wire, and a breeze.

KC2 Multi-Function Transceiver Accessory

The tiny kit that does it all!

Robert S. Capon W3DX
(formerly WA3ULH)
107 Cavalier Drive
Charlottesville VA 22901

If membership in the three-year-old Northern California QRP Club (NorCal) can be used as an indicator, interest in QRP kit-building is making a strong comeback. This year, NorCal membership quietly zoomed past 2,000 members.

One of the key reasons for this enthusiasm in NorCal is the series of innovative QRP kits designed by Wayne Burdick N6KR, made available to club members by NorCal and to the general public by Wilderness Radio. These kits have included the NorCal 40, a 40-meter transceiver that draws only 17 mA, and the Sierra, a multi-band QRP transceiver with band modules, featured on the cover of the *1996 ARRL Handbook*.

Wayne's latest kit is the KC2, a unique multi-function transceiver accessory. The KC2 combines a memory keyer, 4-digit LCD frequency counter, bar-graph S-meter, and a digital wattmeter in a package that draws a meager 7 mA and measures 1.1" x 2.9" x 0.8". This combination makes the KC2 an ideal accessory for QRP transceivers.

Three KC2 innovations

The KC2 employs a number of innovations to address the common problems traditionally associated with QRP frequency counters: size, current consumption, and noise.

To achieve its small size, the KC2 uses two printed circuit boards that are stacked like a sandwich, and held together by nylon nuts, bolts and spacers. Further, the two largest components are mounted piggyback.

To reduce current consumption, N6KR employs carefully chosen power efficient CMOS components, and uses an LCD display. The KC2's current consumption of only 7 mA compares to 100-200 mA for comparable frequency counters. As a result, my Sierra QRP transceiver draws a total of only 40 mA, including the KC2 frequency counter and keyer!

Perhaps the most novel innovation employed within the KC2 is in the area of noise reduction. Most frequency counters must be mounted in an external enclosure because of microprocessor noise leaking into the radio's receiver. N6KR discovered that he could eliminate noise by running the KC2's 4-MHz microprocessor at a sluggish 100 kHz. As a result, the KC2 can be mounted inside a transceiver without the need for any special shielding.

> ***"My Sierra QRP transceiver draws a total of only 40 mA, including the KC2 frequency counter and keyer!"***

Frequency counter

The KC2 display default is the frequency counter. The counter is a four-digit LCD display with 0.1-kHz resolution. The display numerals are approximately 0.35-inch in height. A hysteresis technique is used to eliminate flicker of the last digit.

The counter will read VFOs in the range of 300 kHz to 6,400 MHz, making the KC2 usable for most QRP rigs. But be sure to check the user's guide on your QRP rig to make sure that the VFO falls within this range.

The KC2 features four programmable offsets stored in nonvolatile memory to work with multiband, multi-offset radios. This should prove to be overkill for most QRP rigs. The Sierra eight band radio has the most complex assortment of VFO offsets (three) of any rig in my collection. The Oak Hills OHR-400 four-band rig uses the same offset for all four bands.

Programming the KC2 is a snap! To program it, you set your rig to a convenient frequency as measured by your main station transceiver, scroll the KC2 display to match the frequency, and exit set-up mode to accept the frequency. That's it.

Keyer

The KC2 is a respectable memory keyer, but lacks the dazzling array of keying features (like automatic sequencing of serial numbers) found in the CMOS Logikeyer III, which is still my favorite high performance memory keyer.

However, the KC2 does include a 50-character keyer memory with a useful repeat word function and multiple memory partitions. Keyer memories are stored in nonvolatile memory; however, memories do not have separate buttons for each partition. For example, to access memory partition number three, the user presses the keyer button three times.

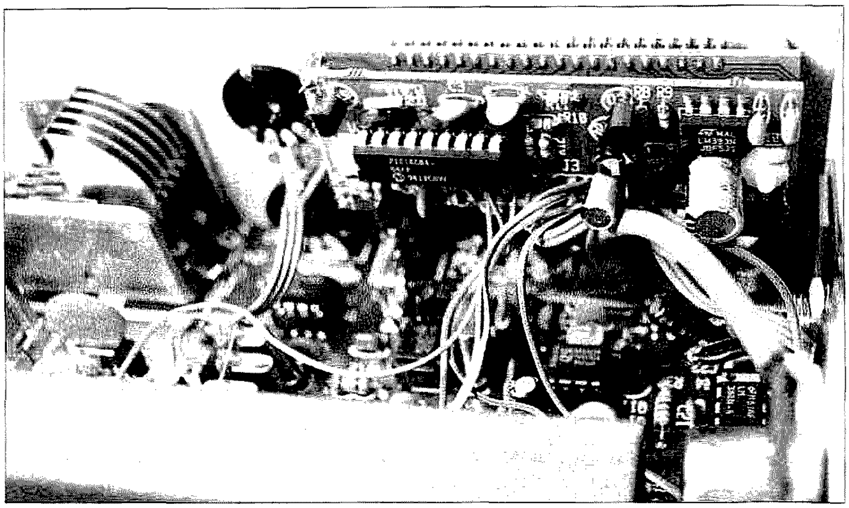

Photo A*. The KC2 installed in the Sierra. The board measures only 1.1" x 2.9" x 0.8".*

Other KC2 features include emulation for Curtis mode A, CMOS Super Keyer II, and Curtis mode B. The speed range is eight to 50 WPM in two-WPM steps using push-buttons supplied with the kit, rather than a knob. The KC2 also features a weight control with eight selectable keying weight levels.

S-meter

The KC2 includes a nifty S-meter bar graph, along with built-in S-meter circuitry. To access the S-meter, the user pushes a button to toggle between the S-meter and the frequency counter.

The input requirements are an audio signal, in the range of DC to 20 kHz, with any rig that uses audio-derived AGC.

Wattmeter

The KC2 also includes a digital RF wattmeter that measures power in the range of zero to 9.9 W in 0.1-watt increments. To access the wattmeter, the user presses the Speed-up and Speed-down push-buttons at the same time, which holds the key-down in a tune function, and measures the power.

The wattmeter is a little more difficult to use with rigs other than the Sierra, because the builder has to put together a small RF detector circuit with five components (these components are already built into the Sierra).

Construction

The kit comes with only 51 components, and can be assembled in one to two hours by an experienced builder. Interfacing it to your QRP kit is very easy, because you have only a few inputs: 12 Volts, ground, dot, dash, VFO, key, S-meter, RF power.

Mounting the KC2 is also very easy. The unit has four momentary SPST switches that mount on the board, and are used to mount the unit behind the front panel of your rig. The user's guide includes a handy template to locate the mounting holes, which are very easy to locate and to drill. The rectangular opening is much trickier. I cut the rectangle by using a Radio Shack™ nibbling tool to nibble the approximate opening, and care-fully filed the opening to the exact dimensions.

As of the writing of this article, Wilderness Radio was gathering user comments from many of the popular QRP kits, and furnishing interface instructions with the kit. Wilderness Radio has also developed an optional front panel for the Sierra, which is custom punched and silk-screened for the KC2.

On the air

On the air, the KC2 is a pleasure to use. It's really fun to operate my QRP rigs with digital readout. I've especially enjoyed using the RIT feature in my Sierra with digital readout to work split frequency QRP DX with more precision.

The KC2's unique combination of memory keyer, 4-digit LCD frequency counter, bar-graph S-meter, and a digital wattmeter makes it the ideal multi-function transceiver accessory for most QRP rigs. Its low power consumption and small size mean that it can fit in a very small enclosure, bringing the power of digital frequency readout and a memory keyer to field applications like back-packing trips and Field Day.

For more information, contact Northern California QRP Club (NorCal), c/o Jim Cates WA6GER, 3241 Eastwood Road, Sacramento CA 95821, (916) 487-3580. To order ($75 plus $3 shipping & handling), contact Wilderness Radio, P.O. Box 734, Los Altos CA 94023-0734, (415) 494-3806.

ARRL Code Survey

Should code be kept as a license requirement?

Alex Haynes AC5HU
Rt. 2, Box 87-C
Eureka Springs AR 72632

It might be news to many of you who are not members of the ARRL, but they are doing an opinion survey about keeping the fast code requirement for earning a ham license.

It may just be my dislike of code showing through, but it seems to me we are long overdue in reassessing the demand that fast code be a requirement for a U.S. amateur radio license.

While code was a necessity for communication in the very early days of radio, it was overtaken long ago by superior technology. And although it is a wonderfully nostalgic way to communicate, in this day and age there is no longer a technical justification for requiring a code proficiency for an amateur license. Sure, I've heard all the arguments over the last 50 years. Some used to make sense, some never did, and a few shouldn't even be mentioned in polite company—so let's leave those until last.

As I understand it, the most important reason code came into use in the early days of electrical communication was the compatibility with the needs of a simple wire-type telegraph system. An on-off signal was the only way to send information, and it worked well. Along came radio and simply turning the carrier wave on and off became the accepted way of transmitting intelligence, just as it had on the telegraph system. Soon, equipment was developed to modulate the RF carrier with sound and AM radio was born. Then FM, single sideband, digital encoding and many other ways were developed to impress intelligence on an RF carrier. My point is, there are many different ways of electronically transferring intelligence and each has its own advantages and disadvantages. Why then should one of them be singled out as the *only* one necessary to master, at a specific speed yet, in order to obtain an amateur license? Code isn't even a technology; it's a psychomotor skill. Thank goodness we don't have an ARRL-like organization controlling our computer hobby, for we all might have to prove we could type 20 wpm on a mechanical computer just because "that's the way Babbage did it." Maybe it's time for the ARRL to adopt a new name more in fitting with their quaint position on code—how about the Antique Radio Relay League? A bit harsh? Perhaps, but at least it would clear the way for a new organization that could speak from a wider perspective, reflecting the views of the vast majority of hams who have chosen not to join the ARRL.

"Maybe it's time for the ARRL to adopt a new name more in fitting with their quaint position on code—how about the Antique Radio Relay League?"

But let's try to understand the logic for keeping a code requirement for ham radio. One claim is that it's a more efficient use of radio spectrum. Something like a 500-Hz bandwidth compared to a 2.5-kHz for SSB. True enough, but since people talk 5 to 10 times faster than they can send code, the real-time bandwidth requirement is comparable for both code and phone. And for digital transmissions, the efficiency of data transfer is many times that of manual CW or phone. But the real hypocrisy of this CW efficiency claim becomes obvious by simply looking at the portions of the 15, 20, 40 and 80 meter bands the code advocates have set aside for themselves. Of course those frequencies are shared with RTTY/DATA, but certainly a "more efficient mode" should not require half of the available spectrum.

Well then, how about communication range: CW is much better, right? Sure, you can often get through with code when you can't on phone and if DXing is your bag, then use the best way available (including digital packet, spread spectrum or whatever) if you want. But why should this justify requiring a code proficiency in order to be granted an amateur license? Why should we even want to force a particular mode of communication on hams? In a free marketplace of ideas, if CW is the best way, wouldn't it come out on top anyway?

All right then, how about "national emergency" communications? Isn't that one of the main justifications for allocating RF spectrum to the Amateur Radio Service? That may have been an

important consideration at one time—long ago. But even our Armed Forces, the Coast Guard and ships at sea have decided to drop code. About the only other people you could communicate with using code would be other hams. Besides, wouldn't the larger number of hams entering the hobby in the absence of a code barrier be a much greater communications asset in an emergency?

Let's face it, for communicating on the go, ham radio has been left in the dust. Most people who want to communicate from cars use cellular telephones. This ought to suggest something to us about where ham radio is headed and just how secure our current frequency allocations might be in the future. Either we increase the size of our lobby or we risk losing our hobby.

How about international treaty requirements? Well, yes, there is an international requirement to send and receive code manually—but there is no speed requirement. The 5, 13 and 20 wpm requirements are arbitrary (and capricious, I believe). They are being forced on the amateur community by a small minority of old fogies in the ARRL and a few dupes at the FCC. The main effect of the code requirement is to reduce the number of licensed amateurs in the U.S.

And now comes the time to discuss what we shouldn't have to discuss. I'd hate to count the times I have heard the sentiment "I had to learn code and so should every one else who wants to be a ham—besides, it cuts down clutter on the bands." A shameful attitude, to say the least. And, of course, readily denied on every official level. Look, the ARRL will say, we sponsor an extensive amateur licensing program intended to increase our ranks. But who, nowadays, really doesn't understand the concepts of hidden agendas, countervailing policies and just plain old-fashioned doublethink? It strikes me that many hams have abandoned most intellectual arguments for code, but still cling to this selfish "I got mine the hard way and so should you" attitude. Many bright young potential hams reject the notion of being forced to master a skill they see as irrelevant—they just don't have time for this nonsense.

Without this unnecessary barrier, how many more hams could we have had by now to build, experiment, innovate, manufacture and buy equipment? Take a look at all the domestic parts and equipment manufacturers that have folded over the last several decades. Then look at some of the Asian countries with minimal code requirements and large ham communities—the ones that produce most all of our new ham equipment.

I certainly don't want to leave the impression I am totally anti-ARRL, because I am not. But it just seems so obvious the ARRL is on the wrong side of the code issue, and they have been for so long, it is difficult to give them the credit they deserve for all the other good they do.

The ARRL's intransigence on the code requirement has caused the unfair exclusion of a significant portion of the public from equitable access to a public resource, and for this the ARRL should be held accountable; it is why I dropped my ARRL membership more than 20 years ago. For this and a variety of other reasons many hams refuse to support the ARRL (only about a quarter of all licensed hams are members) and their claim to represent a consensus of opinion among hams needs to be closely scrutinized. We should not forget the ARRL is a *private* organization and is answerable only to its members, virtually all of whom are licensed amateur radio operators. So how is the voice of the rest of the American public and the other 75% of hams represented in this equation? Well, supposedly through the FCC. But wait a minute, who does the FCC depend on to advise them in setting public policy for amateur radio? Who else but the ARRL?

"A 'more efficient mode' should not require half of the available spectrum."

Most hams (and non-hams) have very little direct voice in setting public policy for amateur radio, except for the occasional congressman who might take an interest in a specific issue (but who probably is also a ham) or a manufacturer with a proprietary interest. So, because of this typical incestuous relationship in which the "public regulator" (in this instance the FCC) becomes a pawn of the supposed "regulatee" (amateur radio special interests), many aspects of public interest issues are never fully explored. If code is so important, why is there no requirement for periodic testing to prove continued proficiency? After all, high speed code is a skill of the use-it-or-lose-it type. It is not the kind of logical intelligence that is learned once and retained for a long time. Fast code must be routinely exercised or is rapidly lost. And this leads to perhaps our dirtiest little secret.

My guess would be that at least half of U.S. amateurs (probably far more) currently are unable to copy code at the speed required by their license class. I doubt the ARRL could prove otherwise. I would go even further and claim most hams don't use any code at all and have lost virtually all ability to send and receive code. So, are we in violation of the intent of "international treaty"? Does it matter? Does anyone care?

Surely the FCC must know the vast majority of licensed hams can't effectively communicate using code. So how can our government continue to bend to the hypocritical demands of the ARRL? The simple answer is they should not and in the long run, they cannot! I would hate to be the bureaucrat assigned to defend the code requirement in court if it ever comes to that. There is no significant data to support the continued need for code, no logical justification based on current technology and, quite to the contrary, a strong case can be made that the code requirement is clearly discriminatory against certain categories of protected individuals.

Don't get me wrong here—I'm all for an incentive licensing system based on technical merit as it relates to the real needs of our hobby—but I do take issue with the requirement to master a long-irrelevant psycho-motor skill which unfairly excludes otherwise fully qualified and capable people from the hobby.

The survey

So now the ARRL has decided to fund a study of our current opinions about retaining the fast code license requirement in preparation for the upcoming World Radio Conference, WRC-99.

Although I have not been solicited to respond to the survey by their contractor (the READEX Company) and am apparently excluded also from replying to their request in *QST* for input from members (presumably ARRL members,

which I am not), I would like to take this opportunity to express my thoughts on the issue.

My initial impression upon reading through the survey form was that several of the questions are so poorly worded as to be misleading and likely will be misinterpreted by many of the respondents. Other questions have multiple premises which offer the possibility of at least four conditions, the responses to which will be impossible to accurately interpret. Many of the other questions seem to be asking virtually the same thing over and over, with most of the possible answers indicating a preference for at least some level of code speed proficiency—not a very good way to get unbiased results.

The likely results of such a survey are rather predictable—ARRL members who have already passed their code test will favor its retention and nonmembers who aspire to upgrade will tend to vote in the opposite direction. Unfortunately, the voice of the vast majority of technically qualified but as yet unlicensed individuals will be virtually unrepresented in the results of the survey. And it is among this last group that we suffer our greatest loss, for it includes many of our newly trained scientists, engineers and technicians, who could contribute greatly to the hobby but who are excluded by the outdated, outmoded and just plain foolish code speed requirements.

The ARRL survey has three sections covering the international requirement for Morse code, U.S. licensing requirements and personal data. The questions are repeated below, along with my comments.

PART I. Morse Code

1. Which of the following two statements is closer to your opinion with regard to a possible change in the international regulations?

A. The Morse code requirement for Amateur Radio licensing is no longer relevant, or soon will not be relevant, in the international regulations. *Comment: This option requires the respondent to make a conclusion about the current position and future action of an international body—a speculation which is beyond his reasonable knowledge. The question is confusing and does not give him a real opportunity to simply select his position, thus likely biasing the overall result.*

B. For the foreseeable future, it is important to retain the Morse code requirement in the international regulations. *Comment: This option, in comparison to the previous one, gives the respondent a simple and direct way to state his opinion—in favor of code.*

2. Please SUPPORT the reasons for your position by indicating your agreement or disagreement with each of the following statements:

A. Each country should be able to make up its own mind whether to have a Morse code requirement, or not. *Comment: Presumably this refers to each country that is a party to the agreement. Since not all countries are, and all countries have a sovereign right to do what they want about requiring code anyway, it seems like sort of an odd issue to pose to U.S. amateurs. Since it is a truism, most U.S. amateurs would probably agree we should not attempt to tell other countries whether or not they should have a code requirement. The real issue is, should the FCC (at the ARRL's urging) require U.S. citizens to learn code at a specific speed of up to 20 wpm? Since the FCC has been requiring this for many decades without any international requirement to back them up, can we now expect the FCC and ARRL to be preparing the way to continue a code requirement in the U.S. even if it is dropped elsewhere around the world? This of course would be really dumb, but it also would be in line with the ARRL's long-standing preference for fast code.*

B. The Morse code is still important because it helps amateurs to communicate across language barriers. *Comment: While it is undoubtedly true that code is "still" used, the issue is one of "importance." Computers and other types of digital communications are far more efficient in this regard. To cling to a requirement for a manual capability to communicate in code for this reason, to the exclusion of other far better methods, is misguided.*

C. The Morse code requirement helps insure that radio amateurs are disciplined operators. *Comment: Clearly, this one is not verifiable in any way, shape or form, and there are just too many glaring examples to the contrary. I also wish all hams to be good and decent people, but code is not the answer to any part of society's ills and it's embarrassing to see hams being asked to parrot such ridiculous claims.*

D. The Morse code is a good thing to know, but it should not be a licensing requirement. *Comment: This is one of several two-part questions that offer four possible outcomes. Suppose someone thinks code is dumb, never uses it and has even lost all code capability, but selfishly wants it retained as a license requirement in order to reduce clutter on the bands? And regardless of how he checks the boxes, they won't have the foggiest idea of what he really thinks. It simply is an example of a bad question.*

E. Knowing the Morse code just isn't important any more. *Comment: This question is an excellent example of steering the respondent to the desired conclusion by a variety of preceding questions stated in such positive terms as to elicit a desired reaction type response. Besides, as in the previous question, simply "knowing Morse code" isn't the issue—using it at a specific speed is, and the speed requirement has nothing to do with international agreements.*

F. If rules for Amateur Radio were being written for the first time today, there would not be an international requirement of Morse code ability for access to the HF bands. *Comment: Again, as in Question 1, the respondent is being asked to speculate and make predictions about the possible actions of an international body of which he has very little knowledge. The value of any response to such a statement is questionable. If the word "should" had been used rather than "would," at least the respondent could have reflected his own opinion in his response.*

PART II. License Requirements

Comment: Almost all of these questions are concerned with current FCC requirements (instigated by the ARRL) relating to code speed and incentive licensing, neither of which results from or has any impact on international agreements. This unfortunate juxtaposition under the guise of preparing for WRC-99 serves to reinforce the erroneous association in many hams' minds that code speed licensing requirements are somehow a result of international agreement. Again, this is an example of steering the respondent and, unfortunately, there is no way to eliminate the resulting bias from the results.

PART III. Personal Information

Comment: Somewhere among all these demographic questions about age and license class, etc., it would have been instructive to have asked about the respondents' real code capabilities at present, educational attainment and technical contributions to the hobby, such as patents and papers.

So what will the survey really contribute to the body of facts that should be used in developing our position on code for WRC-99? Apparently very little. Our position should be based on what is good for amateur radio, and not on the desires of a small proportion of hams—hams who simply want to protect or enhance their own privileges.

The real issues used to decide our position should be ones of fact, such as:

• How does a code proficiency contribute to amateur radio?
Facilitates international communications.
Provides somewhat longer-range communications.

• How does a code requirement detract from amateur radio?
Excludes a large number of technically qualified individuals from the hobby.
Has resulted in underutilization of frequencies and their loss to commercial interests.
Has contributed to the erosion of U.S. amateur radio equipment development and manufacturing capabilities.
Has slowed the development of competing technologies for impressing intelligence on RF carriers.
Discriminates against some handicapped individuals.,

Too bad the ARRL survey will not be able to provide meaningful data on the really important issues. Let's hope the U.S. representatives to WRC-99 will be able to see beyond any misguided attempt to influence their recommendations with "cooked" survey results and act in the best interests of all our citizens, not just currently licensed hams.

NEVER SAY DIE

Continued from page 17

are also not available to the public? That's weird! It's almost enough to make someone suspicious.

Bill, who worked for Rocketdyne for seven years, designing and building rockets for NASA, had his curiosity aroused when he heard that the lunar missions would be using rocket engines which he knew were far too small to lift the lunar payloads. The larger engines, which had been designed to take people into space, had all failed. 13 consecutive failures! He knew that the smaller engines that were being used couldn't possibly do more than lift a rocket with no payload. Hey, what's going on here? And then, after this long string of failures, the moon missions came off one after the other like clockwork. Hmmm.

It's sure an interesting book, but since you know that your government could never keep anything this big a secret, you probably won't want to bother reading it. Just chalk this up to poor old Wayne falling out of his rocking chair and probably hitting his head. Or being incredibly gullible.

If you'd like to read Bill's book I'll have him make up some copies. $25, plus $3 s/h from Radio Bookshop, 70N202, Peterborough NH 03458. Cash, check, money order, Visa, MasterCard, or what have you to swap?

Scientist Welfare

Congress sure has a lot of fun spending our money. Being interested in science, I almost get upset when I see Congress throwing money away on projects that don't make good scientific sense. Sure, I realize that Congress is made up mostly of used lawyers who haven't a clue when it comes to science, so they can be easily gulled by our beloved scientific establishment. You know, the turkeys who have managed to ignore virtually every major scientific discovery in history.

So they blew a few gigabucks on that big hole in the ground down in Texas. The supercollider. And they're still throwing gigabucks at the NASA Mars project. Did

anyone notice that Russia got all over their desire to send men to visit other planets when they found out that their astronauts would get fried by solar flares if they ever ventured outside the protection of the Van Allen belt? The Russian space effort is just about closed down now. Oh, they have the money, if they want to use it—I noticc that they haven't slowed down on their building of new and more advanced nuclear submarines. Hmm, I wonder what they need *those* for?

Then there's that $200 million shoulder of pork being spent on the HAARP deal in Alaska. I've mentioned this scam before. The idea is to shoot 1.7 billion watts of RF into the ionosphere and let's see what happens. That's a lot of juice, but it's a piffle in the wind compared to the soup arriving from the sun from solar flares.

There are a bunch of basic research projects which really could use some funding, so I hate to see Congress blowing money on pork fat like the Alaskan HAARP and Mars charades.

Pork Chop Hill

Despite all that campaign rhetoric about the deficit and cutting the budget, the guys you recently blindly re-elected (despite my warnings), have been busy pigging out on your money. As hams, I suppose we should be tolerant of pork, such as the $25 million for our wonderful friends in North Korea. Hey, we sure don't want to watch our good communist buddies go broke building tunnels under the DMZ, right?

How about $1.9 million to supervise a Teamsters election? Or $3 million for a New Orleans Jazz Historical Park. And $1 million for the Center for Irish Management. Hmm, are those pesky Irish getting that far out of hand? Or around a half mil for the Applewhite Picnic Area in California. And $8.6 million for anti-terrorist operations by the National Park Service. So *that's* where the terrorists are concentrating their efforts! Manhattanites, you can relax.

Hey, it's *your* money they're having all that fun with. Next time get out there and vote and be sure to Never Re-elect Anyone (NRA). Let's flush that lousy Washington toilet and send all those professional politicians home to find honest work. Back to their law firms.

Superhuman

Every now and then I read about someone doing something superhuman under extraordinary circumstances. A mother lifts a car off her child, for instance. And many hypnotists have demonstrated amazing feats of strength or enhanced other abilities with their subjects. LSD users will tell you about their incredibly enhanced senses of taste, smell, hearing, and extrasensory perception (yes, I did LSD back in 1960 and it was an incredible experience!).

Are You Ready To Recharge?

Learn about a new battery technology—then build the project to utilize it.

Sam Ulbing N4UAU
5200 NW 43rd St. Suite 102-177
Gainesville FL 32606
E-mail: n4uau@afn.org

One of the fun aspects of ham radio is that electronics technology changes so fast. It seems every week a new product is announced that can affect ham radio—I recently learned about a relatively new battery technology and discovered a chip that I could use to build a charger for this battery. If you're not familiar with "rechargeable alkaline batteries," read on. I think you'll agree that they offer advantages for the radio amateur.

Building the charger is an easy project and the batteries are inexpensive. Once you've built the charger you can try using rechargeable alkaline batteries and see how well they perform for your applications.

What are rechargeable alkaline batteries?

The technology for these batteries is quite new—it was developed in 1986 by Battery Technologies, Inc., and the batteries were first introduced in September of 1993 by Rayovac™ under the brand name RENEWAL© (several other manufacturers are also producing rechargeable alkalines now). A charging chip, the bq2903, was released to the industry and to the public by Benchmarq™ in the spring of 1996. Prior to this only the Rayovac recharger was available.

Normal alkaline batteries are "primary" batteries; that is, you use them until they are dead, then throw them away and go buy more... and more and more. Rechargeable alkaline batteries are modified alkaline batteries which, like NiCds, are "secondary" batteries that can be used over and over, but their features are quite different. Under the right conditions rechargeable alkaline batteries can be used and recharged hundreds of times. Under the *wrong* conditions they can be destroyed after only a few uses.

These batteries are still new enough that you might have to hunt a little for them; they can be found at mass marketers like Wal-Mart™, KMart™, Target™ and ACE™ hardware. I also found some at the local supermarket but could not find any at Radio Shack™. To raise consumer awareness, Rayovac has been running an ad campaign for them featuring Michael Jordan, so you may soon be seeing more of them.

"If you use a NiCd charger to charge rechargeable alkaline batteries you'll kill them."

Why would you want rechargeable alkaline batteries?

• Compared to using alkalines, you could save money. A package of 4 primary AA alkalines costs about $2.80, while four rechargeable alkaline batteries cost about $5.50 and four NiCds are about $10.50. If you have an application that needs 5 volts at 125 mA and runs only half an hour a day, over three years you will have to buy 34 sets of 4 alkaline batteries at a cost of $95.20. With proper care, the rechargeable alkaline batteries should still be good and you will have saved $90. The NiCds would also be good but the rechargeable alkaline batteries are still less expensive.

• Compared to NiCds, they have a much longer shelf life. This means you can depend on them when you need them. Fully charged rechargeable alkaline batteries will still have 96% of their charge after sitting around for a year. If you leave fully charged NiCds unused for only three months, you will have to recharge them before you can use them because they will only have about 25% of their capacity left.

• They are environmentally friendlier than NiCds because they contain no cadmium—and you discard fewer of them than you do primary alkaline batteries.

The right conditions

Each battery system has different strengths and weaknesses. Selecting the best battery for a particular application requires knowing the right conditions for a particular battery. Rechargeable alkaline batteries work best under the following conditions:

• *Low current use*

Because of their construction rechargeable alkaline batteries have a rather high internal resistance. For this reason they work best when the current draw from them is limited to a few hundred milliamps. A continuous current draw of less than 400 mA is best although they can supply up to 1 amp in instantaneous peaks with a reduced voltage. Studies done by Rayovac show that a rechargeable alkaline battery which is always deeply discharged (to 0.9 volts) before it is recharged will lose about half of its initial capacity by the 25th use. Even so, at low current levels the overall capacity available for the first 25 uses of rechargeable alkaline batteries is about equal to that of 10 primary alkalines and as good as or better than NiCds, even

assuming NiCds lose no capacity with use (see **Table 1**). This might be considered a worst-case use (under proper use) of the batteries.

• *Recharge often*

Rechargeable alkaline batteries like to be recharged often—exactly the opposite of NiCds which can lose capacity from "memory" effect if they are not fully discharged before being recharged (see Author's Note). Rechargeable alkaline batteries gain capacity from frequent recharging so you don't have to worry about doing it too often.

Rayovac conducted a test in which batteries were discharged at 400 mA for 10 minutes and then immediately recharged. This cycle was repeated several hundred times with no significant change in cell response observed. In this case the battery capacity was greater than 53,000 milliamps/hours, 26 times as much as for a primary alkaline battery. This is probably a best case for the battery, but under proper care you could get somewhere between 10 and 25 times the life of a primary alkaline battery.

• *Recharge properly*

NiCd chargers use a constant current charge technique and measure either cell voltage or temperature to terminate the charging. If you use a NiCd charger on rechargeable alkaline batteries you'll kill them quickly. The proper method is to pulse the current to the battery and in between pulses check the no-load cell voltage. The average pulse current needs to be reduced as the battery voltage increases to avoid overcharging. This project uses the proper charge method.

• *Avoid deep discharging*

Rayovac and Benchmarq both clearly state: "The most important factor in maximizing the cycle life of reusable alkaline batteries is the avoidance of overdischarge or cell reversal." We have seen that cycling batteries to 0.9 volts gives less capacity than short cycling. Discharging below this voltage level will significantly shorten battery life. NiCds, too, are injured by overdischarging and cell reversal, but it appears that for rechargeable alkaline batteries the damage is much more severe; that's why the Benchmarq charging chip is designed to be used *with* the battery pack, when the battery pack is in use, to prevent overdischarging.

We've focused on AA batteries. C and D cells will have more capacity than AA cells but the optimum rate of charge and discharge appears to be about the same as for AA cells. This means that you will get more hours of use from the larger sizes—but probably not much more peak current output. The charging circuit (**Fig. 1**) will work with the larger sizes but it will take longer to fully charge the batteries.

Charging the batteries

When you first power up the charger, it checks to see if any cell has a voltage of less than 0.4 volts, and indicates a defective cell fault by flashing the "CHG" LED. If no cell is less than 0.4 volts and the voltage at pin 13 is 2.7 volts or more, it starts the charge cycle (the "CHG" LED is on continuously, not flashing). The bq2903 uses a pulsed current charge method. An internal FET is switched on for 7.5 ms and then off for 2.5 ms by circuitry internal to the bq2903. The chip monitors the voltage of each cell between pulses.

Current Demand	100 mA	300 mA
Alkaline Primaries	2,100 mAh	1,550 mAh
Rechargeable Alkalines	25,000 mAh	15,000 mAh
NiCds	17,500 mAh	15,000 mAh

Table 1. *Comparison of cumulative battery capacity over 25 uses (discharging to 0.9 volts with each use).*

Note that the charge current is applied to the whole stack of cells at pin 14 and not to each individual cell. Pins 1, 2, and 3 are used only to monitor each cell's voltage—a compromise, because ideally each cell should be charged and monitored. This compromise is quite acceptable as long as cells are matched. Charging new and old batteries in the same stack is not recommended, because of their change in capacity. If, during charging, the bq2903 measures any cell voltage greater than 1.63 volts, it skips charge pulses until all the cells drop below 1.63 volts, or until so many pulses are skipped that the average pulse charge rate is 6% of the maximum charge rate. At this point charging is terminated. The "CHG" LED turns off and the "DONE" LED turns on.

After charging, the charger stays in the monitor mode checking battery voltage. A trickle charge is not needed as it is for NiCds because of the very low discharge rate of rechargeable alkaline batteries. If the batteries were left in the charger for a very long time, and all cells fell below 1.4 volts, the charger would initiate another charge cycle.

R3, R4, and R5 limit current to the chip. The capacitors are for transient suppression.

If you wish to modify the circuit to charge only three cells, you can do this by disconnecting Nsel (pin 4) from Batlp (pin 14) and connecting it to Vss (pin 10 or 11). You also need to connect pins 2 and 3 since only 3 cells are in use.

The maximum recommended charge rate for the bq2903 is 400 mA and the maximum voltage is 10 volts. The power source must limit both. A minimum of 8 volts is necessary for four cells. Lower charge currents will permit deeper recharging. I decided to limit current to about 300 mA. 12-volt transformers are inexpensive and readily available so I used one for my power source. Since wall transformers do not regulate the output voltage nor limit the current, I used two LM317 regulators to limit the maximum current to 300 mA and maximum voltage to 9 volts.

It is possible to use a standard four-cell battery holder with the charger but it must be modified—and that may be difficult. The need to measure the voltage of each cell requires that a wire be soldered to each spring terminal of the holder. I succeeded once but another time the heat melted the plastic and I ruined the holder. Using four single-cell holders will permit access to each cell (**Photo A, Photo B**).

Using the bq2903 to control end-of-discharge voltage

You can remove your batteries from the charger and use them when they are charged. If you follow the guidelines, you should get a long life from them.

If your application has room to include the charger circuit, the bq2903 will also monitor the cell voltages as they are discharged and disconnect the battery source from the load when the voltage drops to a set level. Pin 5 is used to set the shutdown level. Because the voltage is being monitored under its discharge load, the measured voltage will appear lower than the actual cell voltage. For best results, that end of discharge voltage should be set as shown in **Table 2**.

The bq2903 terminates discharge by disconnecting the internal discharge FET and entering a standby mode drawing only 1 μA.

Component Values for Schematic (all 1/4 watt)	
R1, R2	620 ohm
R3, R4, R5	1 k
C1	1 μF
C2, C3, C4, C5	0.1 μF
D1	Red LED
D2	Green LED

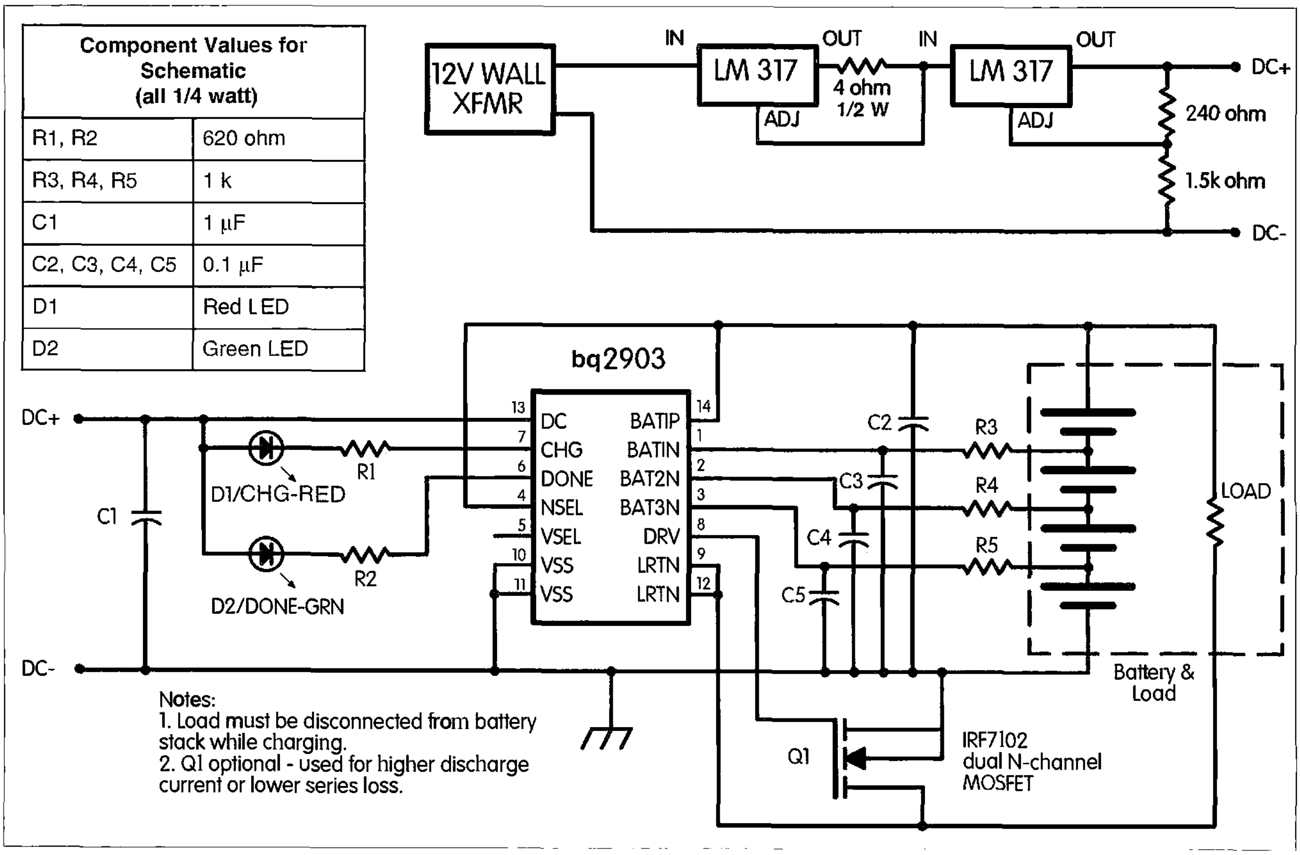

Fig. 1. The author's charging circuit.

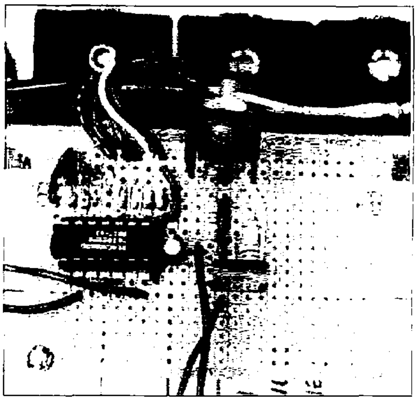

Photo A. A prototype recharger, built on a Radio Shack universal PC board.

The discharge FET is between the load return and Vss (the bottom of the battery stack). The resistance of the internal discharge FET is about 1/2 ohm. Discharge loads should be limited to 500 mA. At higher loads it is possible to use an optional external FET in parallel with the internal FET. Pin 8 is used to control the gate. If you are not using an external FET then leave pin 8 unconnected. The external FET must be a low resistance logic level FET, like the type shown in the schematic.

I've been using rechargeable alkaline batteries for about a year. I have not done scientific testing—I'll leave that to the engineers, but I *have* tried them in a variety of situations.

I've used rechargeable alkaline batteries to power the "SMALL" audio amplifier circuit (*QST*, June 1996) I built (with the 7805 removed). The "SMALL" can require peaks of 400 or more mA. I found no difference in audio volume (which depends on input voltage) between using rechargeable alkaline batteries and NiCds. I have let it sit for long periods with rechargeable alkaline batteries in it and occasionally turn it on. It still sounds good.

I've used rechargeable alkaline batteries in my handheld GPS. If you have one you know that they eat up batteries at a rapid rate. Primary alkalines lasted about 10 hours. NiCds and rechargeable alkaline batteries both lasted about half as long. If you plan to use your GPS only for short periods and then store it for a few weeks, rechargeable alkaline batteries will keep it ready to go.

Life-testing batteries takes a long time and there are many variables. I'd be interested (and I suspect *73* would be, too) in hearing what those of you who do this project learn. No one battery is perfect, but knowing *which* one is the best for an application can help you get the most from these expensive power sources. For those of you who are inter- ested, more information may found on the World Wide Web: http://www.rayovac.com/business or http://www.benchmarq.com.

The bq2903 is only available from wholesale distributors at this writing. However, a parts kits with PC board and all the parts shown in **Fig. 1** except Q1 and the wall transformer are available from me for $17.50 including shipping (Florida residents please add sales tax).

Author's Note: There are various opinions on memory effect: Recently a column in QST *(October 1996) suggested that memory effect does not normally occur. I offer this, based on a statement by John Wettrroth of MAXIM, who wrote in "Ideas For Design"* (Electronic Design *Magazine, January 22, 1996): "The microcrystalline cadmium in a NiCd battery's anode will slowly begin to change if left undisturbed. Tiny crystals in the metal coalesce into larger ones, producing an increase in battery resistance that lowers the terminal voltage. This effect can become noticeable when repeated partial discharges leave the lowest layers of cadmium unaffected ... as a result, a full discharge eliminates the reduction in terminal voltage, sometimes (erroneously) called the memory effect."* 73

For discharge rate of	End of discharge voltage (per cell)	Connect Vsel to
50 mA	1.1 volts	pin 14
100 mA	1.0 volts	not connected
more than 200 mA	0.9 volts	pin 10 or 11

Table 2. End of discharge voltage.

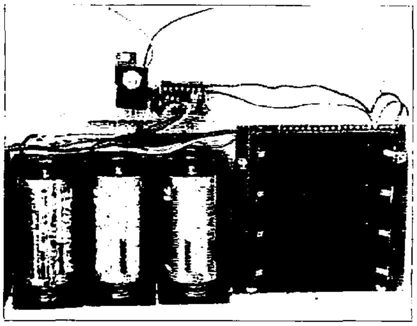

***Photo B.** Notice the recharger is set up to charge either "AA" or "C" batteries.*

NEVER SAY DIE

Continued from page 39

Then there are people with special abilities—math, memory, musical, etc. Prodigies.

All these experiences tell us what the human body/mind is capable of doing. The question is, how? If we can understand how people can do these things, perhaps we can harness it for everyone's benefit.

Let's also include "spontaneous cures" for serious illnesses, while we're at it.

You don't have anything better to do, so get busy on this.

Virus!

We all catch colds and the flu every now and then, right? While we're able to catch germs and viruses in different ways, generally we think of it as being through physical contact, or perhaps airborne (like from a sneeze or cough).

I've had less trouble with catching colds since reading an article which recommended shaking hands with the right hand and using the left to touch my nose or lips. At trade shows, hamfests, and conferences I try to remember this warning, and it's pretty well ended my coming back sick after shows.

Of course another pretty good way of avoiding colds and flu is to keep your immune system strong and avoid stress. I do my best to keep my immune system strong by getting the best air, water, and food I can, by adding missing minerals and vitamins to my diet, and by avoiding obvious poisons such as nicotine, alcohol, mercury (via dental fillings), root canals, aspartame (a.k.a. NutraSweet™) and electromagnetic fields.

I get out there and exercise every day, letting some of those valuable sun UVs into my eyeballs.

But there's another source of viral contagion which has been hushed up by our trusted medical industry. I got the first hint of this when I read the Hoyle-Wickramasinghe book, *Diseases From Space*, which showed that most of the world's more serious plagues started

Top-Fed, Out-of-Phase, Phased-Verticals (TOP) Antenna

Computer simulated and field tested.

Nizar A. Mullani KØNM
719 Santa Maria
Sugar Land TX 77478
E-mail: K0NM@amsat.org

Here's a new, simple phased-verticals antenna that is easy to build and which does not require ground radials or a counterpoise. The antenna consists of two half-wave radiators with a 180-degree phase difference that is fed at the top with 50 ohm coax. Computer simulations and prototype tests show an SWR of less than 1.4 to 1 and the radiation to be a bi-directional figure-8 pattern that is in line with the two vertical radiators.

HF possibilities are appealing because no radials are required and the separation between the verticals is quite small. In fact, it can even be made to rotate (only for an unguyed tower) by attaching the antenna to the boom of a yagi. Or, the antenna can be turned to the horizontal position for an end-fed two-element out-of-phase bi-directional antenna.

In the VHF frequencies, where the antenna is suspended several wavelengths above ground level, the TOP antenna will not match up to the gain of a yagi; however, it will have a couple of dB gain over a J-Pole antenna. The bi-directional nature of the radiation pattern makes it an ideal antenna for stations located between two major cities.

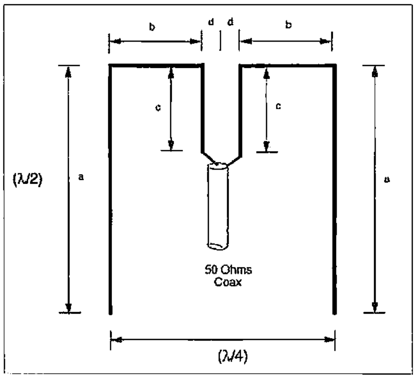

*Fig. 1. The TOP antenna, showing the approximate dimensions and the feedpoint. Values for the different lengths and spacing are shown in **Table 1**.*

Just the facts

Radiation patterns from phased verticals vary, depending on the spacing between the verticals and the phasing of the radiators. The feedline coming from the transmitter has two lines which are 180 degrees out of phase at any one time. Therefore, feeding the two vertical elements with each end of the feedline automatically causes a 180-degree out-of-phase feeding of the two elements of an antenna.

Most phased verticals have feedpoints at the bottom, with feedlines of different lengths to provide the phasing and extensive ground systems. Unfortunately, the wires that connect the vertical radiators carry a fair amount of current close to the ground and the radiation from these wires is absorbed by the ground. Feeding the antennas from the top elevates the high current points to a higher level away from the ground and keeps the current at the ends near the ground very low. Therefore, most of the radiating power of the antennas is raised above ground level for effective radiation of the signal and no ground radials are required. The design described here is simple, easy to build, and provides some gain and directionality in-line with the two phased elements. Additionally, it can be fed directly with 50 ohm coax for a low SWR, and overcomes some of the complexities inherent in these antennas.

The design of the TOP antenna is shown in **Fig. 1**. The antenna is basically two half-wave vertical radiators fed at the top with a feedline and impedance matching section that is part of the antenna. The shape of the antenna resembles the letter "m" and is symmetric about the feedpoint. The dimensions of the antenna are shown in units of wavelengths for illustration purposes. In theory, the lengths of the vertical and the horizontal sections can be any size; however, the radiation pattern and the feed impedance will change depending on these dimensions. With larger spacing, a significant amount of horizontally polarized signal will be radiated by the top horizontal feed section. Closer spacing will increase the gain but lower the feed impedance.

Getting creative

Using the AO computer program, I simulated a compromise design which trades some of the gain for ease of feed of the antenna. This design utilizes two half-wave verticals with a spacing of a quarter wavelength, and a feed system with impedance matching, to provide a feed impedance of 50 ohms. The matching section is folded down from the top as shown in **Fig. 1** to keep the total design compact.

Dimensions of Sections **a**, **b**, **c**, and **d** can be computed easily using the following equations, but there will be some deviation from these values, especially in the spacing **d** (impedance at the feedpoint). The values below will also need to be adjusted for the thickness of the wires used in the antenna. The values

shown below are for use with #12 wire.

$$a = \frac{468}{f} \qquad b = 0.160a$$
$$c = 0.36a \qquad d = 0.05a$$

where f is the frequency in MHz , and a, b, c, d are in units of feet. The size of the conductor will influence the above dimensions, especially d, which is responsible for the impedance matching.

Computer simulations of the TOP antenna

The computer simulations for **Fig. 1** (AO Program) were carried out for a perfect ground system with the antenna being one inch from the ground. A similar set of simulations were carried out for a quarter-wave ground plane antenna at the same height above ground for comparison purposes. Simulations were carried out for several different HF and VHF frequencies and the typical values useful for different bands are shown in **Table 1**. Additionally, the VHF antenna was built and tested and the results are compared to the simulations.

Computer simulations of the 20-meter TOP antenna

Using normal ground rather than perfect ground, initial computations for a 20 meters version were done using the AO program, but the final results were made using the NEC-2 program, which is better for computing the losses due to close proximity of an antenna to the ground. A center frequency of 14.2 MHz was used and the dimensions used for the antenna are as shown in **Table 1**. A quarter-wave ground-plane antenna was also simulated and the results of the two antennas are shown in **Fig. 2**. Both antennas were simulated with their lowest point being one foot off the ground. Horizontal radiation patterns show a classic figure-8 radiation pattern in-line with the two vertical radiators for the TOP antenna. (The radiators are positioned north-south.) Vertical radiation patterns show the higher gain for the TOP antenna compared to the quarter-wave ground-plane. At the five-degree angle of radiation, the TOP has approximately 4.5 dB more gain than the quarter-wave ground-plane. Also, the front-to-side comparison for the TOP antenna shows a 13 dB difference.

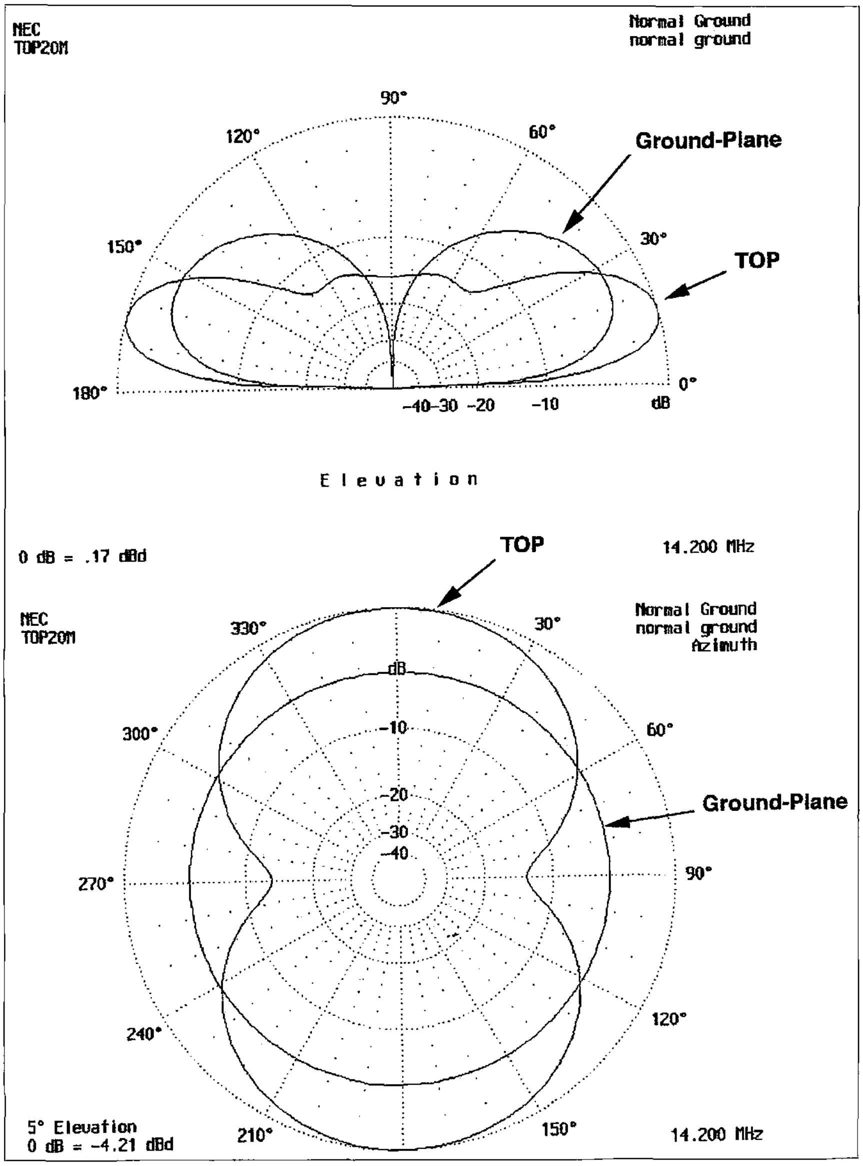

Fig. 2. Simulations using the NEC-2 computer program for a 20-meter TOP antenna compared to a quarter-wave ground-plane at a height of one foot above normal ground for both antennas.

Computer simulations of the 2-meter TOP antenna

The TOP antenna was also simulated for VHF operation, using a center frequency of 146 MHz (dimensions used in this simulation are shown in **Table 1**), along with a quarter-wave ground-plane antenna. Both antennas were positioned one inch above perfect ground for gain calculations. The radiation pattern is shown in **Fig. 3** with superimposition of the radiation pattern of a quarter-wave ground-plane antenna as a comparison. As expected, the two half-wave radiators provide a lower angle of radiation with a gain of approximately 4.5 dB over a quarter-wave vertical antenna. The radiation pattern is a figure-8 shape with the maximum radiation occurring in-line with the two vertical elements. According to the simulation program, the impedance at the feedpoint is approximately 45 ohms for 3 inch separation (d=1.5 inches) of the wires in the matching section. This impedance increases to 51 ohms with 4 inch spacing (d=2 inches) between the wires. Additionally, the SWR can be adjusted by increasing or decreasing the length of the vertical radiators.

Testing the 2-meter antenna

I built (with the help of WA5TWT) a 2-meter TOP antenna using the

dimensions shown in **Table 1**. The basic structure was built of wood and #12 wire. The antenna was fed directly with 50 ohm coax and the length of the vertical section was adjusted to lowest SWR by pruning the length. The measured SWR was less than 1.4 to 1 for operation within 2 MHz of each side of the center frequency. Rotation of the antenna yielded a bi-directional figure-8 field-strength pattern, as expected from the simulations. Field strength meter readings showed a front-to-side ratio of ten to one. Operation of the antenna at approximately six feet off the ground, with 3 watts of power, produced full quieting signal into a repeater 15 miles away and repeaters as far away as 40 miles could be used. When the antenna was rotated 90 degrees, the signal level decreased by approximately 15 dB and white noise was noticeable on the signal (courtesy K5HFY and N5EM).

Author's Note:

Since the original writing of this article, I have built 15-meter and 17-meter TOP antennas and tested them. The 15-meter was first laid out on the ground, assembled, and then raised over two branches of a tree in my back yard with the help of a slingshot and rope. The antenna was pointed north-south, of necessity.

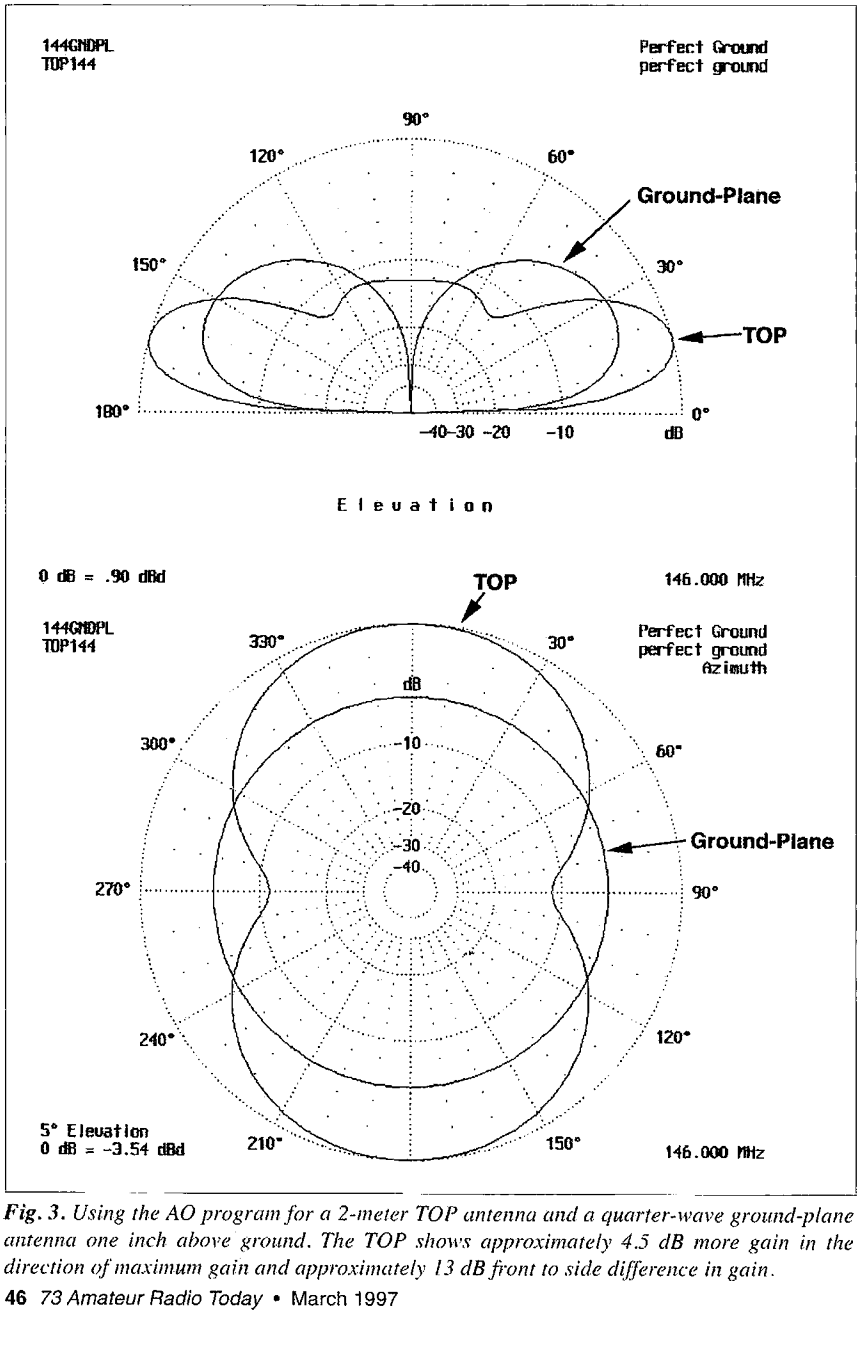

Fig. 3. Using the AO program for a 2-meter TOP antenna and a quarter-wave ground-plane antenna one inch above ground. The TOP shows approximately 4.5 dB more gain in the direction of maximum gain and approximately 13 dB front to side difference in gain.

I connected the coax to my Autek SWR analyzer and adjusted the lengths of the vertical sections to get the lowest SWR of 1.4 to 1 at 21.15 MHz. I fired up my ICOM 738 and it showed an SWR of less than 1.7 to 1 across the whole band with an SWR of 1 to 1 from 21.1 to 21.4 MHz. I didn't even need my automatic tuner to load up this antenna.

I always test my antennas using a reference quarter-wave ground plane antenna. First, I did a receive test, switching back and forth between the TOP and the quarter-wave ground plane. The South American stations were coming in one to two S-units stronger with the TOP antenna. On transmit, with 100 watts, I found the same sort of report from LU7, ZP5, XE2, TI2, WDØ in Colorado; consistently one to two S-units better.

Not being satisfied with the success of the 15-meter antenna, I wanted to see if I could stretch my luck and little and convert the 15-meter antenna to a 17-meter antenna by simply adding a few more feet of wire to the vertical wires. Sure enough, adding six feet to each end brought the SWR down to 1.5 to 1 at 18.09 MHz and my ICOM got generous and gave me 1 to 1 SWR across the 17-meter band. I don't have a ground plane on 17 to do a direct comparison by I had no problems working into PY1, ZP5, or connecting with Guadeloupe on first call. That evening, I capped off the testing of the antenna with a nice QSO with Tony N5ZIT/MM, who was maritime mobile off the coast of Brazil. It was solid 5-9 signal for half an hour and one of those heart-warming conversations you remember for a long time. He had just received his August 1996 *73* and had just finished reading my article (see page 16, *73 Amateur Radio Today*, August 1996) about Vee beams with vertical tails. He was pleased to meet an author over the ether and I was glad to meet someone who had read my article.

Acknowledgments

I want to thank my son Ethan and my wife Linda for putting up with the sticks and pieces of wire I stuck together as prototype antennas around the house.

NEVER SAY DIE

Continued from page 43

simultaneously in many different areas, all right after the passing of a comet. They then rapidly spread out, often much faster than they should have if they were just being carried by people traveling.

Here's something to think about. Twenty-five years ago S. P. Shchurin, with two colleagues at the Institute of Clinical and Experimental Medicine in Novosibirsk, Russia, placed two identical tissue cultures in sealed glass jars. They introduced a lethal virus into one of the jars which promptly destroyed the tissue colony. The second jar remained unharmed, as you would expect.

Then they repeated the experiment, but with a quartz divider between the two cultures instead of glass. Not only did the infected colony die, but so did the second colony, even though there was no way physically for the virus to get into the other sealed jar. Somehow the virus was able to go via UV light from one colony to the other. Think about the implications.

Yes, of course they repeated the experiment, and they found that when the first colony started to die that the UV radiation from it increased significantly.

It's easy to understand why our medical industry has chosen to ignore this, with no follow-up which I've ever seen reported. Check it out in *Alternative Science* by Milton. This book will have to be added to my list of books you're crazy if you don't read. It's full of stuff our scientific betters would prefer to ignore. $15 plus shipping from Park Street Press, Rochester VT 05767. Fascinating book.

DX News

I've got some permanent scars where the DX bug bit me—and a world of memories of working DX, and then being DX. Like operating from a desert island (KC4AF and KC4DX), like operating from a King's palace (JY1), like operating from the famed American Embassy in Tehran and the DMZ in Korea. Bragging? Of course I am. But more to goad you into having fun, too, than in fluffing up what's left of my tattered ego.

Anyway, I see that *The DX Bulletin* has merged with *The DX Reporter* into *59(9) DXReport*. For $36 a year (a little more outside the US) you can keep track of the DXpeditions and any unusual countries that show up. Check with Box 73, Spring Brook NY 14140. Wayne sent you.

Yes, it's a ball to work DX, and I'm looking forward to old Sol getting acne to perk things up for us. But, like any other enthusiasm, please keep DXing in perspective. When conditions are good it's easy to work 100 countries in a weekend (during a contest, natch). 200 took me a couple months. 300 took me a year. Somewhere around 340 I stopped counting. Working DX should be fun, not a dominating factor in one's life.

Almost anyone can work a station anywhere in the world if the time and bands are right, so all a big DX score proves is that you've spent one hell of a lot of time doing something of almost no consequence or redeeming value. And you know as well as I that most of your contacts over 300 countries were momentary signal reports. Piffle.

I have a secret for you. I've visited hams in well over a hundred countries and with almost no exceptions they are interested in talking with people, not in providing them with a rare QSL card. Hams in the rarer countries really hate what DXCC and the Honor Roll has done to them. It just isn't any fun to make contacts solely to fill out and send QSL cards.

But what a great feeling it is when you've made a friend in some country and then visit him in person. I loved it when VK6RU pulled out my QSL to show me. Ditto 5Z4ERR, 9N1MM, YK1AA, and a bunch of others.

Bum Tubes

You remember tubes, right? Well, if you can find replacements for bum tubes there are tons of old ham rigs which are as good as gold. Pennies on the dollar at flea markets. But, alas, getting working replacement tubes is not easy. You have to go to antiques dealers for 'em now, and that's no guarantee that what you get will work. Maybe you'd better look for a tube tester at the next flea market so you can check out the tubes you buy. I have a very frustrated letter from a reader who had endless trouble getting good tubes from an antiques dealer (not one of our advertisers, thank heavens). For my part, I'm having a lot of trouble finding a reliable replacement quenched-gap for my narrow-band spark rig.

Death Sentence or Wakeup Call?

As Andy used to say to Amos, "I'ze regusted." The more I learn about our overly expensive and monumentally ineffective medical industry, the more regusted I get. The only reason you're putting up with all their baloney is because you've been conned into trusting doctors and you haven't bothered to do your homework, despite my nagging.

And one of the best examples is the

Continued on page 48

NEVER SAY DIE

Continued from page 48

cancer industry. With there being around a 50-50 chance that you're going to have to deal with cancer personally, how long are you going to wait before you take the time to learn about it?

The cancer *industry*? You bet! It's a $40 billion industry and the insiders know the whole works is a scam. The fact is a bunch of doctors already know what causes cancer, and I mean 100% of all cancers, not just one or two flavors. They also know how any cancer can be cured—simply and inexpensively—but that would put thousands of doctors out of work and raise holy hob with the whole medical industry. Golly, I wish I were exaggerating!

And the same thing holds for AIDS, the acquired immuno-deficiency syndrome. The secret for curing AIDS lies in the name of the "disease" itself. And this also provides a powerful clue for how to treat the Big C.

Sure, we've all heard about the immune system, but it's been kept mystically buried under layers of medical jargon. So let's lay out the situation simply. We have a blood system which takes the raw materials for our body which have been processed by the lungs, stomach, liver and intestines, and distributes them to the cells so they can live and divide into more cells. The lymph system fights off the invaders, and there is no shortage of them. It also rushes to repair damage to the body. Even under the best of circumstances the immune system is kept busy handling damage repair and dealing with invaders.

So what happens when we overwhelm the immune system? It breaks down and is unable to fight off its foes as well. A strong immune system quickly detects mutant cells. In any really large factory there are always some defective products. Here we're dealing with around 75 trillion cells, all busy replicating each other from every few minutes to weeks. The immune system is a quality control supervisor, checking for defective products and destroying them. Maybe one cell out of a million will make a mistake during replication. A mutation. And if this is allowed to grow it can get out of control and you have a cancer. The body is continually generating these small potential cancers and the immune system keeps finding and destroying them.

This is the source for *all* cancers.

The immune system has been designed to cope with the level of damage which human bodies have had to deal with over the last million years or so—just as the other bodily systems are designed to work with the food, water, air, etc., which human bodies have grown used to using for fuel.

Now let's go to 1997 and the many poisons which we inflict on our bodies; poisons with which the immune system has to cope. Between immunization shots, mercury from dental fillings, chlorine and fluorides in the water, all kinds of pollutants in the air, dioxin in the water, antibiotics and hormones in our meat, pesticides on our fruits and vegetables, hefty doses of nicotine, alcohol, poisons from root canals, and so on, our immune systems are up against a barrage of enemies far beyond their design limits for coping.

And that doesn't even count the effects of stress, which alone can incapacitate even a fairly healthy immune system.

So when the immune system breaks down and cancers get started in the weaker parts of our bodies, what do doctors do? Chemotherapy! Right! They inject a new load of deadly poisons. And they radiate. It's no wonder there are so few survivors of this madness. If you look at the statistics you'll see that our trusted medical professionals have not added one day to the life of cancer patients in the last 30 years.

So what's the answer? Good grief, do you even have to ask? If you want to cure cancer (or AIDS, for that matter) you want to rebuild your immune system. This means stopping the poison input and making sure your body gets the raw materials it needs to repair itself. Clean air, distilled water, UV rays in your eyeballs, the 90 minerals, enzymes and vitamins your body was designed to use (many of which are long gone from our supermarket food shelves), and as little stress as possible. Maybe you remember Norman Cousins and his miraculous recovery just by watching comedies and reading humor books? Laugh it up. Oh yes, and exercise. Shake your cells.

Now, the choice we all have is to either continue to beat the heck out of our immune system and wait until the wakeup call comes, forcing us to either contemplate death or a change in our habits, whichever we consider less of a problem. If we choose life we have to get busy making sure we give our immune system the best break we can right now. Hmm, will it be leukemia, perhaps aggravated by EMFs? Or maybe a brain tumor (a shortage of vanadium)? I've lost some good friends to those. Or perhaps it will just be something slo-o-w and painful like arthritis.

I don't know about you, but I'm not about to wait for the Grim Reaper to take away my mike and hand me my Silent Key. So I'm eating mostly raw food, drinking plenty of distilled water, getting my exercise every day, avoiding sugar, white flour, and poisons such as aspartame (NutraSweet), adding the 90 minerals and stuff which are missing from supermarket foods to my diet, and hyperventilating every time I think of it (our air has less oxygen in it than it used to). I also laugh a lot. Hey, have you read the Dilbert book yet? And check out the humor section of my $5 (and worth $5,000) book list.

Not only am I convinced that just about anyone can regain robust health, even if near death from cancer or AIDS, but probably from almost anything else, if they give their immune system a break. But, hey, it's your body and our culture encourages a wide variety of destructive behavior. Like Big Macs and fries, or beer and Fritos. Or (sob) Haägen Dasz coffee ice cream. When your wakeup call comes, start reading the health oriented books on my recommended list and outlive your doctor.

I wonder if you know that despite billions of dollars having been spent on cancer research that no cancer incurable 25 years ago is curable today. There has been some progress with some rare types of cancer, but for over 95% of all cancer patients all that research hasn't influenced their survival one bit. Chemotherapy? No matter how many drugs or how high the dosage, it doesn't really work (Ref: *What Doctors Don't Tell You*, July 1996).

Money Is The Root

A letter from a reader read, "I think money is the downfall of our civilization." That's empty-headed blather.

Money was a great invention. It's a way to be rewarded for your skills, knowledge, and labors. Before money people traded goods or food with each other. Trading gave people access to the fruits of other people's skills, knowledge and labors. And money just makes trading simpler.

Some things are more difficult than others to make. These days an IC factory costs billions, all to provide us with very inexpensive Intel Inside™ equipment for work and play. These billions come from the pooled money of hundreds of thousands of people—pooling their labors, so to speak, to provide even better tools for us.

Money is the root all right, but not of evil. From the money root we can grow better skills, more knowledge and more productive labor. So let's not disparage money any more than we should disparage amateur radio because we have that cesspool stinking up 14,313.

NOYB

In the it's none of your business department, a reader alerted me that Lexis-Nexis has a P-Trax data base available to the public which will provide your name, current address, your previous address, your social security number, your mother's maiden name, your birthdate, and other personal information. That's a great source of information for credit card fraud, etc.

If you'd like to request that your name be deleted from this data base you can call 888-965-3947 toll free. Wait out the message about applying in writing and stay on the line for a representative. Or fax 800-470-4365. Or write Lexis-Nexis, Box 933, Dayton OH 45401.

I'm getting too old to appreciate the benefits of a big brother snitching on me. How about you?

Star Trek Nonsense

When we finally manage to invent a space drive which will get us to the stars without taking years for the trip, I hope

we'll also have developed enough smarts not to zoom into some other solar system, look for a bright blue planet, land and ask whatever life forms we find to be taken to their leaders. That's the swash-buckling way of fiction.

Reality tells us that any civilization we approach is either going to be way, way ahead of us or way behind. And I don't mean a hundred years, or even a thousand. The difference is almost inevitably going to be millions to even billions of years, and that's beyond our imagination. Even the oldest records we Earthlings have only go back a few thousand years, so we have very little data to go on as to what humans were doing 10,000 and 100,000 years ago, much less a million.

When we take an objective look at our progress in the last hundred years as compared to the last thousand, we can see the acceleration of learning. Do we think this is going to slow down or stop in the future?

No, when it comes to our dealing with a new civilization the prudent approach will be to hang around behind an outlying planet and check things out ver-r-ry cautiously. If the place looks primitive we'd then move in, perhaps behind a moon, and send down a landing party to take a closer look. At night and in a remote area.

If they're millions of years ahead of us they'll have known all about our approach early on and they'll have already contacted us. If they're millions of years behind us we might want to set up a small base on their planet and go about helping whatever life forms we find develop into something along the line of humans, using a bit of genetic engineering. We'd probably keep a small outpost there to guide their development and keep them subtly under control. If we find the planet overrun with huge beasts which could be dangerous to human-type life development, we might want to get rid of them. You know, like dinosaurs.

Now, have I fallen off my rocker again, or does that scenario make sense? If you've been doing much reading, you know that just such a scenario is not inconsistent with Earth's archeological and paleontological record. If you haven't been reading, what *have* you been doing? That 12 years of compulsory school and maybe four years of further optional time-wasting in college were only the priming of your intellectual pump. When we get out of school we are *not* educated, we only have the tools with which to educate ourselves. Alas, most people promptly throw these tools away and settle down to a life of the three Bs: bars, ballgames, and bowling. Most of the people who've worked for me down through the years have vigorously resisted any actual education once they finally got out of school. They had somehow been totally convinced that our schools had provided the only education they would ever need and no amount of reasoning could change this deeply inculcated belief.

Unless quite a bunch of pretty sharp scientists are also off their rockers, the ETs have been here for a long, long time. It doesn't make any sense that they haven't.

The Fat Life

After having spent about 40 of my years as a fat person, from about the ages of 10 to 50, I (pardon the expression) got fed up with being fat. Sure, I'd dieted and fasted all through those 40 fat years, always bouncing (oops) back to el bloato shape (250-260). When I was 50 I spent about nine months on a 1500 calorie a day regimen and dropped 85 pounds. That's about two pounds a week. I didn't want to take off the weight any faster because I was concerned that this might put an undue strain on my heart.

No, it wasn't easy. There were endless enticements to splurge, but I managed to stick at it and the fat melted away. Even better, I'd changed my eating habits enough so that once the flab was gone it stayed off. It does mean taking home larger barf bags from restaurant meals. Okay, so I get three or four meals from one restaurant dinner this way, plus plenty of exercise for my microwave.

Maybe you've noticed that there are very few fat old people. Most fatties die in their 50s and 60s, forcing the thinnies to live into their 80s and 90s in order to bring the average life span to 75. Well, that helps stave off the collapse of the social security facade. It also keeps down the queues at golf courses. Say, how old are *you*?

Hamfests

There are probably several factors which are gradually eroding hamfest attendance, and that's bad news for the health of the hobby. If amateur radio is going to

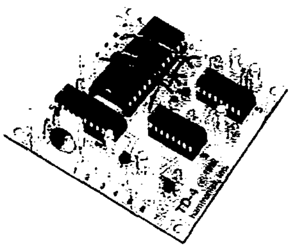
NEW PRODUCTS

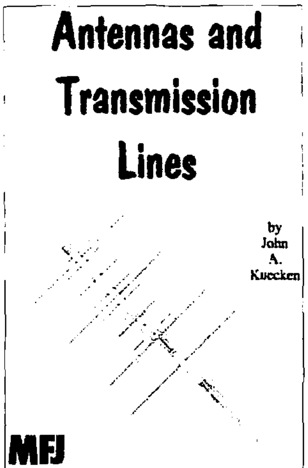
Number 50 on your Feedback card



TD-4 Selective Calling Module

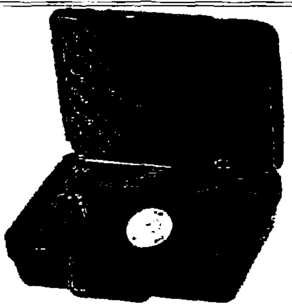
Hamtronics, Inc. recently announced its new TD-4 Selective Calling Module, an economy touch-tone decoder with one latching output. Now it's unnecessary to listen to all the activity on a channel just so someone can call you once in a while. It's easy to modify the latch input circuits on the TD-4 to perform a LiTZ (long tone zero) function for emergency use, and it can be set to turn on/off an autopatch or any other device requiring a simple ground to activate.

The 2-3/4 inch PC board is ideal for custom installations, and it operates on 12 VDC. The TD-4 is only $49 in kit form or $79 wired and tested. For more details, write to Hamtronics, Inc., 65-F Moul Rd., Hilton NY 14468-9535 or call (716) 392-9430. Ask for a catalog and tell them where you got the phone number.



Antennas and Transmission Lines, by respected author John A. Kuecken, is the newest release from MFJ Publishing. Amateur operators, technicians, engineers and students will find this book an invaluable resource. It's a handy reference guide with lots of diagrams and graphics, and direct, clear information on the theory of antennas and transmission lines.

The 37 easy-to-understand chapters deal with subjects like point array sources, standing waves, impedance matching, Q, resonant circuits, and other selected topics, such as radio-range protection. All this and lots more for only $19.95. For more information or the name of your nearest dealer, contact MFJ Enterprises, 300 Industrial Park Road, Mississippi State MS 39762; phone (601) 323-5869 or FAX (601) 323-6551. E-mail http://mfjenterprises.com; or order toll-free by calling (800) 647-1800.



The "Porta-Strip" from RF Connectors

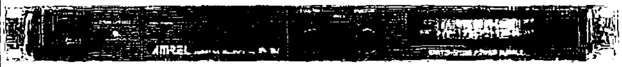
Here's the cable-stripping tool every technician's been wanting—it's perfect for professional installers, broadcast and video studios, small manufacturers and LAN installers. The RFA-4015 is small, lightweight, fast and easy to use. It's the ideal cost-effective alternative to expensive bench strippers.

The "Porta-Strip" offers quick changes with interchangeable cutter heads to fit all sizes of coaxial cable. And it comes in a slick, rugged carrying case with an AC/DC battery charger standard.

See your RF Connectors distributor, or for additional information call (800) 233-1728; E-mail: 102061.2261@compuserve.com.

Audio Transformers Catalog

SESCOM, widely known as a manufacturer of project enclosures, is proud to announce its 1997 MI-series Audio Transformers catalog for professional users. The catalog describes 59 different transformers for high quality audio applications, with technical, electrical and mechanical information. Get your free copy of this catalog by phone (800) 634-3457 (US or Canada) or (702) 565-3400. FAX (800) 551-2749 from the US and Canada (Mexico, dial 95 first); 1800-12-8491 from Australia, 0800-96-7106 from the UK; or E-mail sescom@anv.net.

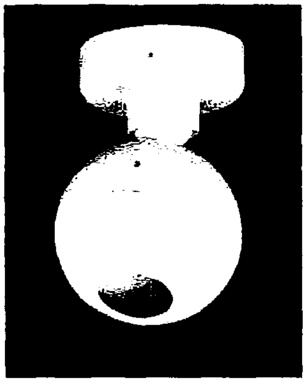


SPS Series Switch-Mode Power Supplies

Starting as low as $1,195, the SPS Series of switch-mode power supplies from AMREL/American Reliance Inc. is a no-compromise solution for your budget.

Innovative design and versatile features include: Programmable protection modes (voltage, current, temperature), fast down programming rate (1ms), low noise output (3mVrms and 30mVpp), and more.

The SPS series exceeds industry standards and offers a wide range of features for ATE, engineering, manufacturing, and scientific applications, along with a three-year warranty and toll-free technical support. For more information, contact AMREL/American Reliance Inc., 11801 Goldring Road, Arcadia CA 91006. Phone (800) 654-9838 or (818) 358-3838. E-mail: amrel@amrel.com.



Eyeball Spyball

Cool, huh? The "Smart Value" Color BC-865C from GBC ColorSentry™ is infinitely adjustable, indoors or out. You can angle the camera plus or minus 90° in any direction; look sideways or down from walls or from ceilings. The weatherproof housing means you don't have to worry about exterior installations.

The BC-865C has more than 325 lines of resolution and a sensitivity of only .4 lux. Its built-in electronic shutter and dynamic through-the-lens automatic white balance allow for true color rendition under all lighting conditions. It comes with a 6mm lens (others are optional) and a 12 VDC power module—get a high performance color ball camera for the price of black and white!

See your dealer or contact CCTV Corp., 280 Huyler Street, South Hackensack NJ 07606. Phone (800) 221-2240 or (201) 489-9595; FAX (201) 489-0111.

A Full-Time Space Shuttle Monitoring Station

Other obligations won't keep you Earthbound!

Grover C. Huckabee III K4DRF
95 Simpson Drive
Kennesaw GA 30144

It's a shame that things like making a living or family matters should interfere with our hobby—but a good ham is a well-rounded ham, and being surrounded by ham radio twenty-four hours a day is not only impossible, it's unhealthy. Still, there are things happening on the bands that would be nice to investigate, even when we must be involved in other pursuits.

Something I like to do in my shack is listen in on two-meter conversations from space. The space shuttle missions usually carry at least one licensed radio amateur, as does the Russian *Mir* Space Station. Listening to and trying to contact the Astro- and Cosmonauts is exciting, but they have limited operating time up there, and our schedules here on the ground limit us.

One way to keep in touch, even when you're not at your station, is to build a simple automatic monitoring station that will record the space side of the two-meter QSOs on audio tape. Then you can review the tapes in the quiet of the ham shack, or even in a traffic jam on the way to work. Putting together such a monitoring station can be easy and inexpensive.

You need a receiver capable of covering the frequency of interest, a carrier-operated relay, an audio cassette recorder, and a simple antenna. If you are really interested in tracking the space signals from horizon to horizon, a home-built or store-bought low noise preamplifier can be added, but it's not necessary for basic operation.

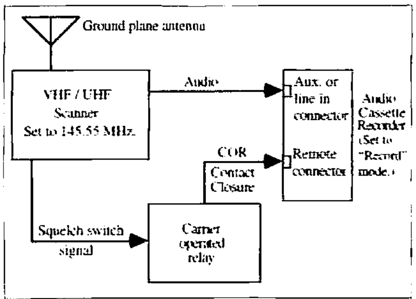

Fig. 1. Block diagram.

The heart of the system shown in **Fig. 1** is the Carrier Operated Relay. This is a simple device, and basic circuits have been described in many publications. Most applications of the COR have concentrated on its use in VHF and UHF FM repeaters, where the relay is used to turn on the repeater transmitter when the repeater receiver hears a signal. In our application, we will use the COR to turn on a tape recorder, which is listening for a signal from our receiver or scanner. A home-built ground plane or turnstile antenna, cut for the two-meter band, is connected to the antenna input of a VHF/UHF scanning receiver. The receiver I used is a Uniden Bearcat BC560XLT ($69 from a mail-order firm). The selectivity is excellent for the price, as is its sensitivity—two things to look for in a scanner. There are a couple of modifications that must be made to the scanner in order to drive the COR and the tape recorder, but most scanners are similar in construction, and a little probing with a voltmeter and/or scope should let you know where the mods must go. Basically, they consist of locating two points within the receiver and attaching two wires to bring these points *out* of the receiver and to the COR and tape recorder. The points of interest are the receiver discriminator output or squelch switch circuitry, and the audio output *before* the volume control. The discriminator of an FM receiver is the part of the circuitry which demodulates or recovers the audio from the RF signal. When there is a signal present, a positive-going voltage is usually generated in addition to the audio signal. This voltage is used to open the squelch circuit of the receiver, allowing the audio signal to be amplified and directed to the speaker. Only when an RF signal of sufficient strength is present will the squelch open and allow the audio path to function. The other factor that influences the opening of the squelch is the setting of the squelch control itself.

This control sets the threshold at which the squelch switch will open, allowing the audio path to the speaker to be completed. The tighter the squelch control is set, the more RF signal is needed to open the audio path. We can use this information to find the location of one of the wires we need to attach to make our system work, and we don't even need a schematic of the receiver to do it! We will use the fluctuating voltage that makes the squelch work to also make our COR work. The same voltage that makes the audio path of the scanner open will also be used to make our carrier operated relay close, starting our tape recording.

The only other addition necessary for a working system is to supply audio from the scanner to the audio input of the audio cassette tape recorder. Be careful to supply the recorder with audio that is always there, rather than being dependent upon the setting of the scanning receiver's volume control. Again, we will use a voltmeter to determine this point, *before* the volume control, a point where the internal audio level of the receiver is always constant. Once these two circuits are extended to the outside of the receiver, it is a simple task to make our system work.

The carrier operated relay turns on our tape recorder, to record the audio from

our scanner, once a signal is present at the discriminator. Our device will take the positive-going voltage at the discriminator or squelch switch, a voltage only present when there is a signal present at the discriminator, and convert that voltage to a contact closure for starting our audio recorder. When there is a signal present, the recorder runs, and when there is no signal the recorder stops. Also present in the COR circuit is a built-in delay that keeps the recorder running for a second or two *after* the signal disappears, so that on fading signals the recorded signal will not be choppy because of the recorder's starting and stopping rapidly. In repeater use, this circuit is usually included so that the repeater stays on between transmissions of two or more stations, so as not to overwork the mechanics of the repeater, and again to avoid the choppy audio that would result from the repeater being turned on and off rapidly, if the input signal should be weak or fading.

Putting it together

Construction of the COR (**Fig. 2**) is straightforward—it can be built on a small piece of copperclad perfboard. Layout is not critical, and neither are the parts. I chose 2N3906 and 2N3501 transistors since I had plenty of them on hand, but any switching transistors of the right polarity will do. Just make sure that the transistor chosen as the relay driver is hefty enough to dissipate the power required to run the relay continuously, since it will be turned on for long periods of time. The COR requires +12 VDC, which can be derived from the power supply that runs the scanner, or as I did it, from a separate small three-prong 12-volt regulator (7812) supply.

If you choose to run the COR from the scanner supply, make sure that the supply can handle the extra load without overheating.

R1 sets the input sensitivity to the COR. Its setting is usually not critical, but is included to allow for the variations of positive voltages available from a wide range of scanners. Q1, a 2N3906 transistor, amplifies the positive voltage from the scanner discriminator or squelch switch and delivers it to Q2, a 2N3501 transistor. This stage is used to form a delay circuit that holds the relay on, after the input signal has disappeared, for a time determined by R2. This delay time can be set from almost zero delay to several seconds. The signal is then delivered to Q3, a second 2N3501 device (the relay driver), which supplies the voltage and current necessary to close the relay. K1, the relay, can be any small 12 VDC unit.

Mods

A voltmeter is a necessity for the two modifications to the scanner (an oscilloscope is helpful, too). Most inexpensive scanners can be easily disassembled. Once that is accomplished, carefully disconnect the speaker wire plug, or better yet, position the scanner with the bottom of the PC board up, and the speaker plug still attached. This will allow you to monitor the squelch action while probing for the two mod points with your voltmeter. Find the volume potentiometer. Turn the volume up to about halfway, and open the squelch. Be sure that you are monitoring an empty channel, so you can hear nothing but noise with the squelch open. Set the voltmeter to the AC mode, lowest scale available. If you have a scope use it instead of the voltmeter to monitor the receiver audio noise. Probe each side of the volume control, while turning the volume control up and down. On one side of the volume control you should see the metered AC voltage go up and down as you move the volume control. On the other side of the volume control you should see the voltage remain constant as you turn the volume control up and down. This is where you should pick off the audio for feeding the input to the tape recorder. Make sure that when you run a wire out the rear of the scanner (to a jack or whatever) that you also run out a companion ground return. Mini-coax or shielded mike cable works well for this application.

To find the squelch switch, locate the squelch control on the front panel. Pay careful attention to how it's wired to the PC board. If you trace one side of this control you will probably see that it goes to either an integrated circuit or to a switching transistor. This control sets the threshold that determines how much signal it takes to open the squelch circuit.

Set the voltmeter to DC Volts, lowest scale, and carefully probe around the integrated circuit and switching transistor while alternately squelching and unsquelching the radio. On some pin of the IC or around the associated transistors you will find a point where the DC voltage is HI when the radio is unsquelched, and goes LO when the radio is squelched. We are looking for a point that is less than seven-tenths of a volt when the unit is squelched and more than seven-tenths of a volt when it is unsquelched. The typical swing is from near zero volts squelched to around a volt and a half when unsquelched. This is the point that should be pinned out to the rear of the radio to deliver the control voltage to the input of the COR. Again, make sure that an accompanying ground return is also delivered to the COR. Mini-coax or mike cable works well.

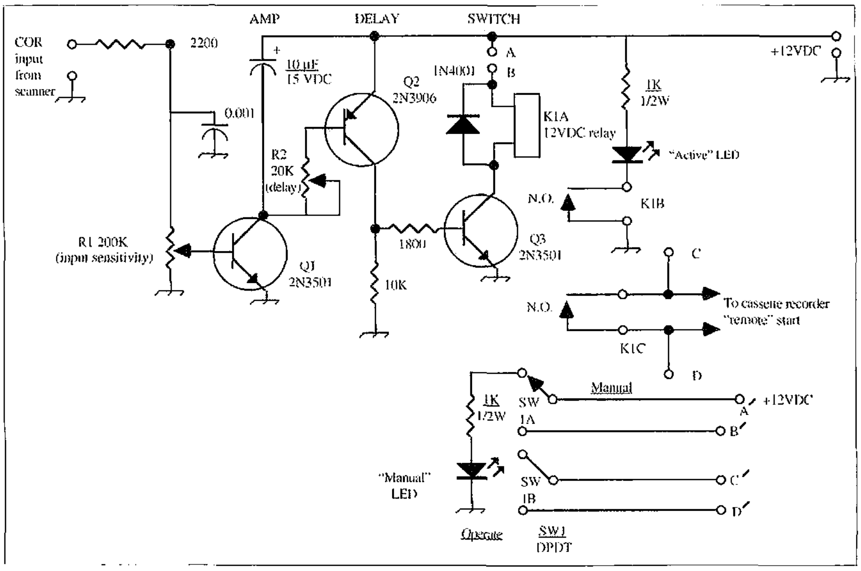

Fig. 2. COR.

Making it work

Now hook it all up and test it. Before connecting the scanner to the COR, check for short circuits with an ohmmeter across the supply voltage input and the signal input of the COR. If all looks good, then apply power. *Nothing* should happen, including smoke. Now the scanner can be mated to the COR. Turn both units off and connect the squelch switch mod output to the signal input of the COR. Turn it all on again. If it still looks good, with minimum smoke (hopefully, *no* smoke), unsquelch the radio. The "ACTIVE" LED on the COR should light, and you should hear the COR relay click. These are good signs!

If nothing happens, try adjusting R1 on the COR until something *does* happen. Leave the radio unsquelched while adjusting this control until the COR lights and you hear the relay click. Now alternately squelch and unsquelch the scanner while observing how long the LED stays lit after you have squelched the unit. Adjust R2 for a delay of at least a second and a half to two seconds. Adjustments to the COR are now complete.

Next, connect the cassette recorder to the COR and to the scanner. The output of the COR, which is the relay contact closure, should be connected to the "REMOTE" connector of the recorder. This will start your recorder when the scanner hears a signal. Make sure that the recorder control buttons have been put into the "RECORD" mode. Connect the audio mod extension from the scanner to the input of the recorder. There is usually a "LINE" or "AUX" input, on even the cheapest of portable cassette recorders. This is where the audio should be fed. If there is only an external "MIC" input, it may be necessary to make an audio pad to attenuate the audio level.

Designs for pads are available in ham publications, and consist of three or four quarter-watt resistors set between the audio source and its destination. Tune the scanner to an active repeater channel and verify that when the channel is busy, the COR "ACTIVE" LED lights, the tape machine cassette moves and that audio is being recorded (the switch on the front of the COR allows you to put the cassette recorder into a manual mode so that you may rewind and play the tape without having to pull the connection out of the "REMOTE" port each time you want to manipulate the deck).

What about antennas?

A simple ground plane antenna up about 40 feet does an acceptable job. Keep in mind that the spacecraft will be coming at you from many different angles, so a directional antenna such as a yagi will have to be constantly adjusted. If you would like to play with a better antenna than a ground plane, consider some of the turnstile designs or modified weather fax antennas described in recent ham publications.

Where are the Astronauts?

The SAREX (Shuttle Amateur Radio EXperiment) site of NASA's home page on the World Wide Web (http://spacelink.msfc.nasa.gov) will give you news about current NASA programs, activities, and even entire publications. It's an excellent way to find out about uplink/downlink changes on a particular mission. Short of that, listen in on 145.55 MHz, the worldwide FM downlink frequency, as well as the worldwide FM packet frequency.

Information on *Mir*, including predictions of when it will cross over specific worldwide cities, can be had on the Internet from the DL5KR SatTrack Prediction with modifications for WWW use by KE4AR. Just type in a key word on your favorite Web browser.

Other stuff

This system was built for monitoring manned spacecraft, but might be used for other unmanned monitoring, such as listening in on hamsats or monitoring your local two-meter net. The only limiting factor on the system is that you can only get 45 minutes of recording time per side of a cassette tape (perhaps you would like to add another timer with a loud buzzer to alert you when it's time to flip the cassette!).

Ed. note: Any modifications you make to a manufacturer's product may invalidate the warranty, so be sure of your intentions before you start your project. 73

NEVER SAY DIE

Continued from page 49

even survive we need to bring it together and get it growing again—and hamfests can be a powerful element in this mix.

Sure, I have a bunch of ideas on how hamfests can be made more fun, but only *you* know the bottom line answer to how hamfest committees can start rebuilding attendance. When is the last time you went to a hamfest? Why haven't you been to one recently? What would it take to get you to drive a hundred miles to a hamfest? Maybe even 200 miles?

What kind of activities might make you think seriously about taking a weekend off for hamfesting? Are there any ham speakers you'd drive a hundred miles to hear? How about an ARRL forum? No, I thought not. I went to one once and still haven't fully recovered. Have you got a special ham interest which might get you off dead center for a weekend: packet, satellites, emergencies, DXing, computers, certificate hunting, the ham aspects of the Internet?

Give this some thought. Hey, you might even bring it up on the air and bounce ideas around that way. Then get your word processor busy and send me a disk and hard copy. Stop making me do all the thinking. Lend a hand.

You might consider what hamfests could do to attract the no-coders, which now make up over 50% of all hams, and represent the only area of growth in the hobby. The rest of us are growing older and more crotchety, with the smokers and fatties getting their Silent Key awards from the ARRL, along with that final listing in *QST*.

And how about using hamfests as a way to get youngsters interested in the hobby? That might help bring us badly needed young blood, and thus interest a bunch of kids in getting involved with high-tech careers—something our country needs desperately.

I was 15 when I went to my first hamfest and I still remember it! Wow, I can still see that Hallicrafters Skyrider Diversity receiver, and I remember meeting McElroy, who was sitting there casually copying code at about 60 wpm while keeping up a conversation with passing hams. And one of the hams I went with (W2ECL) won the code copying contest.

What's the most fun hamfest you've ever attended? And why? Maybe we can revive the excitement that used to get us to go to hamfests.

One suggestion I've made to hamfest organizers (and in my editorials) is to offer manufacturers a forum where they would be able to explain what they've built into their newest piece of equipment. 60 years ago the features of a new receiver could be explained in a few minutes. Now, with our equipment beyond description in complexity, I'd need a half hour and a projector just to begin to explain what a new transceiver can do.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the July issue, you should send it in before the first of April. Provide a clear, concise summary of the essential details about your Special Event.

MAR 1

COMER, GA The N.E. GA "Bubba" Net Hamfest will be held 9 AM–3 PM at Madison County Fairgrounds, 1/2 mi. south of Comer, on GA Hwy. 22. Adm. $5; camping w/all hookups $6. VE Exams. Contact *James Daniel AE4HS, 152 Windfall Dr., Winterville GA 30683. Tel. (706) 742-2777.*

MAR 8

HAZARD, KY The Kentucky Mountains ARC will sponsor an Amateur Radio Hamfest at Hazard H.S. Cafeteria, Hwy. 15 South and Bulldog Rd. Time: 8 AM–2 PM. Adm. $2. Tables $3. ARRL Forum. VE Exams by WCARS; reg. 10 AM, testing 10:30 AM. Requires 2 IDs, license and copy, CSCEs, etc. For info contact *John Farler K4AVX, (606) 436-5354;* or *Sid Adams WI4M, (606) 439-3589.* Talk-in on 146.07/.67.

MAR 9

INDIANAPOLIS, IN Indiana Hamfest and Computer Show. See advertisement in Jan. *73*, page 43 or Feb. *73*, page 43.

MAR 13 & 27

FT. WORTH, TX The Lockheed ARC and the Kilocycle Club of Fort Worth will sponsor VE Exams for all classes at the Lockheed Rec. Area Facility, 2400 Bryant Irvin Rd. at 7 PM both nights. For details, call *Ted Richard AB5QU at (817) 293-6745.* G.R.D.L. testing done by appointment only.

MAR 15

LINDA, CA The Yuba Sutter ARC will sponsor a Swapmeet at the American Legion Post, 5477 Feather River Blvd. Hours are 8 AM–1 PM. Tailgate and commercial ham dealers welcome. An all-you-can-eat breakfast will be served 8 AM–10 PM. Talk-in on 146.085 (+) WD6AXM Rptr. Contact *Ron W6KJ, (916) 674-8533;* or *Clara KC6JPP, (916) 742-2674.*

MAR 15–16

MIDLAND, TX The Midland ARC will hold their annual St. Patrick's Day Hamfest 9AM–5 PM on Sat., Mar. 15th, and 8 AM–2:30 PM Sun. Mar. 16th, at the Midland County Exhibit Bldg. Inside Flea Market, Dealers, Tailgating, T-hunts and more. Pre-reg. is $7, $8 at the door. Tables are $12 ea. for the first four and $17 for each additional table. VE Exams at 1 PM on Sat. Contact the *Midland ARC, P.O. Box 4401, Midland TX 79704;* or contact *Larry Nix N5TQU* by E-mail at: *oilman@lx.net.* A registration form can be downloaded from *http://www.lx.net/edge/mid swap.htm.*

TULSA, OK The 1997 ARRL Oklahoma State Convention will be located in the Maxwell Convention Center, Downtown Tulsa, Exhibit Hall B (near the corner of West Seventh St. and South Houston Ave.) Flea Market spaces $6 in advance, $8 at the door. Limited to four. Banquet $20. Dealer booths $45 each sq. ft. VE Exams 1:30 PM Sat., and 9:30 AM Sun. Covered parking and RV hookups available. Talk-in on 145.27(-) and 443.750. Set up Fri., Mar. 14th 1 PM–10 PM. Call the Hamfest Hotline, *(918) 622-2277* voice mail/fax (24 hr.). E-mail *megriffin@ionet.net.* The Web site is *www.greencountry.com/hamfest.*

MAR 15 & 22

CLAYTON, MO The annual St. Louis County SKYWARN Severe Weather Observation Training Seminars will be held on these Saturdays: Mar. 15th, Mar. 22nd, Apr. 5th, and Apr. 12th. For locations, call the Severe Weather Info Line, *(314) 889-2857.* All are welcome including those from outside the area. No advance reg. required. Free parking. Certification provided free of charge, for R.A.C.E.S. and SKYWARN. Level 1 Training will be presented in the morning, with classes resuming in the afternoon for the SKYWARN Level 2 Program.

MAR 16

MAUMEE, OH The Toledo Mobile Radio Assn. will hold the 42nd Annual Hamfest/Computer Fair 8 AM–3 PM at the Lucas County Rec. Center, 2901 Key St. For details send SASE to *TMRA, P.O. Box 273, Toledo OH 43697-0273,* or *Paul Hanslik N8XDB, P.O. Box 273, Toledo OH 43697-0273; (419) 243-3836.*

STERLING, IL The Sterling-Rock Falls ARS 37th annual Hamfest will be held at Sterling H.S. Field House, 1608 4th Ave. There will be an indoor Flea Market, radio, electronic, computer and hobby items. Free parking, including areas to accommodate self-contained campers and self contained mobile homes. Dummy load available to test equipment. Tickets $3 advance, $4 at the door. Tables $5 without elec., $6 with. In groups of tables, the first table is $6, each additional will be $5. Bring your own cord. Set up Sat. 6 PM–9 PM, and Sun. starting at 6 AM. Doors open to the public at 7:30 AM Sun. VE Exams, walk-ins only. Bring current license, plus copy and photo ID. For advance tickets and tables, write to *Sterling-Rock Falls ARS, P.O. Box 521, Sterling IL 61081-0521;* or call *Lloyd Sherman KB9APW.AC (815) 336-2434. E-mail lsherman@essexl.com.* Make checks payable to *Sterling-Rock Falls ARS.* Talk-in on 146.25/.85 W9MEP Rptr. Advance tickets due to be received by Mar. 1st. Please send SASE.

MAR 22

WEST ORANGE, NJ A Hamfest will be sponsored by the Roseland Radio Club, 9 AM–2 PM at West Orange H.S., 600 Pleasant Valley Way. Adm. $5 at the door. XYL/Children under 12, free (with regular adm.). Reserved tables $12 for first, $9 ea. additional. $15 for first, $10 ea. additional table at the door. Reservation deadline is Mar. 15th, after that, first come, first served. Set up at 7:30 AM for sellers only. Special vendor parking lot. Talk-in on 147.415/146.415 and 146.520 simplex. For more details call *Jim Howe N2TDI,* or *Liz Howe N2WGH at (201) 402-6066.*

MAR 23

TRENTON, NJ The Delaware Valley Radio Assn. will host a Special Event at Tall Cedars of Lebanon Picnic Grove on Sawmill Rd., starting at 8 AM. Setup at 6:30 AM. Tailgating, covered spaces, ARRL Div. Official. Adm. $5, non-ham spouses and children free. 8 ft. tailgating space $10, includes one adm. Limited 8 ft. covered spaces $15, includes table and one adm. Limited electricity available. Advance reg. available. Talk-in on 146.670(-). For more info, write to *Hamcomp '97, P.O. Box 7024, West Trenton NJ 08628. Tel. (609) 882-2240.*

MAR 29

MICHIGAN CITY, IN The annual Michigan City Hamfest and Computer Flea Market will be held at Michigan City H.S., 8466 W. Pahs Rd, 8 AM–2 PM CST. Early set up provided for vendors. Adm. is $4, children under 12 are free with a paid adult. Table reservations and general info available from *Ron Stahoviak N9TPC, 5802 N 400 W., La Porte IN 46350. Tel. (219) 325-9089.*

APR 5

LONGMONT, CO The Longmont ARC will sponsor their annual Hamfest/Swapfest at the Boulder County Fairgrounds, corner of Hover and Nelson Rds., 8 AM–4 PM. Adm. $4, tables $8. Table reservations taken at *(303) 817-5526,* or write to *LARC, P.O. Box 86, Longmont CO 80502-0086.* Talk-in on 147.27. VE Exams, free parking. Contact *Jim Deeming, (303) 651-7764;* or E-mail at *jwdeeming@ compuserve.com.*

APR 5 & 6

TIMONIUM, MD The Baltimore ARC, Inc. will host their 26th Greater Baltimore Hamboree and Computerfest, and the ARRL Maryland State Convention, at the Timonium Fair Grounds. There will be a giant amateur radio, computer and electronic Flea Market, Show and Sale. Vendors, reserve early. ARRL Convention Program and Banquet, Huge outdoor Tailgate area. Indoor Tailgate area. VE Exams. Show hours are Sat., 8 AM–5 PM; Sun. 8 AM–4 PM. Adm. is $5 each day. Weekend adm. ticket is just $8 by advance sale. The show will be held in any weather. Dial *(410) HAM-FEST* for voice or FAX-back info anytime! Outside the State of Maryland, dial *1-800-426-3378.* Please make check payable to GBH&C, and mail it to them at *P.O. Box 95, Timonium MD 21094-0095.*

SPECIAL EVENT STATIONS

MAR 9–10

MILWAUKEE, WI The 1997 Wisconsin QSO Party will be held by West Allis RAC, 1800Z Mar. 9th–0100Z Mar. 10th. Modes CW and Phone. Request rules by writing to *West Allis Radio Amateur Club, WIQP Information, P.O. Box 1072, Milwaukee WI 53201.* Please remember to send an SASE.

MAR 15

MACON, GA The Macon ARC will operate W4BKM 1500 UTC–2300

UTC in conjunction with the 15th annual Cherry Blossom Festival. Phone 7.235, 14.240 and 21.335; CW 7.135, 14.035 and 21.135. For a certificate send QSL and a 9x12 SASE to *Macon ARC, P.O. Box 4862, Macon GA 31208.*

APR 5–6

PISCATAWAY, NJ The Piscataway ARC will operate their annual Special Event commemorating the Voice of America Relay station, WBOU, which operated during WWII in the Bound Brook section of Piscataway. The club station will operate under the club call K2VOA, and members of PARC will operate under their own callsigns signing/VOA. Operation will be 0000Z Apr. 5th–2400Z Apr. 6th. Suggested freqs. are: CW–Novice portions of 80, 40, 15 and 10 meter bands; RTTY–RTTY portions of the 40 and 20 meter bands; Phone–the lower third of the General portion of the bands on 75, 40, 20, 15, and the Novice portion of the 10 meter band. For a certificate, send a #10 or for unfolded, a 9x12, SASE and 2 units of first class postage, with your QSL, to *PARC, Attn: VOA, P.O. Box 1233, Piscataway NJ 08854.*

NEVER SAY DIE

Continued from page 53

I can see why the manufacturers aren't bothering to exhibit at many hamfests—there's no way to really cover a product's features and benefits in the usual minute or two a ham stops by a booth. I've attended a couple of in-depth product demonstrations and I'll tell you, by the time they're through I'm pawing the ground to buy the rig. Hey, I *want* to be sold. One of the most exciting things in our hobby is buying or building something new and putting it on the air.

Think. Write.

Speed

Are you doddering along with a 14.4 modem on the Internet while the rest of the world is running 28.8 and even 33.6? Okay Buster, then how are you doing on packet? Blazing along at 33.6 yet? D-u-u-h? Sure, on the HF bands, where you have to deal with multipath and fading, speeding up presents some interesting challenges. But up on VHF and UHF? Give me a break!

An ISDN line provides 56K, and some new fiber lines are offering 1,544K. The question is, how far are we amateurs going to lag behind commercial technology? Heck, I'm old enough to remember when hams led technology instead of trailing it by an ever-widening gap. But I also am old enough to remember the nasty fight to replace spark with CW, and stabilized rigs on 2m. Now we're seeing the fight to retain 5 wpm CW in the face of 1,544,000 bps communications systems.

I'd sure like to see some articles on faster packet systems, both for VHF and HF.

The challenges for faster packet on HF call for some creativity. Diversity systems? Spread spectrum? Multi-frequency transmitters? What'll it take? Some of our very weak signal CW techniques might help here. Bill Ashby K2TKN, where are you when we need you? And what a shame that Sam Harris W1FZJ smoked so much.

If we're not going to lose the race to the Internet we've got to get packet up to speed.

Half Our Population

What country with half our population has over three times as many licensed hams? Yep, it's the same country that's been whupping our ass in electronics ever since they took the lead in licensed hams. The latest issue of the JARL magazine runs 452 pages and it's packed with construction projects.

But most awe-inspiring for me are the hundreds of pictures (in color) of ham groups they publish every month. When I look more closely I can see that most of these hams are youngsters. This is the way amateur radio was when I got involved in the 1930s. In those days, as I recall, the average ham age was 28. No wonder 80% of us

Number 55 on your Feedback card

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)—comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

The deadline for the May 1997 classified ad section is March 12th, 1997.

Above & Beyond

Antenna Construction for VHF/UHF

C. L. Houghton WB6IGP
San Diego Microwave Group
6345 Badger Lake Ave
San Diego CA 92119
clhough@aol.com

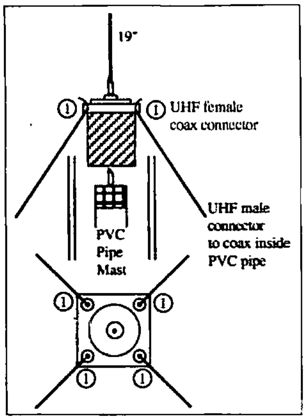

Fig. 1. Basic ground plane antenna for two meters. "1" = (4) 19" radials soldered at approximately 45° angle.

I thought that I would give some attention to simple antennas that can be constructed for our VHF/UHF bands. In a future column I will go into several other commonly-used antennas and pass on some construction techniques that I have used—but let's start out with the most basic, simple-to-construct antenna. I'll describe several methods of construction and then move on to the antenna testing vehicle, the SWR bridge that is used to adjust these antennas for optimum performance.

First let's get into some very basic structures and cover the simplest of all antennas for VHF operation—the ground plane antenna. This antenna has been the main performer for many stations, including SWL listeners in the VHF frequency ranges. The prime reason for the ground plane antenna's popularity is that it can be constructed out of common hardware store materials, at a very low cost. The basic ground plane antenna is not a gain antenna. It's a basic zero gain device.

There are several construction variations of the ground plane antenna. Let's start with the basic model. This can be built from a UHF female coax connector and five pieces of #12 electrical wire with or without the insulation. Fabricating the antenna is very simple. Cut the #12 wire to a 19-inch length for the main element and 19 1/2 inches for each of the four radial elements.

Each of the four radials is inserted into one of the four bolt holes in the UHF coax connector by bending them through and over the bolt hole. Each element is then soldered to make a firm connection to the ground portion of the connector. With the coax connector upside down (center connection pointing up), bend the four elements downward to a 45-degree angle (approximately). Then solder the fifth element (19-inch) to the top center connection of the coax connector to complete the antenna.

Keep it simple

Mounting the antenna is made simple by using a three-foot section of PVC pipe. The pipe, with the coax running through its center, is used to support the bottom section of the UHF connector. Two muffler clamps can be used to attach the PVC pipe to an antenna mast. The weight of the coax naturally holds the ground plane antenna in place. You can strengthen the #12 wire used as the vertical element by cutting a small round insulator and drilling a hole to fit the #12 wire.

Ream out a small clearance on one side of this insulator material to fit over the center connector pin of the female UHF connector. Secure in place with a silicon RTV. This short section will help to relieve strain on the solder connection of the vertical element. See **Fig. 1** for details on the basic ground plane element—the picture tells the whole story.

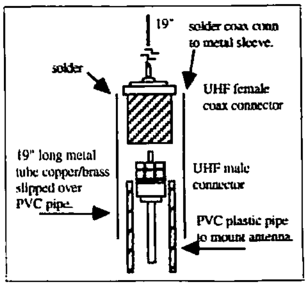

Fig. 2. Simplest two-meter ground plane sleeve design.

OK, now

You've got your antenna; you want to find out how well it matches to the frequency range at which you expected it to function. With the ground plane antenna it is almost assured that it will function well at 146 MHz. There are several methods to prove that it will function well at 146 MHz or your designed frequency.

One is to use your transmitter and an SWR bridge. This can require two people; one to operate the transmitter, and the other to adjust the antenna. Those two people could use handhelds to communicate as the antenna is trimmed for best minimum SWR on reflected power, a method that works well but may not always be convenient.

You could, alternatively, mount the antenna on a temporary test ladder over your lawn area and then adjust the length and angle of the radials for minimum SWR readings on the SWR bridge.

Another method is to purchase a commercial SWR analyzer (MFJ makes one covering 1.8 to 174 MHz, their MFJ-259). A little hand instrument replaces the transmitter and uses a internal source, which can be attached to the antenna, allowing a one-instrument test configuration to trim antennas to minimum reflection or best SWR ratio. I picked one up, and after many years of using the transmitter SWR meter method I find this instrument to be the best method available for HF through VHF.

Operation is so simple it's a snap to adjust almost any antenna to proper match—I wonder how I got along without one for so long! An added bonus is that if you make a gross error in calculations for home-brew antennas

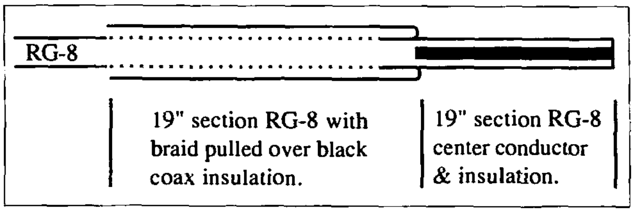

Fig. 3. *Easiest, yet most rigid, two-meter antenna to construct with minimum parts.*

and don't find a good SWR in the amateur bands, the MFJ-259 is not restricted to amateur frequencies and will tell you how far out of band your adjustment is. This makes it quite simple to know where you are resonant and what needs to be done to bring it into the amateur bands. You know right off the bat if you need to lengthen or shorten elements at your desired resonant frequency.

The basic ground plane antenna for two-meter operation works well for SWL receiving operation from 100 to 174 MHz, transmitting throughout the two-meter band with less than 1.5 to 1 SWR. Cost of construction of this antenna for two meters is about $3 and it is a very forgiving, easy-to-duplicate antenna.

The next generation

The ground plane sleeve antenna uses a metallic sleeve over the coax in place of the four radial ground elements. This metallic sleeve acts in much the same manner as the previous example's four elements and is the ground opposition to the radiating element. Electrically both antennas are quite similar even although they do not look alike.

The top or vertical element remains the same. The sleeve is soldered to the bottom side of the coax connector and is the same length as the vertical radiating element. The coax runs through the inside of the copper pipe and it is placed on a short section of PVC plastic pipe to mount the antenna. The copper pipe is connected to the same ground portion of the coax connector that the radials previously were connected to. See **Fig. 2** for details.

Going solo

The third variation of the ground plane antenna is to make the antenna out of a section of RG-8 coax by itself. This is the easiest and most quickly constructed antenna you will ever see, at least for two meters. At one end of your RG-8 cable, strip and remove about 22 to 25 inches of the outer black insulation (depending on your brand and the thickness of the insulation jacket).

I advise going long as you can always cut back on the length of braid when finished. When this length of outer insulation is removed, slowly fold back the ground braid over itself and down on over the remaining black outer insulation. It's a little tricky at first but it will go on with a little adjustment here and there.

What you want to end up with is the braid extended backwards over the insulation for a distance of 19 inches. If it's too long, cut to a 19-inch length. The center conductor and its inner insulation remain, and are also trimmed to 19 inches, for our starting point. Use the SWR bridge to adjust to precise frequency. When you have trimmed or adjusted the length of braid to your selected two-meter frequency, wrap the braid in electrical tape to hold the length adjustment you made in tuning.

If you don't tune the antenna, it will work quite well at two meters as is. Keep in mind it's not perfect—but very close. The entire antenna (modified RG-8 section) is inserted in a section of 1/2-inch PVC pipe long enough to fit the antenna and give some room to use mounting clamps below the braid. See **Fig. 3** for details.

I recommend leaving at least a foot or two of unmodified coax below the bottom of the braid before attaching mounting clamps to the PVC pipe. This helps to avoid interference from the main mast and the antenna. Use a PVC cap on top to waterproof the antenna, and on the bottom cut a small notch to allow the RG-8 to exit the side of the PVC pipe just above the bottom connector. Nothing is critical in construction or in how you run the coax through the PVC. Use any method you like to hold the cable inside the PVC pipe—after all, you don't want it to slip out.

The MFJ-259

A little horn-tooting about the MFJ-259, which I mentioned earlier. It places a small RF signal generator, with frequency counter, SWR meter, and antenna resistance meter all in one small battery-operated package. For instance, it can generate a test signal (taking the place of the transmitter), read the frequency on a internal frequency counter, indicate minimum SWR and display this frequency. It also tells you what your RF resistance is, at the RF frequency. Operation is a two-knob operation. One knob sets the frequency range and the other controls the frequency fine tuning. Simply adjust the fine-tuning knob and look for minimum SWR and 50 ohms of resistance.

This little device is quite a good adjunct for any station. I tested my unit by placing various loads and conditions of known and unknown impedances; it passed all with flying colors—and one knob/one switch operation, on the 1.8 MHz to 170 MHz frequency ranges in six bands of operation.

To test the unit for accuracy, I used several different loads, including a few very reactive complex ones, in addition to perfect terminations at 50, 75 and 100 ohms to test the resistance meter and SWR meter basic operation. Using the perfect resistance loads the SWR meter indicated near-perfect 1:1 SWR and 50 ohms RF resistance on all frequencies with the 50 ohm load. Indication was 2:1 SWR and 75 ohms RF-resistance with pure 75 ohms and 3:1 SWR and 100 ohms RF resistance

with the pure resistance of 100 ohms. Testing with proven external antennas at 7.3, 4, 14.3, 29.3, 50.1 and 146.5 MHz gave me exactly the results I had expected on six and two meters—and showed me that my inverted "V" on 80 and 40 meters was not in true resonance and RF resistance at 50 ohms.

My dipole for 10 meters was not exactly on the correct center frequency, as it was 200 kHz higher than where I wanted it—not exactly the information I wanted to hear about my existing antenna farm. I removed all the suspect antennas, performed repairs and made adjustments with the analyzer. I found a broken, half-missing ferrite core transformer (balun) and 20% of the 80 meter loading coil was shorted. I repaired the balun, rewound both 80 meter loading coils, and retested the antennas. Retesting the 80 and 40 meter antennas showed good SWR and 50 ohms RF resistance at their (previously set) proper frequencies.

Now that I have climbed back down from my roof and finished with the short antenna project that turned into a all-day repair job, I am only more convinced of the value of the MFJ-259 or at least of leaving a good SWR meter in the line at all times to spot defects. By tuning the MFJ analyzer I did not have to use a transmitter to perform tests on antenna conditions, and the portable unit worked flawlessly.

I started to verify short antennas, namely, my vast collection of "rubber duckies" for six and two meters, and found a few two meter units better suited for FAA use in the aircraft band, as they were resonant in the 120 MHz range. Pulling the black cap off the end of the antenna, removing a few coil turns, and retesting on the analyzer returned resonance to the 146 MHz frequency range. Again, I had never tested my rubber duckies, and have even interchanged them among the myriad of HTs I have owned. All I can say is that after resetting them to frequency and minimum SWR, HT operation *is* somewhat improved.

Coming up

What started out to be a simple article on two meter antennas has given me a new perspective on, and respect for, the MFJ-259 SWR bridge/signal generator. I am already thinking about some interesting additional features and sidecar attachments to make this device more useful than it already is—I will explore the possibilities further in another column. I had hoped to cover some "J" antennas and beam antenna construction for two meters and above, but I will pick that up next month.

I have started construction of a 432 beam antenna. The comparison I wish to draw is to the cost of commercial ready-to-use vs. home-brew construction. I plan to keep track of all efforts to locate materials and the costs accumulated in the beam antenna construction project. I anticipate a lot of fun in trying to convert myself, a workbench rosin addict, into a junior-grade machinist. More next month on antennas for VHF and UHF, and the dangers of the drill press. 73

Homing In Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92637

Testing N6BG's PicCon

"I need a fox!" That's one of the most common requests in my E-mail in-basket. It also shows up regularly on the Internet mailing list for radio direction finding (RDF) enthusiasts. Usually the requester has just won his first hidden transmitter hunt, which might be called a T-hunt or foxhunt, depending on where he lives. He is looking for a transmitting device because it's now his turn to hide for the next hunt.

A special "fox box" isn't always a necessity. For some hunts, all you need to do is find an unusual spot, set up a portable transmitter/antenna, and yak into the mike at intervals called for by the hunt rules. But it's more fun when you automate the process. An unattended fox (or "T") frees you to move around, drawing attention away from the transmitter's location. You can enjoy the spectacle of the hunters scurrying to locate it. It saves your voice, too. The easiest audio source for this purpose is an endless loop tape recording. Unfortunately, cassette decks don't fare well outdoors during damp evenings and they don't have provision to cycle the T on and off.

"Want to bury your T on Thursday and have it come on at hunt time on Saturday?"

Mobile T-hunts around the country have an endless variety of rules, calling for transmissions ranging from a few seconds every few minutes to continuous. On the other hand, championship on-foot foxhunts under International Amateur Radio Union (IARU) rules require several synchronized fox transmitters sending a prescribed CW message for 60 seconds each in numbered sequence.

The optimum solution for most hunts is a device with no moving parts that provides distinctive audio and versatile on/off cycling for ordinary portable and handheld transceivers. Several designs for such fox controllers have appeared in recent years, but none has been ideal for both mobile and international-rules hunts, until now.

Byon's new baby

Byon Garrabrant N6BG (formerly KD6BCH) is a software engineer and an active T-hunter (**Photo A**). He teamed up with Marty Mitchell N6ZAV to create the RaCon 6805 three years ago (see "Homing In" for July 1993). RaCon (short for Radio Controller) uses an MC68HC705C8 microcontroller IC and supporting circuits. It outputs several built-in tone sequences and timing choices plus a user-programmable sequence. CW identification is included too, of course.

RaCon became quite popular among T-hunters in Southern California, but Byon wanted something better. When PIC microcontrollers became inexpensive, he realized that one could be the brains of a fox controller that would be much smaller, cheaper, and easier on batteries. Byon chose the PIC16F84 by Microchip Technology Incorporated of Chandler, Arizona, which uses flash memory for the program and a electrically erasable PROM for data retention.

Byon polled local T-hunters for ideas for the ideal fox box. They asked for non-volatile memory, fully programmable transmit on/off timing, and a delay feature to start transmissions automatically at hunt time. The ability to change programming from a remote location during the hunt was also desirable. I suggested adding timing and CW transmissions in accordance with IARU rules for international foxhunts, plus provisions for easy synchronization of multiple foxes for championship competitions.

Before long, Byon emerged from his shop and passed out beta test kits to eight regular RDFers. Every tester met with success, only minor revisions were needed, and PicCon (pronounced "PICK-on") was born.

An easy kit

Byon says PicCon takes less than 30 minutes to assemble. He's right. There are no surface-mount parts (good!). However, you will need a fine-point soldering iron because the parts are packed onto the 1-7/8-inch by 1-3/4-inch circuit board (**Photo B**). The board is high quality, single-layer, with solder mask. All parts for the board and a RJ25 output cable are supplied. You must supply your own connectors for the mike, speaker and push-to-talk (PTT) lines of the transmitter you will be using for your hidden T.

If you're like me, it will take more than another half hour to figure out all the intricacies of programming your PicCon. The unit is so versatile that it took

Photo A. PicCon designer Byon Garrabrant N6BG likes both mobile T-hunting and international-style foxhunting. He had the best score out of 27 entrants at the 1996 West Coast VHF/UHF Conference Foxhunt.

several read-throughs of the beta test manual. (The new Version 1.0 manual is easier to understand.)

When you first activate a new PicCon, it sends a pre-programmed 3-second tone sequence over and over for 30 seconds and then identifies in CW with the software version number. Your first task is to change the CW message to your callsign and set the transmission on and off times as appropriate for your local hunts. You do this by sending DTMF commands to the fox transceiver connected to PicCon using another radio that transmits on the frequency where the fox rig is listening.

As an example, the DTMF sequence A20130 tells PicCon that tone sequences are to last for one minute and 30 seconds each. Program your callsign in a similar manner by sending numbers representing the letters and numbers in the call per the "cheat sheet" in the manual. Each command is stored into the PIC's EEPROM, so the information is not lost when the unit is powered down.

Upon application of power, PicCon waits silently. A DTMF command or push of the momentary switch on the board starts the transmission sequences. Alternately, you can program the board to begin transmitting immediately upon power up. To ensure that only you are in control of your transmitter, PicCon has a lock command. When you lock it, you enter a private numerical code that you will send to unlock it later.

Next, you can get fancy by designing your own tone sequence. You have 99 tone pitches to choose from and the sequence can have up to 28 tones before repeating. The speed of the tone sequence is programmable, as is the speed of the CW ID. You can even program a repeating 8-event series of tone sequences, off times, and IDs.

Want to bury your T on Thursday and have it come on at hunt time on Saturday? One DTMF command lets you specify a delay of up to 100 hours before the first transmission. If the hunt must end at a certain time, another command will terminate all transmissions after a pre-programmed duration.

If you use a single-band transceiver with PicCon, don't program continuous transmissions if you need remote control during the hunt. Set up at least a short receive period every few minutes. If your fox rig is a dual-band transceiver with duplex capability, you can control PicCon via one band while it transmits simultaneously on the other band.

PicCon includes a 78L05 voltage regulator and operates from a DC supply of 7 to 35 volts. It draws only 12 milliamperes, so an ordinary 9-volt alkaline battery will power it for over 24 hours. If you disable the LED via a DTMF command, current drain is only 9 mA. Even when battery voltage plummets, PicCon won't go berserk. The CMOS microcontroller is tolerant of low supply voltage. My unit worked down to 3.5 volts, though audio level diminished somewhat below 6.5 volts.

IARU mode, too

PicCon makes it easy to field up to nine foxes for radio-orienteering (ARDF) competitions. You'll need one PicCon and one transceiver for each. With a DTMF mode change command, fox #1 sends "MOE" over and over in CW. Fox #2 sends "MOI," fox #3 sends "MOS" and so forth, in accordance with IARU rules.

With other commands, you can set PicCon to send the MO sequence for 55 seconds at 5 wpm, then callsign in CW at 20 wpm, then shut off so the next fox can transmit. Program into each fox the appropriate wait time before first transmission, then start them all at once using the on-board push-buttons or a DTMF command. The foxes will cycle in perfect sequence for the duration of the hunt.

For IARU championship foxhunts on 80 meters, on/off CW is used instead of tone modulation. PicCon provides a separate 80-meter mode that keys CW transmitters via the PTT output line. There are several other useful options such as random tone sequences and rates that you can read about by downloading the latest PicCon User's Manual from Byon's Web site. Go to URL http://www.kvoa.com/byon/piccon/ or get there via the link from my "Homing In" site.

I couldn't find any faults or bugs in the PicCon hardware or firmware, but it has a few limitations. The repeater mode that was in RaCon is not in PicCon. To minimize current drain, the PTT drive transistor is small and lightly driven. You won't have any trouble keying a handie-talkie, but older mobile radios with high current PTT relays are too much load for it. So are the stamp-sized micro-Ts that have been described previously in this column. However, it's easy to solder up simple adapters with one or two transistors to key these rigs.

Byon has packed lots of features into the 1,024 words of firmware memory in the microcontroller. That didn't leave enough memory space to include error-trapping routines. If you enter an undefined command or parameters that are outside the specified range, PicCon will react in an unpredictable manner. Fortunately, there is an easy procedure to reset the EEPROM that

you can use to bail out and start over if you program yourself into a corner.

Other than listening and checking with a stopwatch, there's no way to verify the timing you have programmed with DTMF. The LED on the board flashes at various rates to indicate power turn-on initialization, DTMF being received, waiting for completion of a command, and PTT activated.

meters," he writes. "The hotel was first class. Food and drink were very cheap by our standards.

"Coffee was 25 cents and beer 40 cents in the lounge," Wally continues. "At a roadside cafe, the dearest (most expensive) item on the menu was steak and chips at one dollar US currency. The courses for the events were well selected and ranged over the undulating countryside, either open

"The only casualty was a DL (German ham) who was bitten on the leg by a farm dog."

PicCon kits are available for $49 each plus $2 for shipping/handling from Byon Garrabrant N6BG, 1150 N. Harding Street, Orange CA 92867. There is a 10% discount for purchases of three or more PicCons. Built/tested/packaged units are not available at this writing, but may be in the future. N6BG's E-mail address for inquiries is: byon@netcom.com and his phone is (714) 538-0203, evenings only.

News from Down Under

Thanks to editor Wally Watkins VK4DO for sending a copy of *Radio Sport News* from Australia. In this publication, Wally reports that the European ARDF championships in Bulgaria were a huge success. Nineteen countries took part. "The location was a ski resort in the mountains south of Sofia at an elevation of 1300

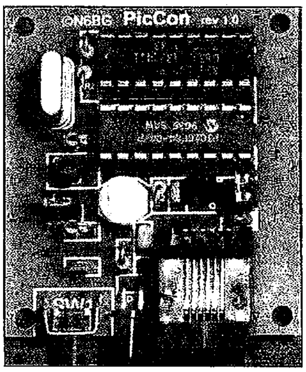

***Photo B**. This little circuit board plus a 9-volt battery and a transmitter/antenna are all you need to make a hidden transmitter for a mobile T-hunt or on-foot foxhunt.*

or heavily timbered by pine plantations. On both days, there was one steep hill to climb. The only casualty was a DL (German ham) who was bitten on the leg by a farm dog."

The first New Zealand national ARDF Championships will be March 28 through 31, 1997 in Christchurch. Separate events will be staged with 80-meter CW and two-meter AM foxes. The 1997 Friendship Radiosport Games in Kanagawa Prefecture, a suburb of Tokyo, Japan, from August 18 through 25 will include a championship radio-orienteering contest on two meters.

The next ARDF World Championships will be in Germany at St. Engelmar ski resort in the mountains near the Czech border. The World Championships after that will be held in IARU Region 3 in the year 2000. Australia is the prime candidate host country for that meet, because it could be held just before or just after the Olympic Games there.

If you are interested in attending any of these international ARDF events, write to me and I will try to put you in contact with the organizers. Send E-mail to: Homingin@aol.com or postal mail to the address at the beginning of this article. Also be sure to check the "Homing In" Web site (http://members.aol.com/homingin/) for current ARDF news. You'll also find lots of information on how to get started in both international-style on-foot foxhunting and American-style mobile T-hunting. 73

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

Satellites made easy

One visit to a satellite enthusiast's station or a look at photos of ham-radio satellite stations gives the impression that it takes a lot of gear to get on the air via the OSCARs (Orbiting Satellite Carrying Amateur Radio). In many cases it can be expensive and complex to chase the satellites. There are several that are either very high tech or use uncommon frequencies requiring specialized equipment. Fortunately there are other satellites of a simpler nature.

The Mode A (two meters up and 10 meters down) satellites like the RS series used to be the satellites of choice for beginners and portable operators. These satellites have been called "EZ-sats." All that is required is a two-meter transmitter capable of CW or SSB at a reasonable power level (10 to 25 watts) with a ground-plane

about AMRAD can be found at their Internet URL (Universal Resource Locator) http://www.amrad.org.

Launched on September 26, 1993, the satellite has performed well in its circular 800-km high orbit. It is a nine-inch cube weighing about 20 pounds with a single whip antenna for two-meter reception on top and four 70-cm downlink antennas on the bottom. While the amateur-radio segment of the satellite was designed to provide digital communications from 300 to 9600 baud, the favorite mode has been the analog FM "bent pipe."

A-O-27's "bent pipe" acts as a flying crossband FM repeater. The uplink is on 145.850 MHz with a downlink on 436.800 MHz. The repeater is usually on for daylight passes over North America. Many stations have made contacts through the transponder with simple home stations, mobile setups and even portable systems.

"Except for the antenna and the charger, everything fit in a small, soft-sided camera case."

antenna and a ten-meter receiver hooked to a dipole. A few magmount antennas even allow mobile operation.

New devices have been placed in orbit that have changed the definition of the "EZ-sat." AMRAD-OSCAR-27 (also known as EYESAT-A) is the best example.

A-O-27/Eyesat-A is based on the AMSAT (Radio Amateur Satellite Corporation) microsat design. The satellite was built by Interferometrics, Inc., as a commercial demonstration of the capabilities of a small satellite for digital store-and-forward communications. The amateur-radio portions of the satellite were built by the Amateur Radio Research and Development Corporation (AMRAD), a technology-oriented amateur radio club near Washington, DC. More information

The two-meter receiver on A-O-27 is quite sensitive. The casual user may disagree, however, based on personal observations during a typical pass. Since A-O-27 offers only one FM channel, it is like a repeater with too many users all trying to talk at once. Even weekday passes during work hours can be congested. For a low-power station using simple antennas, persistence, location and cooperation from the other users are necessary conditions to make contacts. Most of the regulars on A-O-27 are aware of the problems and try to give the newcomer or low-power operator a chance.

On vacation

I recently had the opportunity to take a week off with the family. Some great rates on a cruise

Photo A. Back on land with a Yaesu dual-band HT and Mirage dual-band amplifier for mobile/portable A-O-27 operation.

to the Caribbean, good timing, and an enthusiastic crew, kids and wife included, decided the issue.

My wife Heather WB5RMA asked if I would be taking any radios. At first I thought it would be too inconvenient on a cruise, but after listening to a talk about portable operation by Ray Soifer W2RS at the AMSAT Space Symposium in Tucson, I decided to put together a small portable satellite station. Ray used a Kenwood TH-26AT hand-held transceiver for CW uplink to RS-10 and a Sony SW-100E miniature portable shortwave receiver for the ten-meter downlink. Details on his activity can be found in the November/December 1995 issue of *The AMSAT Journal*. His article is called "The World's Smallest Satellite Station?" I started planning for an even smaller setup.

I've been on a lot of boats and offshore drilling rigs during my years in Gulf of Mexico offshore field work. I used to listen to AMSAT-OSCAR-7 with a two-meter, all-mode rig and a ground plane antenna during down time on the rigs. Once I even got a visual sighting of A-O-7 when conditions were right.

Radio frequency noise was usually not a problem for VHF reception. Although there are a lot of potential noise sources on the man-made islands, the higher frequencies are not as susceptible as the shortwave bands. Attempts to receive ten-meter satellite signals were usually not worth the trouble.

While Ray could get away from most noise sources with his simple station, I could not. The cruise ship, with its generators, lights and electric motors, could be quite a problem for my simple Grundig YB 400 shortwave receiver.

The station

To save on space and keep things light, I tried my Alinco DJ-580T dual-band HT on a good A-O-27 pass before setting sail. The downlink on 436.800 MHz FM was good, but competition on the 145.850 MHz FM uplink was fierce. A brief contact was made,

> ***"Those dual-band HTs are good for a lot more than just talking to someone on the other side of town."***

but a few station improvements were needed.

A Diamond RH778 dual-band antenna (15 inches long) was loaded in the suitcase along with an external Alinco microphone, an E.H. Yost 1000 mAh, nickel-metal hydride 12-volt battery pack (model EBP-22nh), a small wall charger, a Garmin GPS-45 receiver and some stereo ear-bud headphones. The antenna and high-voltage battery provided a better uplink signal, while the phones and microphone allowed easier orientation of the HT for best signal during a pass. Except for the antenna and the charger, everything fit in a small, soft-sided camera case.

Rather than take along a laptop computer to make predictions, I plotted out orbit listings on paper at home, based on the cruise

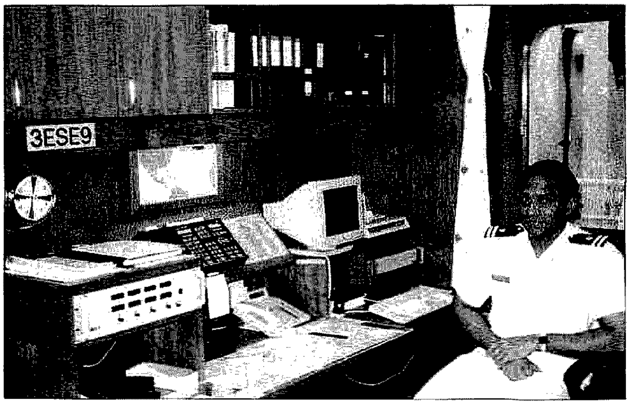

Photo B. No CW keys or spark-gap transmitters in the ship's radio room.

itinerary. Since I would not be trying to use directional antennas, prediction errors derived from approximate locations would not be a problem. Latitudes and longitudes for Miami, San Juan, St. Thomas, Sint Maarten/St. Martin and points in between were used. Only daylight passes for A-O-27 were printed.

The list was a bit short, so I included predictions for the *Mir* space station. The onboard, 70-cm repeater has been activated and available for use almost every time I have listened. Although the Doppler shift has been a challenge, downlink signals are quite readable. The repeater uplink is on 435.750 MHz FM, and the downlink is 437.950 MHz FM. A CTCSS (PL) tone of 141.3 Hz is required to access the system. More information on the *Mir* repeater and the history of ham activities on *Mir* can be found in the October 1996 "Hamsats" column.

Licensing issues

At some point it occurred to me that I might need to consider the potential legal ramifications of my maritime-mobile operation. With the exception of Sint Maarten/St. Martin, all the ports were U.S. Rather than try for a license on the Dutch/French island, I decided to be a good tourist that day, and just see the sights.

Our cruise ship, the Carnival *Sensation*, is registered in Panama, so I checked with the ship's radio operator about my potential ham activity when I got on board. After a brief explanation of what I had in mind, the operator's only concern was for my activities on land and the few HF and VHF frequencies that the ship used for port communications and emergency activity. Apparently my VHF/UHF ham activities would not be a problem. The operator was fascinated by the fact that I would be using a small HT and whip antenna to attempt satellite contacts.

Photo C. WA5ZIB on deck, getting ready for AMSAT-OSCAR-27.

The equipment in the ship's radio room included a few control panels and two personal computers. The ship's HF distress frequency was 2182 kHz and the two VHF-FM frequencies to avoid were 156.525 and 156.800 MHz. Everything else onboard used geostationary satellites. The automatically-steered satellite dishes on the ship were encased in weather radomes and were quite impressive. I was assured that there were no spark-gap transmitters or CW keys in use. Telephone rates to the U.S. were about $5.00 per minute via the satellite links.

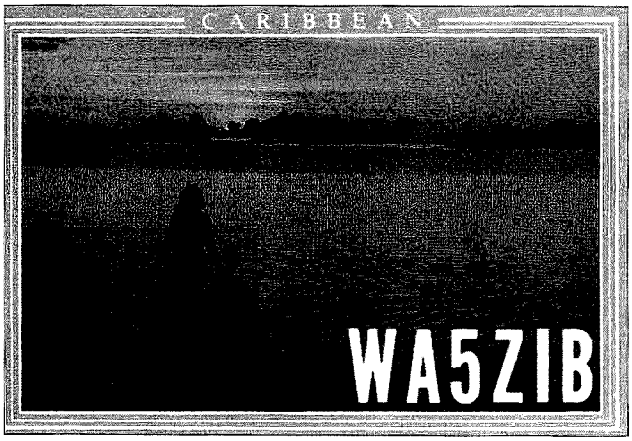

Photo D. The WA5ZIB QSL card for A-O-27 contacts made during the cruise.

The results

One of the less-populated sun decks became my "ham shack." While there were plenty of activities on board ship, there were also plenty of leisure moments. The Garmin GPS-45 receiver made a good paperweight for the orbit listings while the HT was configured for A-O-27 or *Mir* repeater operation. During the cruise several contacts were made with stations from Vermont to Texas via A-O-27. Each time I made a contact, I marked the position in the GPS (Global Positioning System) receiver. Many of the A-O-27 operators collect grid squares, and it was also a fun exercise to keep up with the ship's progress. I even had a visitor in "the shack." Frank WØAJY and his wife Nancy noticed my operation and came by to say hello and discuss ham activity and the computerized ship's radio room. While in port, family activities took priority.

I tried a few Puerto Rico and St. Thomas repeaters, but it wasn't nearly as exciting as the satellite contacts with the HT. Results with the *Mir* repeater, however, were disappointing. While I could key the repeater with the HT and short antenna, few stations were heard and no contacts were made. To properly track *Mir*, recent orbital element data is needed, and due to the 70-cm uplink and downlink, it's not possible to operate full duplex. The necessity for significant Doppler correction to stay in the repeater passband and the apparent lack of sensitivity in the repeater's receiver makes operation via this system more difficult.

Back on land

Taking satellite operation along on the family vacation turned out to be a lot of fun. I wasn't on a DXpedition and I didn't make that many contacts. It was just an entertaining experiment for those moments that would have gone to waste in front of a TV or a gaming table in the casino.

Since the cruise I have noticed other stations trying out HTs and mobile rigs on A-O-27. Many have been doing this for quite a

Letters

Internet through our home page (http://www.feist.com/~aa0of).

You can breathe a sigh of relief, Wayne, because my teaching methods would please you. My students are given numerous opportunities to experiment and discover. The basis, of course, is amateur radio, but their imaginations are free to create and design.

Wayne, the Andover Schools Amateur Radio Club would like to extend you an invitation to come and visit us. I think you'd be proud.

Hmm, maybe I'll get invited to a Wichita hamfest and have a chance to meet your students. I hope so... Wayne.

Fred Ordway KI6QK: I'm the Official Observer Coordinator for the ARRL Los Angeles Section. I believe that the OO program has been designed for failure. It is a stalling and pass the buck vehicle for the local FCC engineers-in-charge. The system fails because the FCC does not enforce the rules.

Now the ARRL in its meddling (by a radio club that represents less than 20% of amateur radio operators) is pushing its way into the regulatory process with National Repeater Coordination.

If you look at the amount of amateur radio spectrum that's available for coordination you'll see that in the three main VHF/UHF bands approximately 66% is subject to coordination.

Many of the coordination groups are made up of the Good-Old-Boy network. They started their own frequency coordination group to meet their special interests. They do not represent the amateur community and tend to protect their own self-interests. When an amateur has to pay membership to belong to a frequency coordination group to get his repeater coordinated, and only coordinated repeaters may vote for the officers and rules, it is obvious that the program is a sham.

Part 97 and specifically §97.101(b) states... "No frequency will be assigned for the exclusive use of any station." The FCC has made the regulations so that everyone can participate in the hobby. §97.205(a) says that any amateur station licensed to a holder of a Technician, General, Advanced or Extra Class operator license may be a repeater.

Now the ARRL and the frequency coordinators that are made up of repeater owners are attempting to gain a vehicle to maintain their status quo and deny or attempt to deny others full participation.

I urge everyone to study the ARRL and National Frequency Coordinators proposals to see how a private group will take away our rights and limit our participation in the hobby. This is bad for amateur radio. The ARRL must be stopped.

If coordination could be done the way GMRS repeaters are licensed, there would be no problem and no one would be denied. On the GMRS channels it is only a matter of filling out the papers and writing a check. Everyone is on the a level playing field. If the ARRL gets its way there will be no level playing field, only a continuation of a system of corruption, bribes and favoritism. If you are not in the clique, you can lose.

The band plans are established for everyone and that enables all of us to participate in the various areas from CW, weak signal, ATV, digital, SSB, FM and repeaters. This proposal will significantly diminish the level of participation of every amateur operator for the benefit of a few. I do not want to relinquish my freedom to a bunch of self-serving, self-appointed Good-Old-Boys (and -Girls).

Troublemaker... Wayne.

Carlton Davis NQ3Y. I read Marshall Emm's review of the Green Mountain 20 Meter CW QRP transceiver in the June '96 issue. The review and the low price inspired me to go out and buy one from Small Wonder Labs. The kit was easy to build, but I would not recommend it to an inexperienced builder. A beginner can probably assemble the kit with the aid of a more experienced builder. I purchased the 30 meter version. 30 meters has the long range capabilities of 20 meters and the short to medium range capabilities of 40 meters. In addition, since contesting is not allowed on 30 meters, it is easier for a QRP station to have weekend rag chews without battling the kW boys. Since I check my work as I assemble, the kit went together in three evenings. It took me

Continued on page 75

while. At my office in Houston Ken KC5WXV and I have tried a few more experiments with A-O-27 during coffee breaks. Using his Yaesu FT51R dual-band HT and a Larsen dual-band mag-mount whip antenna we could easily hear activity on A-O-27, but had marginal success getting through the FM pileup to make a QSO. We then added a Mirage DD-35 dual-band amplifier and had success. The Mirage amplifier is advertised as a full-duplex unit. When using full power output on two meters (about 45 watts), we noticed some desensing of the 70-cm downlink signal from the satellite. An AOR AR-8000 scanner on a separate antenna did not exhibit any desense, but there are some issues with the power connections and ground points that may provide some cures for the single HT/amp/antenna system.

There have been complaints about the congestion on the single channel FM transponder on A-O-27, but it's in orbit, it's sensitive and it works. While we wait for the launch of Phase 3D, there's still a lot of activity via low-earth-orbit hamsats. Plot some A-O-27 orbits and listen. Those dual-band HTs are good for a lot more than just talking to someone on the other side of town.

Communications Simplified, Part 15

Antenna basics.

Peter A. Stark K2OAW
P.O. Box 209
Mt. Kisco NY 10549

It's time to look at antennas. Although we'll look primarily at transmitting antennas, it's important to note that a good transmitting antenna will also generally work well for receiving (though not always the other way around).

The dipole antenna

Previously, we learned that a 1/4-wavelength section of transmission line that is open at the far end looks like a short at its input. Let's now take such a section of balanced line, and connect it to an RF signal generator, as at **Fig. 1a**.

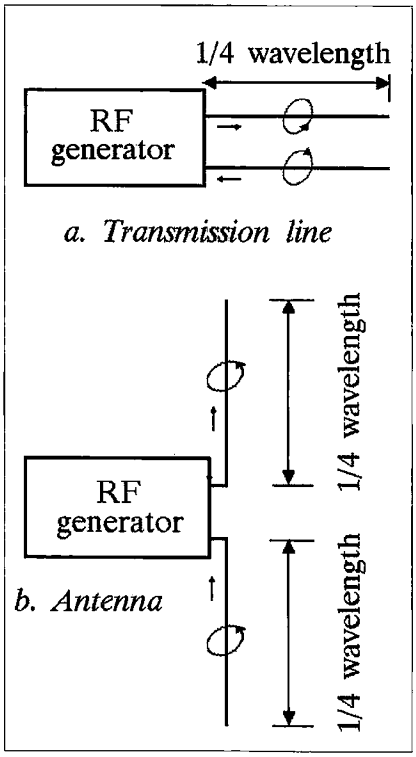

Fig. 1. A transmission line vs. an antenna.

Since the generator sees a short circuit, it is not feeding any power into the cable. That is, there is current, but no voltage; since the power is the product of current times voltage, the power leaving the generator must be zero. That makes sense, since there is no place for any power to go.

Now let's separate the two wires of the balanced line, bending them completely out so they point in opposite directions, as in **Fig. 1b**. If we now take some measurements, we will see that there is not only current flowing out of the generator, but there is also a voltage across its output. (And, for the purists among our readers, the current and voltage are in phase.) There is thus power leaving the generator and going into the wires. So where is it going?

What is happening is that, by opening up and separating the two wires, we have changed the transmission line into an antenna. The power coming out of the generator is being transmitted out into space. If we actually measured the impedance looking into the antenna of **Fig. 1b**, we would measure a resistance of about 73 ohms, rather than a short circuit. If the generator outputs the voltage V, then the power going into the antenna is

$$P = \frac{V^2}{R} = \frac{V^2}{73}$$

Look back at **Fig. 1** again. The small straight arrows along the wires show the current direction at some particular instant of time. In each case, the current on the top wire comes out of the generator, while the current in the bottom wire goes back into the generator. In the transmission line, the two currents go in opposite directions, while in the antenna, the two currents both go in the same direction—up.

These two currents both cause magnetic fields to go around the wires; these go in a circle around each wire, and are shown in **Fig. 1** as small circles, with tiny arrows indicating the direction of the magnetic field.

In the transmission line, **Fig. 1a**, the two currents go in opposite directions, and so the two magnetic fields also go in opposite directions. Moreover, the two currents are equal, so the two magnetic fields are also equal. So they cancel. That is, if you were to stand a few feet away from the wires, you couldn't measure any magnetic field because the two cancel.

In the antenna, however, the currents in the two wires always go in the same direction. Hence the magnetic fields also go in the same direction. So, if you were to stand back a few feet, you would be able to detect the magnetic fields (if you have sensitive enough equipment) because they add, rather than cancel.

In addition to generating a magnetic field, the antenna wires also generate an electric field.

DETOUR

The concept of a *field* is hard to explain, yet important for us to understand. In simple terms, a field is a system of forces filling some space, which can cause something to move. An analogy is the wind in a storm. At any particular spot, the wind has a certain strength and a direction. If you let a balloon loose at that spot, the wind will move it. How fast it moves depends on the strength of

the wind (field) at that spot, and the direction it moves depends on the direction of the wind (field) at that spot. Moreover, as it moves from one place to another, the balloon may change its motion because the field at the new location may have a different strength and direction.

The current through the wires causes a magnetic field which, at any particular spot in space, has a certain strength and a certain direction. **Fig. 1** doesn't show the strength, but the arrows on the circles show the direction. If you place a compass on the field, the arrow shows which way the compass would point.

We can also generate an electric field, in a different way. Suppose we have two metal balls, as in **Fig. 2**, and place a lot of negative charges (electrons) on the top ball, and a lot of positive charges (protons) on the bottom ball, as shown. If you now place a single electron at the spot labeled "A," that electron will move (assuming there's nothing in its way). The famous rule in electricity is that "Unlike charges attract, while like charges repel each other." The protons on the bottom ball will attract the lone electron, while the electrons on the top ball will repel it, so the electron will move down, in the direction of the arrow. So the charges on the two metal balls generate a field which can cause that electron to move.

In the same way, electron B will move down and to the left, also in the direction of the arrow, and electron C will also move in the direction shown by the arrow. The thin curved lines going through electrons B and C show the direction of that field—the path that the electron would take. We could draw an entire series of lines in **Fig. 2**, which would show the path an electron would take if dropped anywhere in the space around the two balls. These lines would then specify the direction of the field.

END OF DETOUR

So let's take another look at the antenna shown in **Fig. 3**. Imagine that the small arrows along the wires indicate the flow of electrons along the wires. Electrons flow up on the top wire, eventually generating an excess of electrons at its

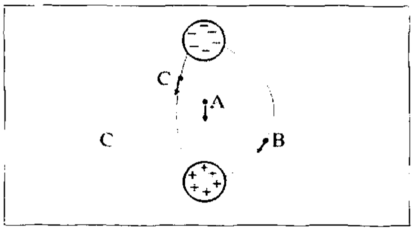

Fig. 2. An electric field.

tip. At the same time, electrons flowing upward on the lower wire leave a lack of electrons—or an extra number of protons—at the end of the bottom wire. So we now have a negative charge at the top, and a positive charge at the bottom. This generates an electric field, just as the two charged balls generated in **Fig. 2**.

At the same time, the currents in the two wires generate the magnetic field, which circles the wires as shown by the arrows on the circles around the wires.

"AM broadcast stations often float their antenna towers on a raft in the middle of a swamp, since the water in the swamp makes it a good conductor."

Remember, though, that the voltage and current are constantly changing. The generator is sending out a high frequency carrier—a high frequency sine wave with some modulation on it. So both the magnetic and electric fields are constantly increasing and decreasing, and even changing direction, as the voltage changes from positive to negative and vice versa.

The next step in our explanation requires a leap of faith; it can't be justified without a lot of math. In 1873, James Clerk Maxwell published a set of equations called (surprise!) *Maxwell's Equations*, which show that the magnetic and electric fields interact. What essentially happens is that buildup and collapse of the electric field pushes the magnetic field away from the antenna; in exactly the same way, the buildup and collapse of the magnetic field pushes the electric field outward. The result is an *electromagnetic* field which radiates outward from the antenna into space, like a radio wave. This electromagnetic wave explains not just radio and TV waves, but even light, which is just another kind of electromagnetic wave, though of much higher frequency (and shorter wavelength) than even microwaves.

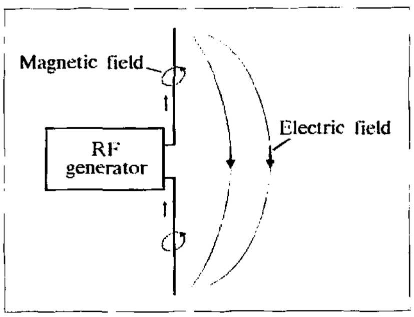

Fig. 3. Fields around a dipole.

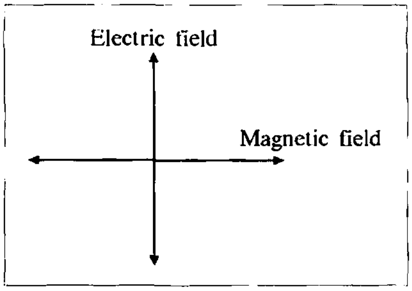

Fig. 4. Fields with vertical polarization.

In short, the two 1/4-wavelength wires in **Fig. 3** make up the simplest kind of antenna, called a *dipole*. Most dipoles, however, rather than consisting of vertical wires, are horizontal. Note that the currents in the two halves of the dipole need to be equal but opposites. The dipole therefore needs a balanced transmission line; it cannot be properly fed by a coax cable.

Antenna polarization

If you stand back from the vertical dipole antenna of **Fig. 3** and watch the electrical and magnetic fields go through space past you, because the dipole antenna goes up-down, you will note that the electric field is always up-down, while the magnetic field goes left-right, as shown in **Fig. 4**. This is called *vertical polarization*, and the antenna is *vertically polarized*. If the antenna was horizontal, then the signal would be horizontally polarized as well.

The best way to receive a vertically-polarized signal would be with another vertically-polarized antenna. The electric field will make electrons in the antenna move up and down (causing an electric current), and the magnetic field changing around the receiving antenna

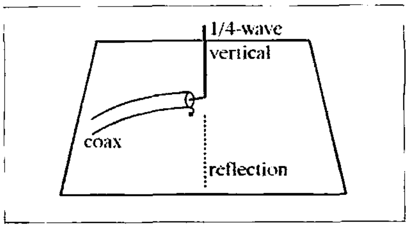

Fig. 5. The 1/4-wave vertical.

will also make electrons move up and down (also causing an electric current). If the receive antenna were horizontally polarized, then the current flow in the wire would be across the diameter of the wire, not along it, and the receiver would receive very little signal. So we need to pay some attention to the polarization of antennas. For example, most AM broadcast stations use tall towers as the antenna; these are vertical, and so a vertical antenna (like a car antenna) works well. TV stations, on the other hand, always use horizontal transmitting antennas, so you need a horizontally-polarized antenna to receive them.

Satellite communications are a problem, since satellites sometimes rotate in space, and signal polarization is also affected by traveling through the earth's atmosphere. So satellites often use *circular polarization*. This involves two antennas, one horizontal, the other vertical, positioned 1/4 wavelength behind each other, and both transmitting the same signal. The signal from the closer antenna arrives first with one kind of polarization; the signal from the other arrives 1/4 of a cycle later, but is polarized at 90 degrees from the other. So it looks as though it has turned 90 degrees. Depending on how you position the antennas, you get either right-hand or left-hand rotation.

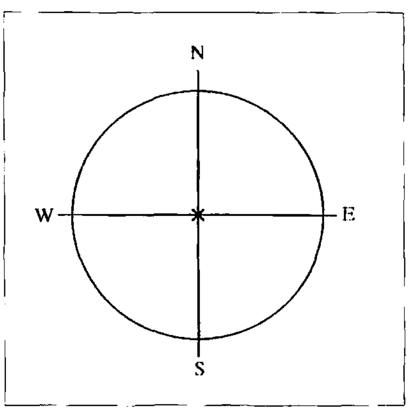

Fig. 6. Radiation pattern around a vertical dipole.

1/4-wavelength vertical antenna

A vertical antenna, such as the whip you might see on a police car, is basically half of a dipole, as shown in **Fig. 5**. Suppose you were to take just one 1/4-wavelength wire, but position it vertically above a mirror, as shown. If you then look at the wire's reflection in the mirror, you would think that there are in fact two wires—a dipole. The "mirror" under the antenna is called a *ground plane*, and it makes the vertical antenna look like a dipole.

Because radio waves reflect from a conducting surface, any large sheet of metal will act as a ground plane. So mounting a 1/4-wave whip on a metal surface, such as a car roof, works well. If a vertical antenna is mounted on the ground, it's necessary to make the ground under it more conductive so it acts as a better mirror. Commercial AM broadcast stations often float their antenna towers on a raft in the middle of a swamp, since the water in the swamp makes it a good conductor. (Incidentally, the tower doesn't actually touch the ground under it. The base of the tower sits on an insulator.) Amateur radio operators, on the other hand, often bury wires (called *radials*) in the ground around the vertical antenna. They are called radials because they spread outward from the antenna, like the radii of a circle. Radials are also needed when mounting a whip antenna on the body of a car with a Fiberglas™ body; hams often use conductive aluminum tape for that purpose.

"If you could see the three-dimensional radiation pattern, it would look like a donut."

In order to "see" a full reflection of the wire, the ground plane has to extend far enough out from the vertical antenna. It should extend at least 1/4 wavelength out in each direction, although more is better. Even so, imagine that the ground plane is, say, the length of the 1/4-wave whip. If you look at it from above, you see the reflection of the whip in the ground plane, but if you look from a shallow angle, you only see a very small part of the whip in the "mirror." Hence a vertical tends to transmit slightly upward, rather than horizontally along the ground.

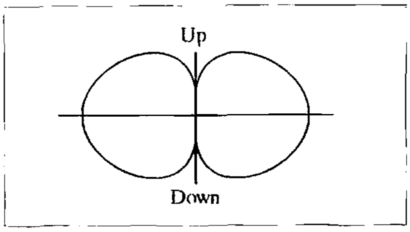

Fig. 7. Dipole vertical radiation pattern.

Since there is no bottom wire to the antenna, there is no place to connect the second wire in a balanced transmission line. Hence vertical antennas are usually fed with coax cable. The inner conductor goes to the vertical, while the outer shield connects to the ground plane just under or next to the whip. Since there is only half of a dipole, the impedance of the whip is 1/2 of the dipole's impedance, or about 37 ohms.

Radiation patterns

The term "radiation pattern" describes the directionality of an antenna. An antenna which transmits (or receives) equally in all directions is called an *isotropic antenna*. But there is no such thing—it is impossible to build one. Instead, every real antenna transmits better in some directions, and worse in others.

Consider, for example, a plain vertical dipole as shown in **Fig. 3**. You might see such an antenna, for instance, hung from a weather balloon, with the transmitter actually hanging in the middle of the antenna. Such an antenna would transmit equally well in all horizontal directions—north, south, east, and west. If you imagine that we're flying above the antenna, looking down at it, we would draw the horizontal radiation pattern as in **Fig. 6**. The small X in the middle signifies the position of the antenna, and the circle around it shows the directions in which it transmits. Because the radius of the circle is the same in all directions, the signal strength is also the same in all directions. We say that such an antenna is *omnidirectional*. (On the other hand, an ellipse which was longer north-south

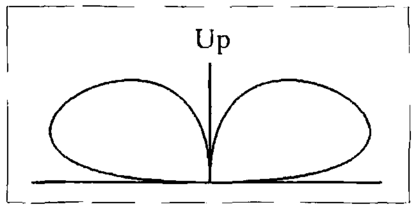

Fig. 8. 1/4-wave vertical radiation pattern.

than east-west would mean that there is more signal going north and south than east and west.)

If, on the other hand, you look at the antenna from the side, you would note that it transmits fairly well horizontally, but not at all up or down. That is because the dipole doesn't send (or receive) any signal off the ends of the wire. In this case, the vertical radiation pattern (as seen from the side) would look like the figure-8 pattern in **Fig. 7**. Since the pattern is actually three-dimensional, it looks more like a donut; what we see in **Fig. 7** is just a cut through the donut.

A 1/4-wavelength vertical antenna has the same omnidirectional horizontal radiation pattern as **Fig. 6**, but its vertical radiation pattern is more like **Fig. 8**, since it transmits slightly upward rather than straight to the sides.

Directional antennas

Although a single vertical antenna has an omnidirectional horizontal radiation pattern, it is possible to change that by using two or more vertical antennas. You may have noticed that many AM broadcast stations use more than one tower. This allows them to tailor their radiation pattern to their coverage area. If the station is on one end of a city, it may want to direct more of its power toward that city, and less to other, less-populated areas. In addition, some radio stations must reduce their transmitted power in some directions so as not to interfere with stations farther away.

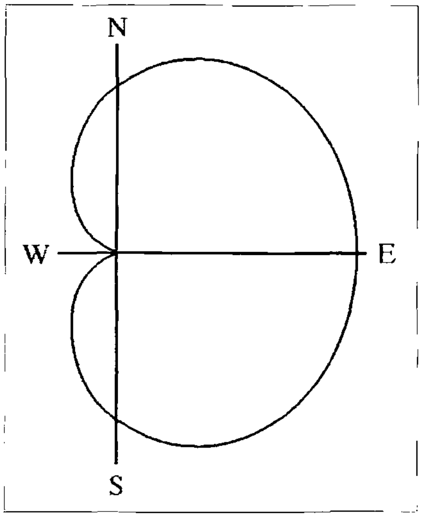

Fig. 10. Cardioid pattern from the antennas in Fig. 9.

Fig. 9 shows an example. Suppose a station has two towers, A and B, separated by 1/4 wavelength from each other, fed by two different lengths of coax cable, so that the cable to tower A is 1/4 wavelength shorter than the one to tower B.

Now imagine that you are at the far right of the drawing, east of the antennas. The signal from tower B gets to you 1/4 cycle sooner than the one from tower A (since it is closer to you), but since it had a longer cable, it was transmitted 1/4 cycle later. So the transmitted signals from the two antennas arrive at your location at the same time—in phase, and they add.

On the other hand, suppose you are at the far *left* of the drawing, west of the antennas. The signal from tower B gets to you 1/4 cycle later (since it is farther away.) It was also transmitted another 1/4 cycle later (because of the longer cable), so it arrives at your location 1/2 cycle later than the signal from tower A. The two signals are therefore out of phase, and they cancel. So the station transmits well to the east, but not to the west. The resulting radiation pattern in **Fig. 10** is called a *cardioid* because it resembles a heart shape.

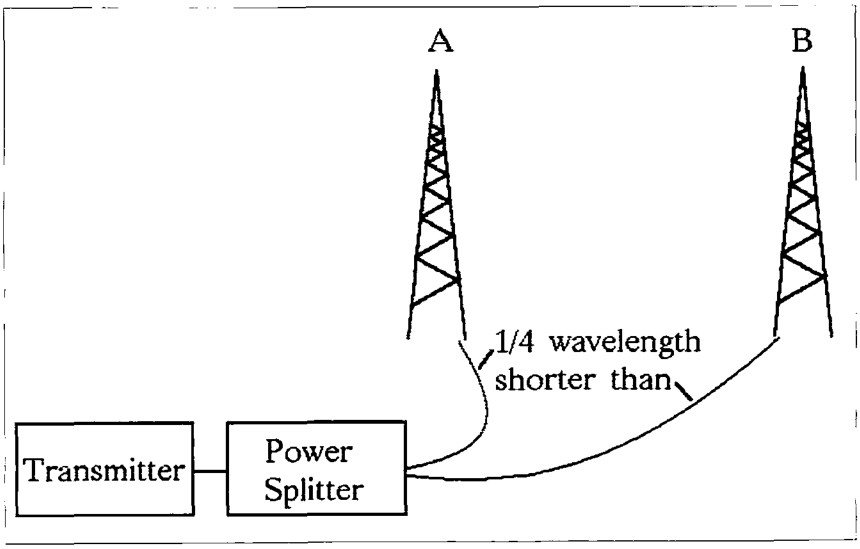

Fig. 9. Typical AM broadcast station towers.

DETOUR

The accompanying program, written in plain IBM BASIC, lets you plot the radiation patterns of various combinations of vertical antennas.

To run it, you must first specify how many vertical towers or whips there are. Then for each one you must specify where it is in relation to the transmitter (compass direction in degrees, and distance from the transmitter in wavelengths), the length of the feed cable from the transmitter (in wavelengths), and the attenuation in the cable (including any attenuation added on purpose—for example, one of the towers may purposely be getting reduced power to change the pattern).

Fig. 11 shows the radiation pattern for a two-tower setup, where one tower is 1/4 wavelength north (0 degrees) from the transmitter, and the other is 1/4 wavelength south (180 degrees). Both are fed with a cable 1/4 wavelength long, and both get equal power (assuming 0 dB loss). You see that we get a figure-8 pattern. Listeners to the east and west get the same signal from both towers, so the two signals add. Listeners north and south, however, get the two signals 1/2 cycle apart (because one tower is 1/2 wavelength closer than the other) and so the two signals cancel. You can experiment with different combinations in the program.

END OF DETOUR

The above examples were all based on AM broadcast station towers; in that case, the towers are actually fed from the transmitter through some sort of a matching network. It is possible, however, to build a directional antenna without actually supplying power to the other components. **Fig. 12** shows how; it's a

beam antenna, also often called a yagi antenna. In the center we have a boom, which holds a number of elements. One of these, connected to the transmitter by the feedline, is called the *driven element* because it is actually driven by the transmitter signal. It essentially acts as a dipole.

Mounted parallel to the driven element are one or more *parasitic elements*, which are not directly connected to the transmitter. There is usually one *reflector*, and one or more *directors*. Each one of these parasitic elements acts as a separate little antenna.

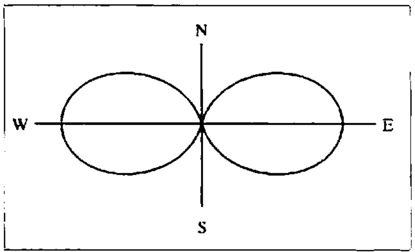

Fig. 11. A figure-8 pattern from two towers.

A normal dipole consists of two 1/4-wavelength pieces, connected to a transmission line. Suppose, however, that the transmission line was missing, and instead the two sections of the dipole were shorted together in the middle. Any signal received by the dipole would go to the middle, hit the short, be totally reflected back into the dipole, and then be retransmitted into the air. This is precisely what the reflector and directors do—since they are so close to the driven element, they pick up a small amount of signal, don't know what to do with it, and so they send it right back out again. The signals transmitted by the driven element, and retransmitted by the parasitic elements, then add or subtract to make the overall antenna directional.

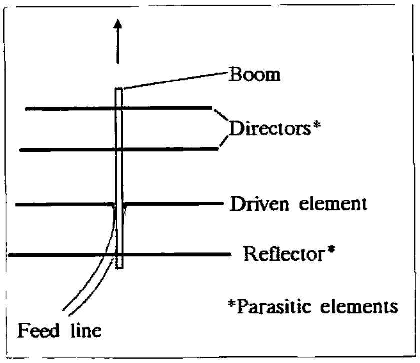

Fig. 12. A 4-element yagi beam.

Looking at **Fig. 12**, you'll note that the reflector is slightly longer than the driven element, while the directors are slightly shorter. The different lengths change the phase angles of the preflected signals to make sure that the signal is sent in the correct direction. The reflector reflects the signal, whereas the directors act as a lens to direct the signal forward. The arrow in **Fig. 12** is at the front of the antenna—it shows the direction where most of the signal goes (the other end is obviously called the back).

Fig. 13 shows the radiation pattern of a typical yagi; we assume that the antenna is aimed north in this case. We see four lobes: one *major lobe* which shows that most of the power goes north, and three *minor lobes* which show other directions where some of the other power goes. Between these lobes are directions which get no power; these are called *nulls*.

The length of a lobe represents the gain of the antenna in that direction. We will define the gain of an antenna next time; for now, let's just note that the gain of this antenna in the forward or front direction (toward the directors) is higher than the gain in the back direction (toward the reflector). The ratio of these two gains is called the *front-to-back ratio* and it is usually expressed in decibels.

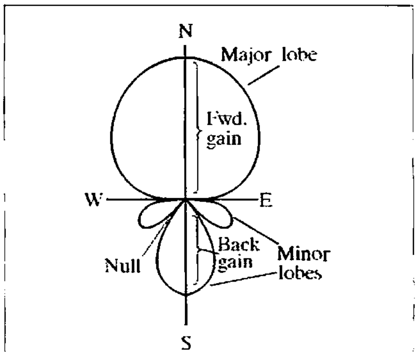

Fig. 13. Radiation pattern of a yagi.

NEVER SAY DIE

Continued from page 55

were able to join the military in World War II. When I went all around Brooklyn on my roller skates, visiting the hams listed in the Callbook, I found that virtually all were active, and almost all were in their teens or 20s.

Today, being generous, maybe one in four American licensees is active, while in Japan almost all of their hams are active. For me this explains why, though we have almost three times as many licensees as we did 30 years ago, the ham bands don't sound any more crowded.

What would our bands be like if we had five million hams? Five million *active* hams? It sure would put the pressure on our developing more efficient communications systems. We'd also be far more active in our microwave bands. The JARL magazine devotes a half page to 10 GHz activity! Here, other than as a way to pick up a few extra multipliers in a VHF contest, what activity are we seeing on the band? Yawn.

With 5 million American hams—young hams—the danger of losing our bands would evaporate, and we might even generate enough high-tech career youngsters to regain our lost electronics industries.

If you're interested in helping do something about this situation let me know.

Intruders

You're probably not going to believe this, but I have it on good authority that several hams are selling ham gear for pirate use, and in most cases the buyers aren't even being made aware that they are doing anything wrong. This has to do with 420 MHz ATV transmitters used being used for surveillance. Some ads even claim that the equipment has a range of 50 miles, with the really small print explaining that this requires the use of yagis, though it doesn't explain that the yagis required are huge antennas, and not well suited to hidden TV surveillance work.

Further, both the ARRL and the FCC have been made well aware of all this problem, but neither seems to care.

Since there's so little actual ham activity on our UHF bands they are wide open for illegal commercial uses.

Is this all a matter of crooked hams doing this? No: As I understand it, Ham Radio Outlet™ got taken to court for refusing to sell a ham rig to a non-ham. And lost.

NEW PRODUCTS . . .

WASSCO Announces New Free Catalog

The new 148-page WASSCO catalog is chockful of great doodads, gizmos and stuff for the electronics professional. There are tools and equipment for soldering, testing, static control—you name it! New products from Chemtronics™ are featured, as well as Plato™ shears and Weller™ fume extractors. These fume extractors reduce harmful soldering emissions by 99.99%—before they can be released into the environment.

For your free catalog, write WASSCO at 12778 Brookprinter Place, Poway CA 92064. Phone (800) 492-7726 or (619) 679-8787; FAX (619) 679-8909, or visit the Web site at http://wassco.com.

Great ARRL Books!

AR1086-4 **ARRL Operating Manual** Information on how to make the best use of your station, including interfacing with home computers, OSCAR, UHF-VHF. $22.00

AR4173 **Now You're Talking! All You Need To Get Your First Ham Radio License**–A complete study guide for the Technician and Novice written exam. Practical information every beginner needs is written clearly and simply and in small doses. $19.00

AR4734 **ARRL Antenna Book**. Best and most highly regarded info on antenna fundamentals, transmission lines, design, and construction of wire antennas. $30.00

AR0402 **Solid State Design** Good basic information, circuit designs and applications; descriptions of receivers, transmitters, power supplies, and test equipment $15.00

AR3177 **ARRL Spread Spectrum Source Book** From a deceptively simple beginning, a group of experimenters set out to develop first theoretical and later practical systems for spread spectrum communications. This book consists of articles, papers and government reports that document the process whereby amateur spread spectrum progressed from the drawing board to the airwaves. $20.00

AR4661 **ARRL's Antennas & Techniques for Low-Band DXing** can be your ticket to low-band success. $20.00

New Product reviews and reviewers are welcome. Write Joyce Sawtelle at 73.

Optimizing the Hamfest Experience

The next hamfest flea market you surf can be even more rewarding.

Ronald Lumachi WB2CQM
73 Bay 26th Street
Brooklyn NY 11214-3905
E-mail: wb2cqm@juno.com

No one can deny that certain individuals experience pleasure when they visit a flea market, shell out some bucks for an item, and subsequently display their bargains with great pride. Sometimes it's just junk, but who will argue the truism that beauty is always in the eye of the beholder? The same phenomenon holds true for the hamfest participant who plans to visit an event that some (even my wife) have characterized as organized chaos. Perhaps, but there are redeeming qualities. In order not to be overwhelmed by the size and complexity of the activity, it's a good idea to know what to expect and to develop a plan that will ensure that if one attends a hamfest, one's efforts will be rewarded.

For the first-time "hamfester," the primary order of business is to check the newly arrived issues of *73* and other radio-amateur–related publications for the listings of area hamfests. The dates are published well in advance of the event. You will probably have developed a long list of wants, since few retail sales outlets exist to offer the specialty components required to complete that unique project.

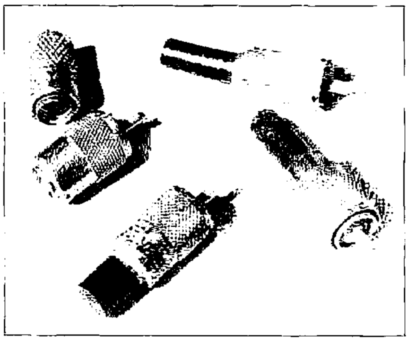

Photo A. PL259s with short cut-off lengths of 8u cable attached. 25¢ each.

If the event is not local, you may consider car pooling or traveling with friends or radio club members to save money. It takes some planning to coordinate this activity, especially if a group is involved. I've found that the trip's logistics are the least complicated aspect of this adventure. Once you've struggled through the nightmare of getting four or five hams to agree on a single travel strategy, the remaining details are difficult but not impossible to resolve. At worst, it may result in a migraine or a bit of indigestion, but the obstacles are surmountable.

"As a veteran of many hamfests in the northeastern areas, I have developed a strategy for getting the most out of this activity."

As you arrive at the parking area, it will become abundantly clear that you're in the right place. You'll be greeted by a veritable sea of mobile antennas and a host of callsign license plates. Just about now you'll begin to wonder where all these people came from—they're seldom seen during the year. It has been my experience that only on rare occasions will you encounter a ham when driving. In any event, try to park close to the entrance so shuttling back and forth with purchases is not a marathon run.

Where to begin?

Techniques for maximizing the positive experiences of participating in a hamfest visit begin when you arrive at the gate. It's amazing, but no matter what time you get to the entrance, there's always a bunch of hams queued up and chafing at the bit to get inside. You'll see an array of people, including spouses, XYLs and children, bustling about anxious to double-time the area, on the alert for that elusive bargain. They're easy to recognize. The vast majority of them are sporting baseball caps emblazoned with names and callsigns. Handhelds are either strapped to their belts or stuffed in breast pockets. The conversation is lively but the hamfesters are focused on two things: They've got one eye on their WWV coordinated watches, while the other scans for any initial movement through the entrance gate. Getting past that obstacle with the minimum of delay is top priority at this point.

Here's the dope!

As a veteran of many hamfests in the New York City, Connecticut, New Jersey, Maryland, and Pennsylvania areas, I have developed a strategy for getting the

most out of this activity. It's been refined and tuned and works well for me; I am certain that it's worth a try on your part. Primarily, I'm addressing those who are looking for particular pieces of equipment, or who perhaps need to acquire a discrete component to repair or complete a piece of gear. If, on the other hand, you're just out for an interesting and pleasurable day (with no particular motives for the visit), just go, browse, and enjoy. You'll be in the company of thousands of hams, each with a unique agenda for the day.

Oddly enough, you'll begin what will be a most enjoyable and rewarding amateur radio experience by paying your entrance fee at the gate. If you begrudge them that token amount, keep in mind that it's a pittance for so many hours of fun. If you had to pay even minimum wage to the tireless army of volunteers and coordinators of the event, the price could easily be tenfold. You'll save time

"Socializing ends as you pass the main gate."

if you have the correct dollar amount handy. The fee is usually listed in magazines and newsletters, along with other important information related to the event.

It's always a good idea to get there as early as possible. You'll find that almost everyone in attendance has the same game plan; it must be intuitive with hams. They know very well that high interest items go quickly so you've got to be Johnny-on-the-spot.

Once you're through the gate, dispense with the preliminaries as quickly as possible by filling out your door prize ticket stub and depositing it in the appropriate container. Bring a pen (and pad) with you in order to avoid the crowd jockeying for the writing implements tied to the ends of strings at the sign-in table. You'll find 50 hams waiting to use a couple of pencils. Don't forget to complete this chore, and determine whether you must be present for the grand prize drawing. During the course of the day, stubs are pulled and winners of prizes are announced via loudspeaker. During your visit, remember to keep an ear open for the announcements of the lucky ones. Somebody's got to win the door prize and it might be you!

Focus clearly on your objectives

Socializing ends as you pass the main gate. Save that for later when you'll need to make a pit stop or break for lunch! I would strongly suggest that you travel alone from here on in. If you need any counseling from your Elmer regarding a purchase, keep a handheld strapped to your belt and prearrange the monitoring of an odd simplex frequency to call for a rendezvous. If you're in pairs or small groups, time will be wasted as you wait for the gang to reassemble and move on after visiting each vendor. It's vital that you first transit the entire area quickly, especially if you're looking for items that are not generally offered by a slew of vendors. It's those dead-special, one-of-a-kind deals that you want to scoop up as quickly as possible. Do not hesitate to negotiate; there's no law that says you must pay the sticker price. Make reasonable counteroffers but avoid denigrating or otherwise badmouthing the item. Be aware that the seller usually has a good idea of the ballpark value of the component so compromise is an essential element in the process. If you're successful in locating that dead-special piece of gear and you're close in the price negotiations, I suggest you buy it. You'll kick yourself doubly hard if you return and it's gone. That has happened to me on too many occasions. I've reasoned afterwards that spending the extra dollar or two would have been worthwhile to eliminate the grief of continuing the search for an item that I may never again find.

Strategies are somewhat different for the more readily available items offered by larger numbers of vendors. As you continue your reconnaissance, use your

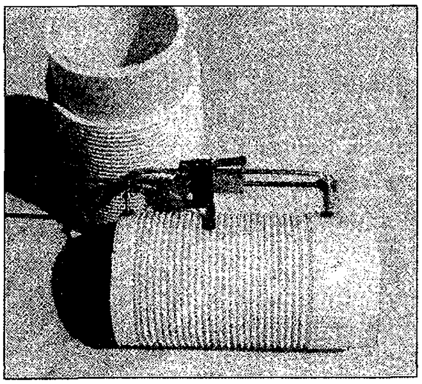

Photo B. The author's plan for a remotely tunable coil wound on a length of 3–4-inch PVC.

notebook to jot down prices and vendor locations. For example, don't buy microphone connectors from the first person you approach. These items are extensively offered and the prices may vary by 30–40%. Obviously, you want the best deal you can get. Continue your first sweep of the hamfest without any undue delay. Make whatever notations you need in order to quickly return to the vendor who's offering the best deal.

Keep in mind that some hamfests are enormous in scope. Generally aisles and rows are not identified or marked. It's easy to become disoriented and often difficult to return to a vendor quickly if at all. Latitude/longitude of GPS bearings don't work well here. Preferably, use cruder but more realistic location reminders, e.g., mid-aisle two rows from hot dog stand, or main building—rear wall. I'm certain you get the idea.

Avoid chatting during this first run. Check your want list to make certain you haven't forgotten anything of importance. If you've offered to pick up an item for a friend, make that your secondary effort. It's OK to be somewhat selfish at this point. If your pal wanted the item badly enough, he would have come himself.

During that first pass, keep a watchful eye on the equipment and components offered by the "tailgaters." These are the individuals who are cleaning out basements and shacks and lightening up on their junk box inventory. Bargains are available simply because many spouses have decreed that the beleaguered amateur may not return home until all that junk is dumped.

Here are the ingredients that make for mutually rewarding transactions. However, be a gentleman—make reasonable offers and avoid nasty confrontations. If your offer is refused, ask if and when you return whether a counteroffer would be entertained. By using this tactic, you've left the transaction open-ended rather than putting closure on what could be by this time a dead deal. Again, if you're close on the price, don't take a chance on losing out on the purchase opportunity.

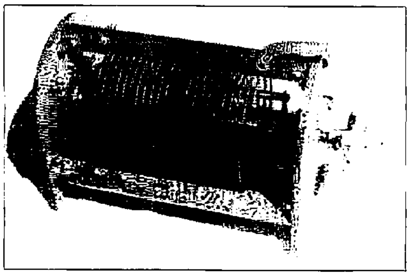

Photo C. A bargain variable inductor.

The second and third round

Once you've completed the first round, it's time to check your notes and revisit only those vendors you identified as having the best prices. Pick up your coax connectors, meters, circuit board components, power supply diodes, jumper cables, etc., and don't hesitate to ask for a special volume price. For example, you may work a deal for a dozen PL-259s for $7 rather than buying them singly or in pairs for 75¢ to 80¢ each. Certain items will always be used in the shack. Even though the up-front price may be a little more, you'll have the component when it's needed. The same holds true for volume purchases of bypass capacitors or mini 12 VDC DPDT relays, but not necessarily for a bushelful of 8-pin mike connectors or a gross of tube sockets. A bargain is a bargain only if it has utility.

Take a break at this point and bring the collected goodies out to the car. Remember: You'll need your ticket stub or hand stamp for re-entry. There's no need to lug around a bunch of plastic bags filled to the brim. Enjoy a snack and drink from the cooler you remembered to stock earlier that morning. Briefly relax and don't hesitate to reflect on the good deals you made. The day's important business being completed, it's now time for the fun part of the outing. Hopefully you have the energy, especially if it's been a hot summer afternoon. During the third, but leisurely, walk around visit the vendors with the interesting items that require more careful scrutiny. It's also the opportune time to return to those vendors who encouraged a return visit for further negotiations. You'll remember you didn't burn any bridges when there was no agreement on price for a particular item that piqued your interest. By this time, the crowds will have thinned and the frenzied feeding abated. Take some time to look through boxes for any special items of interest. Use your imagination to envision how a piece of esoteric equipment could be purchased for peanuts and utilized for a worthwhile project. I recall I once purchased the hand portion of a fighter pilot's steering control. It was a molded hand grip with a series of switches to control airplane functions (guns, etc.). If you've seen any of the World War II movies, there's always a close-up shot of this grip just as the pilot, with the enemy in sight, squeezes the trigger and the guns begin blazing away. In my application, the unit was mounted on an old wooden trophy base with a D-104 lollipop mike attached at the top. It was wired using the trigger to activate the push-to-talk circuit. I didn't shoot down any planes but I did make a few interesting DX contacts.

If on your third round trip you notice that an item you wanted is still available, spend some time with that vendor. Be honest and express your interest but suggest that the price may be unrealistic. Most probably, the seller has come to the same realization as evidenced by the fact that it didn't sell. Ask politely if he has some "room to move" on the offering price and subtly suggest that it will have to be lugged home and only brought back for the next hamfest. At this point, an Academy Award-quality performance may help. Whatever tactics you use, remember to be persistent in a dignified manner, and if you're at an impasse, suggest splitting the difference between the bid and asked price. If a deal can't be struck, leave your name and address (E-mail, etc.) in the event the vendor might reconsider. You might even take his card or telephone number and ask if you could call at some time in the not-too-distant future and check on the disposition of the component and whether the asking price has been moderated. It makes good sense to keep the dealing friendly since there is always that possibility that your paths will cross again and the deal will come to fruition.

Caveat emptor!

Purchasing electronic items at a hamfest is a ticklish issue that requires a more heightened awareness of the potential for a bad deal. Let's address the easy ones first. If the item you are considering needs a battery or AC power to operate and evaluate, take the time for a test. The condition of a keyer or a low voltage power supply is also easy to verify. There's always an outlet around

for a quick check. If it's sold *as is* then the price should be commensurate with the risk of possible damage. Agree on the terms of the transaction and make certain to take the dealer's card. Have him jot down the particulars of the sale including serial numbers and have him list the alternatives for refund or replacement if it's lugged home and it goes up in smoke or is simply inoperative. For example, it's almost impossible to test the 2 kW scale of an SWR bridge at a hamfest so it's important that you do your best to protect the cost of your investment. You'll want to know if it can be returned for refund or replacement and who will pay the cost of shipping. Do the same thing even though the component is in a sealed carton and includes a warranty. You'll need a bill of sale if it's returned to the manufacturer under normal procedures. If the vendor is reluctant to agree to reasonable terms (which is not often the case), simply say NO to the deal and walk. An intransigent dealer unwilling to offer reasonable assurance about a product may be signaling that an underlying problem exists. You don't need the grief so pass it by and wait for the next opportunity. For the purchase of any large-ticket item, it's a good idea to bring cash. Nothing works better in eyeball-to-eyeball encounters than the sight of the green stuff. Forget about checks. Remember the adage that money talks and everything else walks!

It's a learning process, too

Let's not forget another dimension of hamfesting, one that I find most interesting. After completing the regular order of business as outlined, you may want to stop and chat with some of those special participants who are clearly recognizable because of the equipment they are selling or the quality of the wares they are offering. For example, I recall a discussion with a gentleman offering homebrew tank circuits with integral band switching for 160–10 meters. He had cloned, with some modifications, a unit which had been available commercially a number of years ago. I had been working on a similar project and recognized the fact that we were indeed, because of our common interests, kindred spirits. Our discussions covered inductance measurements, impedance, and circuit *Q*. We were both concerned about the changing tank circuit electrical characteristics in older linear amplifiers when re-tubing with newer and more efficient finals. We were both aware of the fact that increased voltages cause strange things to happen as power is raised to accommodate the updated designs. I also mentioned that I planned an article discussing silver-plating homebrew wound coils. He'd already made the calculations and determined that the impedance change was only a fraction of a percent on the low bands and probably not worth the effort. It gave me food for thought about embarking on what might be just a fool's mission. He very much appreciated my comments on the quality of his efforts; however, when I asked how many of the units he sold, the answer was "none." So much for good old-fashioned linear amplifier building in this current day and age. Although I did not purchase any of the items he had for sale, for both of us it was one of the highlights of that afternoon.

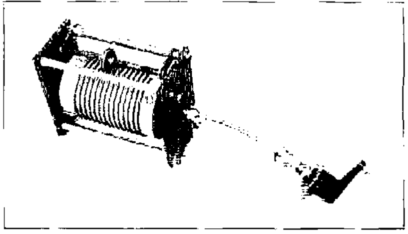

Photo D. A small variable inductor coil and flexible shaft just waiting to be stripped down and reconfigured.

Noteworthy hamfest bargains

Keep a watchful eye open for bargains. For example (**Photo A**), PL259s with short cut-off lengths of 8u cable attached were offered at 25¢ each. Clean plugs were 85¢. I opted for the less expensive units. Removing the coax occupied me as I monitored the Traders' Net and waited my turn to list. I bought all he had and received an additional bargain for the volume purchase. I've already removed the coax on two of the plugs.

I have been experimenting winding coils on PVC tubing for 160–80m applications. Coils are expensive (especially variable inductors) when purchased commercially. My plan was to design a remotely tunable coil wound on a length of 3–4-inch PVC. The plan included utilizing a 10 amp relay contact riding along a length of threaded rod to vary inductance (see **Photo B**). It was evident from the partially completed prototype that it would be great for receiving but only marginal for transmitting other than low power. During a recent hamfest visit, I spotted the variable inductor shown in **Photo C** on a vendor's table. I swooped in on my second turn around and negotiated—I paid $40 and saved 33% in the bargain. Contrast this with the purchase of a plain old 3-inch air-wound coil offered in the classifieds at $45. The inductor has no marking but is easily rated at 10 kW and can be used as a tank circuit component in an RF deck, an antenna tuner or, for my immediate needs, a most vital element in my remotely tunable base loaded inverted "L" for 160–80 meter operation.

See **Photo D**. This small variable inductor coil and flexible shaft has a wealth of parts just waiting to be stripped down and refitted in an alternative configuration. Both the support and roller shaft must be lengthened to accommodate a longer coil form. Since both shafts are tapped at the ends, that presents no problem. Larger vertical supports will be fashioned from plastic and the pilot shaft bearing from the old unit reinstalled. I'll add small pieces of metal to lengthen the coil supports and shaft to accommodate the larger diameter inductor. The flexible shaft and crank are great additions to any number of projects. This was truly a great bargain at $7.00.

Photo E shows a DP3T. This well-designed and heavily-built ceramic RF switch (75¢) was purchased for a contemplated project to control the input from an exciter to two linears. The porcelain shaft insulator pictured to the left was included in the deal. A couple of bargain hamfest SO-239s and a minibox is all that is needed to complete the project. One of the poles will be tied together with a wire bus and one position locked out. The result will be a silver-plated SPDT coaxial switching unit with a 2 kW+ rating, and a savings of a bunch of dollars over a commercially-built component of lesser quality.

Keep on the lookout for switches with a greater number of contacts (**Photo F**). They can be used on the output end of your transceiver or

Photo E. Another hamfest bargain destined for a project!

linear amplifier for antenna selection, or wired into the tank circuit for band switching.

Give it a try

For both the beginner and the experienced hamfester, these strategies are offered as a starting point from which to develop a personal perspective. Just keep a clear focus on the purpose of your visit. Try not to be involved in circumstances that will tend to distract you. Wear comfortable shoes and a hat if it's a summer event. Even though XYLs (non-hams) and children are generally not charged an entrance fee, don't take them along if you're not certain it will be enjoyable for them. Many men know the equivalent misery they experience as they tag along with their spouses from store to store as the gals surf the mall. If they do not have your level of interest, leave them home. Basically, you must move through the labyrinth of vendor stalls and automobile trunks as quickly as possible. To accomplish this you must do what you have to do in order to remain unencumbered. Doors open early and the activities begin to slacken at about 12 p.m. It's obvious that there's a lot to do in a limited amount of time. Give it a try, and good hunting!

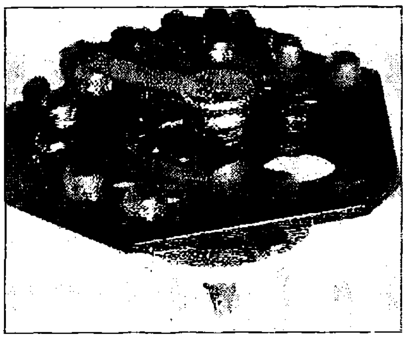

Photo F. Another find—a versatile switch.

LETTERS

Continued from page 63

another evening to install the transceiver in an enclosure. The kit does not include the potentiometers for the main tuning, RIT and the volume control. I would recommend the builder use multi-turn potentiometers for the main tuning and the RIT. Multi-turn pots make the tuning easier and more precise.

I was impressed by the on-the-air performance. The output power with a 12 volt battery is about 2 watts. The receiver is real sensitive and can pick up anything my $700 commercial receiver hears. With my quarter wave vertical antenna, my first three contacts were with stations which were greater than 800 miles from my location. Even though my reception reports were mediocre, we were able to carry on a decent rag chew amongst the fading.

I was also impressed by the quick service provided by Dave Benson NN1G of Small Wonder Labs. The kit was missing one transistor when I received it. After a phone call to Dave, I received the transistor in the mail in two days. I would recommend this kit to anyone interested in QRP operation. I understand that Dave is now offering a 20 meter and 75 meter SSB QRP transceiver for about $100. I don't know how he can afford to sell these kits at such low prices, but I am happy he does.

Listening

Most of us started out as shortwave listeners. I know I did. My grandfather had an all-wave radio and it didn't take long for me to find the 20m ham band and want to know more. Wow, South America, Europe!

Well, you know, most of us have receivers that will tune more than the ham bands, so maybe you'll want to invest in a new book, Radio Monitoring, by Skip Arey WB2GHA. This is a great how-to guide, even for the rank beginner. It explains what's out there to hear and where to find it. 337 pages, $20. Yes, it goes from 10 Hz right on up to the GHz bands. There's a lot of interesting stuff out there when you know what, when, and where to look for it. It covers the various receivers, antennas, and so on. The book is published by Index Publishing of San Diego and should be available in most ham stores... Wayne.

More neat stuff for radio science observing

This month we revisit a couple of topics that are interrelated, but may not appear so initially. By combining the FMG-3 magnetic sensor and the VLF receiver, you will have an interesting method for studying the effects of solar events on radio propagation.

More on magnetic sensors

Not long ago this column discussed the magnetic sensor called the FGM-3 by Speake & Co. Ltd. in Wales, United Kingdom. The FGM-3 and other magnetic sensors are available in the United States from Fat Quarters Software [24774 Shoshonee Drive, Murrieta, CA 92562; 909-698-7950 (voice) and 909-698-7913 (FAX)]. These sensors can be used in a magnetometer circuit to measure the Earth's magnetic field. If you would like to do a bit of scientific investigation, then let me suggest that you build both the magnetometer circuit (contact Fat Quarters) and the VLF receiver we have discussed in this column in the past. Monitoring 10-30 kHz VLF shows a strong increase in distant signal levels when a solar flare occurs. Solar flares lead to Sudden Ionospheric Disturbances (SIDs), which basically wipe out high frequency shortwave propagation.

I'd like to see the correlations between the magnetic event and the onset of the flare as indicated by the magnetometer. Fat Quarters now sells a printed circuit board and parts kit that will allow you to rapidly put a magnetometer into service. The output of the Fat Quarters magnetometer is an analog voltage that is proportional to the applied magnetic field.

More on the VLF receiver

In case you missed the VLF receiver design, I am reproducing the schematic in this month's column. **Fig. 1** shows the circuit diagram for an operational amplifier version of the VLF receiver. This receiver was first designed by Art Stokes for use by members of the American Association of Variable Star Observers—Solar Division. I first saw these designs in Peter Taylor's column in *Communications Quarterly*, and in an article by Stokes. I added the RF output stage, as well as buffering, to the precise rectifier. The RF output stage was added because I found it easier to tune the receiver using an oscilloscope to view the RF signal 2E. A meter connected to the DC output can also be used, but the high value integrating capacitor (C7) makes the tuning peak broad.

The circuit in **Fig. 1** uses a virtual inductor front end. A "virtual" inductor is a circuit that acts like an inductor, but isn't. Operational amplifiers A1A and A1B form a gyrator circuit. The inductance of this circuit is the product of the components shown between A1A and A1B [C3 x 3300 x (R2 + R3)].

Capacitor C2 resonates with the virtual inductance produced by the gyrator circuit to tune the desired frequency. For the values of C2, C3, R2 and R3 shown, the circuit will tune from about 15 kHz to more than 30 kHz. Resistor R3 is the tuning control. It is a potentiometer, and should be either a multi-turn model or connected to the tuning knob via a vernier reduction drive. I elected to use a ten-turn trimmer potentiometer because it is rare to retune the unit after homing in on the station that you want to monitor.

The receiver front-end amplifier consists of amplifier A1C, which has a maximum gain of x101 [i.e., (R7/R6) + 1]. The output of A1C is an RF signal with a frequency equal to that tuned by the gyrator and C2. This signal is coupled to the RF output stage (A2A) through capacitor C5. The RF output stage shown here is a noninverting operational amplifier circuit with a gain of x2. I found that this gain was a little too much for power stations, so eventually I eliminated R14 and R15, and connected the output of A2A (pin 7) to the inverting input (pin 6). This changes the circuit from a gain-of-2 noninverting follower to a unity gain noninverting follower. Some people might want to keep the amplifier if they are in a weaker signal area.

The DC output circuit consists of a precise rectifier (A2B). The precise rectifier works like a regular rectifier, but does not have the low-voltage "knee" between 0 and 0.6 volts (for silicon) or 0 to 0.2 volts (germanium). The pulsating DC from the precise rectifier is filtered and smoothed to straight DC, at a value proportional to the signal strength, by an R-C integrator consisting of R12 and C7.

The buffer amplifier (A1D) is used to isolate the precise rectifier from the RF output amplifier. Before incorporating the RF amplifier I found that the action of the precise rectifier distorted the RF output waveform.

The VLF receiver can be built using ordinary operational amplifiers, provided they have the gain at the desired frequencies. The pinouts shown in **Fig. 1** assume a type 4136 for A1, and a CA-3240 for A2. Both are available from Digi-Key and in Jim-Packs at electronic supply stores. If you want to use all CA-3240, or single CA-3140 devices, simply adjust the pinouts accordingly. The CA-3240 is a twin CA-3140, much like a 1458 is like a twin 741.

Your setup

The next step is to obtain a means for recording the voltages from the FGM-3 and VLF

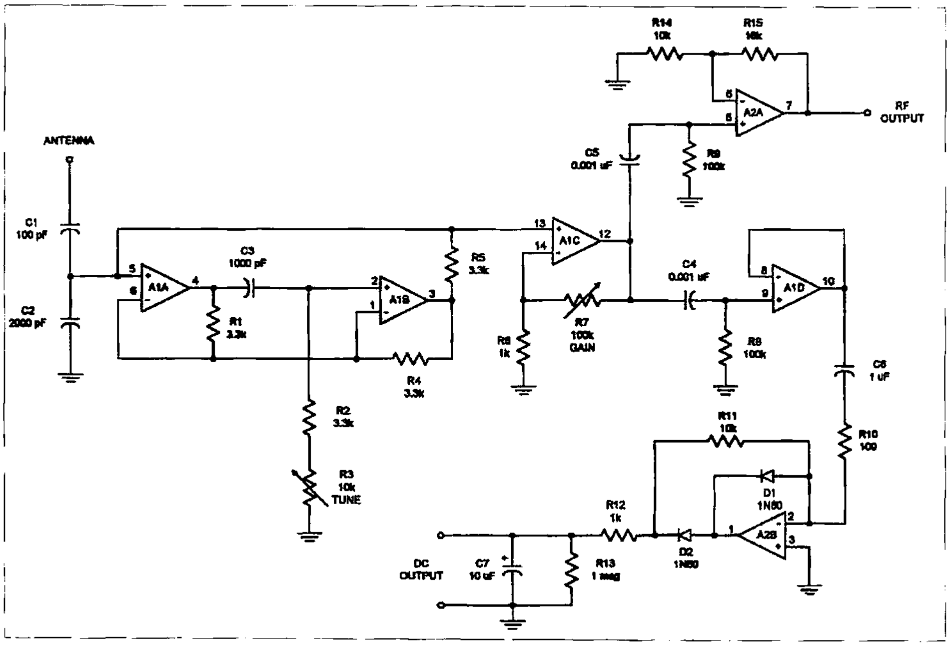

Fig. 1 The circuit diagram for an operational amplifier version of the VLF receiver.

receiver. If you are lucky enough to own (or can get) either a strip-chart recorder or X-Y recorder, especially a two-channel instrument, then your problems are solved. *If* you can get pen and ink supplies for it. Otherwise, might I suggest looking in the various magazines for an A/D converter? What you want is an A/D converter with at least two channels, that will convert the 0-5-volt DC range, at a rate of at least one conversion per second.

The A/D converter that I use works through the serial port of a personal computer. The software is DOS-compatible, so it will work with either DOS only or Windows 3.x machines. The device is made by Pico Technology Ltd. (Broadway House, 149-151 St. Neots Road, Hardwick, Cambridge, CB3 7QJ, England). They can be E-mailed at post@pico tech.co.uk, or via the World Wide Web at http://www.picotech .co.uk/. Pico Tech accepts Visa, Master Card and American Express, so you can order from the USA. I have had no problems ordering from UK firms via credit card, so don't anticipate any in the future. Also, I have never been charged import duty... all came "passed free" by the US Customs Service. I cannot guarantee that yours will come that way, but it's likely.

New books

I recently published three new books under the Newnes imprint. *Linear IC Applications* and *Linear Integrated Circuits* are published by Newnes/Butterworth-Heinemann in England, but should be available from their US office. *Microwave & Wireless Communications Technology* is published by Newnes/Butterworth-Heinemann in the US. All three books can be ordered in the US by calling 1-800-366-2665. If you want additional information, the op-amp books can be viewed at World Wide Web site: http://butter worth.heinemann.co.uk. Click on "technical books" and follow that or the new titles pathway to find my two mini home pages.

For viewing the microwave book, try site http://www.bh.com. This is the US site. In both cases, you can order through the Internet by either filling out the form and mailing it in via snail mail, or supplying your credit card information via E-mail. Because of security problems, however, I strongly recommend against ordering by sending your credit card data via the Internet. I would rather lose the sale than have you in trouble because of a credit card cyber-thief.

Connections

I can be reached via snail mail at P.O. Box 1099, Falls Church VA 22041, or via Internet E-mail at: carrjj@aol.com

Whether via ham radio or the Internet, one subject with which we're all becoming more familiar is video. From JPG and GIF to ATV and SSTV, picture transmission is coming into its own—so I thought it would be fun to take a break from our usual repair topics and examine video: its history, its signals and its peculiarities. Let's have at it:

The big difference

Video signals are vastly unlike audio signals. Why? It all comes down to one essential difference between sound and light: Light travels in straight lines and sound does not. Thus, light can form spatial patterns far more detailed than can sound.

This doesn't mean, of course, that dimension is not an issue with sound. We are born with two ears for a reason: Localization of sound arises from differences in amplitude and phase as the sound arrives from various locations to our ears. With only one ear, it is nearly impossible to know from what direction a sound is arriving. There are some secondary effects due to the curvature and asymmetry of the outer ear, and they can give some clues, especially regarding front and rear. But, without binaural reception, you can't get much localization. After all, can you tell whether somebody's sitting to the left or right of his radio's microphone when he's talking to you on it? Nope.

Although you certainly can hear two sounds at once, or even many of them, in reality, they're a combination of the waveforms of each sound into one composite waveform which has a definite value at any given moment. The separation of this waveform into its constituent parts is due to a miraculous feat of the human brain, which is way more powerful than any DSP chips we've yet created. So, even though you can hear an entire orchestra playing together, it's reasonable and fairly correct to think of sound as a serial, or one-at-a-time, medium, and it can easily be transmitted as such.

Because of light's traveling in straight lines, it has the capacity to form detailed spatial images. The implications of that are tremendous. Suddenly, you can't describe the whole of the information in serial fashion, because, in addition to having colors and intensities (roughly analogous to sound's pitches and loudnesses), you've also got variations of these things happening *next* to each other! In other words, you have serial events happening in parallel. That added dimension complicates matters quite a bit.

Way back when

Believe it or not, people were experimenting with television before the turn of the century. (Hmm, I guess in another couple of years, that phrase will mean something entirely different.) Even in such a technologically

primitive time, it was recognized that there was no practical way to transmit parallel events, whether over wire or, later on, via radio. There had to be some way to serialize a picture for transmission. There was, and it's essentially the same one we use today.

The concept of scanning an image and sending it serially, dot by dot, goes back to the earliest experiments with picture transmission in the late 1800s. Breaking an image up into dots had some limitations, notably in how many dots you could send per second, but it seemed the only choice. In pre–vacuum-tube days, the only way to do it was mechanically, so TV pioneers did just that!

One early experimenter by the name of Nipkow proposed a workable TV system using a rotating disk with holes in it, in 1883. By arranging the holes in a spiral pattern, he was able to scan an image, line by line, much as we do today with electron beams. It took a big disk to make a small picture, though, so his pictures were limited to under 40 lines of scanning, whereas ours can be in the hundreds or even thousands. Did it work? You bet it did! Of course, at that time, it was limited to being a laboratory curiosity, with pictures sent over wires to a nearby receiver, since radio wouldn't get off the ground until Marconi "invented" it in 1895. Imagine: People were playing with TV before radio! Even more amazing, a Scotsman by the name of Campbell-Swinton proposed the fundamentals of modern, electronic television in 1908, long before the equipment to produce it would exist. (Actually, the cathode-ray tube was invented in the late 1800s, but it took great imagination to envision using it for the display of pictures, and the concept of storing an optical image on a charged plate in the camera was wild and unique. Yet, that's exactly how it would eventually be done, nearly 25 years later.)

As early as the 1920s and 1930s, Baird in England and Jenkins in the USA had created working Nipkow-disk–based TV sets, and some radio stations were broadcasting TV programs, with the viewers connecting homemade disks with neon bulbs (which, unlike incandescents, can turn on and off fast enough to form the picture dots) to their radios' speaker leads, via step-up transformers. The bulbs would flash on and off with the received signals, and the spinning disks would form those flashes into images by scanning the same line pattern as the transmitter's disk. Synchronization of the disks was accomplished by the viewer's speeding up and slowing down the receiving disk until the image looked right. The resulting pictures were crude, but they were *pictures!* Baird sold finished sets, had his system adopted by the BBC, and even demonstrated a disk-based color TV system. Further, he invented and actually sold the first videodiscs, which stored programs on phonograph records, all in the 1920s! These brazen beginnings set the stage for the television revolution, and we've never looked back.

"Can you tell whether somebody's sitting to the right or the left of his radio's microphone when he's talking to you on it?"

Seeing pictures transmitted from far away was a tremendous thrill, but there were serious inherent limitations in the mechanical system. In addition to its huge cabinet-to-picture size ratio, mechanical TV had very limited resolution (number of dots per picture), poor gray scale (it was hard to get the brightness of neon bulbs to track that of the received signals), and there was no persistence of the dots between scans, resulting in a very dim, flickery picture. Clearly, the scanning concept was right, but the moving parts had to be done away with. Zworykin and Farnsworth were working on all-electronic television in the 1920s, and finally succeeded in making practical, all-electronic TV ready for the masses by replacing the scanning disk with a moving electron beam in a tube. It wasn't until after World War II that TV really got off the ground, though. The 1950s became the "golden age of television."

Faster is better

What made the electronic system so superior to the old mechanical one? There were several factors, including phosphor persistence that made for bright, flicker-free pictures, good gray scale, a much better cabinet-to-image size ratio, automatic synchronization, and no whirring mechanical disks. Far and away, though, the biggest improvement was in the amount of information each picture could contain. Without the need for a giant disk, the number of lines scanned went from about 40 to 525, with 30 complete frames every second! And, each line could contain many dots of information, making for a vastly more detailed image. With the small screen sizes then available, it looked nearly as good as a film shown in a movie house, and you could see it all for free in your living room. It was irresistible.

Providing so much detail on the screen each second required a lot more information to be transmitted in the first place. TV could no longer be broadcast in the 5 kHz bandwidth of an AM radio station. The new electronic system needed 6 MHz of bandwidth for each station, which is about 12 times the size of the *entire* AM band! So, TV stations had to move to VHF and UHF frequencies, with today's channel 2 starting at 54 MHz. (There was once a channel 1, but it was lost to changes in the frequency allocations.)

Lock on

Automatic synchronization was a must for electronic television. With the scanning disk, you could play around with its rotational speed and position until you got a synced picture. And, if you were lucky, it might not drift out of sync for a few minutes. With electronic circuits, that was impossible; without the mass of the disk, the drift rate was intolerable. So, while the mechanical TV's signal consisted entirely of picture information, the modern signal was devised to contain sync pulses that told the set where and when to start the scan, both for the beginning of each frame and for each line within it. They were called, appropriately, vertical and horizontal sync. Even with all this, though, there was still one problem.

I said before that electronic TV gave flicker-free pictures. That wasn't entirely true at first. The decay rate of the phosphors in the picture tube (how long it took for them to lose brightness after being struck by the electron beam) wasn't really long enough to keep the top of the picture bright by the time the beam had gotten to the bottom. Early experiments found that the resulting flicker was troublesome, so a clever, essentially free solution was found: First the set would scan all the odd-numbered lines, and then go back to the top and scan all the even-numbered lines in between them. The amount and rate of information transmission and display was the same, but the beam got to the bottom of the screen twice as fast and twice as often, tremendously reducing the amount of flicker. This breaking up of the 30 frames into 60 fields was called "interlaced scanning," and has remained an important feature of TV systems all over the world, to this day.

Well, I think we've done enough TV history for one month. Next time, we'll look more closely at the television signal, color and recording. Until then, 73 de KB1UM.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

As I write this, there are developments on the digital front I find rather troubling that shall form the nucleus of this month's column. While they may not concern everyone, their implications may well be far-reaching.

Little Orphan AEA

Back in July, 1996, I received a piece of E-mail from the folks at AEA, makers of the popular PK-232 multimode terminal unit and other digital devices, eager to link with the RTTY Loop Home Page on the World Wide Web. As many of you who have visited the page know, I maintain a variety of links to various sites related to amateur radio in general, and digital communication in particular, on the Web site. Anyway, we established such a link.

Then, in November, I heard from John P. Skubick K8JS, who wrote: "I browsed your Web pages again after a long hiatus. Nice! I read RTTY Loop each month and enjoy it.

"Actually, for your pages I prefer my usual browser, Netscape Gold 2.02©; it's better than IE 3.0© and is also very stable. IE 3.0 and previous versions of it have always been new and unwelcome 'adventures' the few times I have booted them up.

"I've been digitally inactive from ham radio for about 1-1/2 years. Before then, I was almost exclusively digital with PACTOR, AMTOR, and some packet—lots of fun, especially the long PACTOR/AMTOR ragchews with the VKs & ZLs on 20m.

"My trusty and reliable and 'stable operating' Amiga got zapped from one too many hits from the local power company's outages. Six months later I got a new 'P100' and installed OS2 Warp. (After that terrific Amiga system, I just could not put up with the archaic Win3.xx.) Warp 3.0 was not without its 'unique' logistical problems (software & drivers), so I switched over to Win95© and its subsequent enhancements & updates. Over all, W95 is very nice for me. Olde Windows? Yuk!!

"I have been active all of this time using 'basic digital' (CW) and some SSB. I have largely procrastinated [in using] the digital modes because I had drastically re-done the operating position with roll-top cabinets and hesitated to re-do 'all of those TNC cables' from the PK-232 to the HF and 2-meter rigs. Yes—a poor excuse.

"Now, I got interested in digital hamming again and was planning to get a shiny new PK-232. And, guess what? AEA, just went out of business a few days ago! Can you believe that? It's true, all right. I wonder what the heck happened to them? They had the best TNCs as far as I'm concerned. I may get that German-made PTC-II TNC; I just don't know yet. PACTOR II seems promising, but I have reservations about G-Tor's future."

Well, I enjoyed the comments about the column and Web site, of course, but was a bit taken aback by the news of AEA's demise, so I asked John where he had heard the news.

He replied: "About a week or so ago I read this about AEA on the Web-based *Ham Radio Online* magazine. A few days later, AEA's Web pages disappeared. I noticed that *QST* and a few other mags did not have any AEA ads in their respective November issues. The December *QST* just arrived, and not only are the usual AEA ads missing, but not a word anywhere in it about their demise. It's the same with the December *73 Magazine* that just arrived. No info. Nothing."

Oh, well, I guess I didn't need that new DSP-232 after all.

With this information, I checked the blurb on *Ham Radio Online*, an online magazine which can be found at: http://www.hamradio-online.com, which reported that as of November 15, 1996, AEA closed its doors and went out of business. While there are suggestions that they have been looking for a buyer, I have been unable to turn up any new information about the company from my perspective.

So there you have it. A manufacturer whose product was positioned at the top of the amateur radio market bites the dust. Of course, this is nothing new. Those of us in the hobby for many years recall legions of amateur radio names that no longer claim shelf space. From Hallicrafters to Heathkit, or Hammarlund to Gonsel, many a company has either bailed out of ham radio or folded altogether.

"There have been some rather troubling developments..."

So if AEA joins them, farewell—it's been nice. Or if a company like G & G steps forward, as it did to rescue Microlog customers, there may be some life in the 232s yet. Only time will tell, and I will keep my eyes and ears open for news. Watch here, and on the Web site, for further information.

In the meantime, we are all going to have to help out those who are new to these modes. To wit, a letter from Clarence Hermance W6RRN, of Stockton CA. He writes:

"I have been a fan of your column since I had my first model 19, so long ago. I have made some of the modems I have used over the years from your column. Now as time has passed, I have been buying the equipment instead of building from 'scratch.' My first purchase (years ago) was a CP1 for my Commodore. Worked great until I got the 'IBM clone.' Then your column showed how to put a RS-232 port on it—which I built. Haven't got it to work as yet with Hamcomm 3.1©, but I will figure it out. I think something was left out of the directions for making the jumpers on the CP1.

"Now for my latest problem. I purchased an AEA PK-232MBX with the PACTOR chips installed. It was the only one I could find in November, 1996. It was sold to me as a clearance item, as the salesperson said it was discontinued. They never told me the company had closed up. After getting it home, I found that it had apparently been a used unit or a demonstrator which would not work PACTOR. The program said it 'does not support PACTOR,' yet I was using Packratt II version 5.5a. Apparently the chips are bad, but with the company closed up, I have no way to get new chips or have the unit repaired if that is what is wrong.

"Do you have any information on where we (I and others) can get our AEA equipment worked on? This sure poses a problem to me and a few others who will need to get our equipment serviced in the future."

As I have no good information on the PK-232MBX, I turn it over to you all. My only hope is that, if nothing else, a users' group will arise to help Clarence, and others who have problems with their AEA units.

I look forward to hearing from any of you by snail mail at the above address, or via E-mail at ajr@ari.net, MarcWA3AJR on AOL, or 75036,2501 on CompuServe. Check the RTTY Loop Home Page at http://www2.ari.net/ajr/rtty/ for further developments as well.

March may turn out to be a very exciting month for HF-band propagation and also for ionospheric, atmospheric and geophysical activity. It looks as if the first two weeks of the month may be rather bland and quiet, with only seasonal improvement in DX potential. The last two weeks, however, could be wild. There is a good chance of the ionosphere exhibiting active-to-minor storm levels on or around the 17th to 19th, the 26th, and again around the 29th and 30th. These periods may also bring some atmospheric storms and other geophysical events to various locations.

Seasonal increases in daylight hours in the northern hemisphere bring more UV stimulation of the ionosphere—hence greater DX potential. Also, an expected increase in solar flux due to the anticipated increase in sunspots as Cycle 23 begins its five-year rise, should help DX chasers. It is sometimes noted that the occurrence of ionospheric storms, accompanied by high signal absorption, is followed soon after by exceptional DX propagation opportunities...so don't be discouraged by poor conditions.

As you scan the band-time-country chart, be aware that when 15 meters is indicated, check 12 meters, too; when 20 meters is indicated, check 17 meters. If 40 meters is shown, be sure to try 30 meters, too. Propagation is where you find it, and forecasting is often as much an art as a science. Surprises can and do occur, so it pays to be alert and do some searching above and below the noted frequencies, and also before and after the noted times.

10 meters

DX possibilities are poor, but occasional openings across the equator may be possible to tropical areas.

12–15 meters

Circuits to Africa and South America can occur on Good days as shown on the chart, and short skip out to 1000 miles or more will be frequent on Good days.

17–20 meters

Twenty should be the best band for DX, with 17 coming a close second. The band should be open until after dark, with long openings into the southern hemisphere. Short skip from a few hundred to about 2,000 miles will be frequent during daytime.

30–40 meters

These bands should remain open for DX from sunset to sunrise. Signals from the east will peak between dark and midnight, while signals from other directions will peak between midnight and dawn. Daytime short skip from 100 to 1000 miles and nighttime short skip from 1000 to 2000 miles can be expected.

80–160 meters

Increases in QRN may limit DX opportunities to "quiet" evenings, and short skip between 500 and 2000 miles will be common on 80 meters. On 160, short skip and DX during hours of darkness, peaking around midnight and again at dawn, should be a regular occurrence... limited only by QRN. There will be *no* daylight activity, due to absorption. 73

RFE/RL Assists Banned Serbian Reporters

On December 4, 1996, Radio Free Europe/Radio Liberty began expanded news and current affairs programming, In cooperation with Radio B92, the last independent broadcaster in Belgrade, which Serbian authorities silenced on Tuesday, December 3.

RFE/RL's Belgrade news bureau is working with journalists from B92 to provide impartial and uncensored news, interviews, analysis and discussion of the current political situation in Serbia.

A 30-minute program is broadcast daily from 21:00 to 21:30 Belgrade time on 1593 kHz from a 150,000 watt AM transmitter at Holzkirchen, Germany. An additional 30-minute daily program is broadcast 19:00 to 19:30 Belgrade time, on 792 kHz from a 500,000 watt AM transmitter at Kavala, Greece. Both stations are operated by the U.S. Information Agency's International Broadcasting Bureau.

On the air since January, 1994, RFE/RL's multiethnic South Slavic Language Service—staffed with prominent Serbian, Bosnian and Croatian journalists—currently broadcasts two and a half hours daily to the former Yugoslavia. Director of the service is Nenad Pejic, former program director of independent Sarajevo TV.

The service has become a leading source of unbiased news and current affairs from throughout the former Yugoslavia, the neighboring region and the world at large. From two and a half hours daily, broadcasting has now expanded to three hours.

Based at RFE/RL's broadcast center in Prague, the service draws on more than 30 correspondents working through bureaus in Belgrade, Sarajevo and Zagreb, and from Washington, Brussels, London, Moscow and other major capitals.

Since 1994, radio B92 has broadcast one hour of RFE/RL's program daily. The service's programs continue to be broadcast on seven other independent local FM stations in Serbia and Bosnia. RFE/RL also produces a half-hour weekly television program that airs on independent stations In Bosnia.

RFE/RL is a private, non-profit public service broadcaster funded by the U.S. Congress. Relocated from Munich, Germany, to Prague in 1995, its 21-language services broadcast 700 hours weekly to eastern Europe and the former Soviet Union.

From *RFE/RL News.*

Computerspeak

Keypad: An apartment with a lock.
Keyword: "Your place or mine?"
Light Pen: A minimum sentence prison.
Line Feed: "I've never met anyone as interesting as you before," etc.
Machine Independent: The goal of all computer haters.
Machine Language: "Zoom, Putt-Putt, Chug-a Chug-a," etc.
Memory: The part of a computer where data is placed prior to destruction.
Multipass: To try again after she turns you down the first time.
Menu: An Itemized list of ways to make a mistake on a computer.
Microminiaturization: "Get small" in computerist's language.
Mnemonic: Said of someone suffering from mnemonia.
Monitor: The first iron-clad CRT.
Multi-processing: To cook statistics more than once.
Multi-programming: To watch all three networks at once.
Multi-tasking: When one "tsk" won't do, e.g., "Tsk-tsk-tsk."
(Note: Under the most rigorously controlled conditions of pressure, temperature, humidity and other controllable variables, a computer will do what it damn well wants to do.)
n: After x, the second most popular number that doesn't mean anything.
Nanosecond: A witness to a duel between grandfathers.
Night Mode: computing in pajamas.
Network: What fishermen do when not fishing.
Non-Impact Printer: One whose signs go unnoticed.
Nybble: What an unsuspecting customer does to a line dangled by a computer salesman.
Overstrike: To tempt fate, e.g., air traffic controllers.
Office Information System: The word processor who knows the most gossip.
Ohm: Where the 'eart is.

Note: These definitions are not Intended to offend anyone. They are taken from *The Computer Hater's Handbook* (1983), as printed, and it is hoped they will be taken lightly and with humor, as intended.

Ham to ham

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

This month's "Ham To Ham" has an interesting potpourri of ideas, so let's get right to it.

Stud power

From Mark Marholin KE6JJR: "If you're faced with having to replace a stud-mounted RF transistor in your commercially-made rig, or perhaps you're building an add-on 'brick' amplifier for your VHF or UHF low-power transceiver, here are some points to keep in mind before starting the job. I've hard-won these ideas over my own years of building RF amps in the 50 to 450 MHz range.

"Before mounting the ceramic-bodied, stud-mounted 'final' transistor(s), try to form the flat copper leads (bands) on the transistor as closely as you possibly can to fit the board foils and the opening in the circuit board which the transistor body occupies. This may require first bending the flat leads up at an angle, then down somewhat again for the right fit. It's much easier to do all of this pre-fitting ahead of time. Once the leads are preformed, trim off the excess to avoid unexpected additional inductances ... especially in UHF circuitry.

"Now, pre-tin the undersides of the flat leads so that when the transistor is finally in place, solder will flow smoothly and easily underneath the flat leads without the need to apply excessive amounts of heat (which might be bad for both the board and the transistor itself).

"A good quality thermal-conducting grease (silicone grease) should be applied to new transistors and any mica washers or insulators that might be involved, but don't overdo it—too much thermal grease can actually hamper heat transfer, or worse yet, can deform the flanges on some devices when they're finally torqued down.

"And speaking of that final torquing down of the nut on the transistor's mounting stud, try not to apply counterpressure by holding the device by its leads; they're not meant to stand that degree of strain. Even after soldering the leads in place, don't depend on them to prevent the transistor from twisting during the stud-tightening procedure. Stud-mounted devices usually have a flattened end on their threaded studs; hold the stud in place by that flat—that's why it's included. I hope that some of these tips prove to be worthwhile for your next power transistor installation."

Reducing heat buildup in tube amplifiers

From Richard Measures AG6K: "Excessive heat buildup, within any piece of ham radio gear, can greatly affect the trouble-free equipment life expectancy period of that equipment. In case you're in doubt, it's generally accepted that electrolytic capacitors can be expected to decrease in life expectancy by one-half for each 10 degree Celsius rise (18 degrees Fahrenheit) above normal room temperatures. This alone should be enough to convince most of us of the importance of keeping the tube compartments in older HF transceivers, and in amateur linear amplifiers, as free from heat buildup as possible.

"Another reason is the often self-destructive effects that too much heat can have on higher-power amplifier tubes—such as the popular 3-500Zs—used in many ham linears. These tubes will normally run with an orange glow on the anode material, with the expectation from the tube's designer that much of the internal heat will be dissipated by radiation and absorbed by the cooler surrounding metal chassis structure. Just as often, however, those surrounding metal parts are shiny reflective aluminum or steel, and send a large amount of that radiant energy right back into the tube instead of dissipating it as the designer intended.

"By painting the insides of these tube compartments a flat black, considerably more of the radiant energy will be absorbed and safely carried away than if the metallic surfaces are reflective and force the energy to bounce back and forth between the tube(s) and the enclosure. This is a simple point of physics that some product design engineers overlook: Bright or shiny surfaces always reflect, and dark dull surfaces always absorb radiant energy, and heat is radiant energy. Kenwood's TL-922 linear amplifier, as an example, *does* have flat black tube compartment walls.

"If your particular amplifier doesn't, black liquid shoe polish is one simple answer. Apply it evenly to all of the reflective compartment surfaces, especially those that would reflect radiant energy right back into the tubes themselves. This simple step will help the equipment's cooling fan to do its job, and help to keep your gear functioning longer, cooler and more trouble-free."

Moderator's note: I've applied Rich's idea to my own Heath SB-1000 and can vouch for its effectiveness. I painted the internal walls of the tube compartment with flat black paint and immediately noticed a substantial increase in the amount of heat absorbed by the compartment walls; very little of that heat will find its way back into the 3-500Z itself. What modification could be simpler? Just make sure that the power is unplugged and the power supply's capacitors are completely discharged when you're working inside any compartment that carries high voltage. I always clip a jumper from the anode of the tube to ground whenever my hands are in or near the final RF compartment. I learned the value of that years ago when working inside broadcast transmitters. "Inside" is the right word; you could actually walk inside our VHF TV transmitter!

Workbench pin-up

From John Nix: "Fig. 1 shows a handy nomogram to keep near your workbench. The dictionary definition of a nomogram is 'a graph that enables one, with the aid of a straightedge, to read off the value of a dependent value when the values of two or more

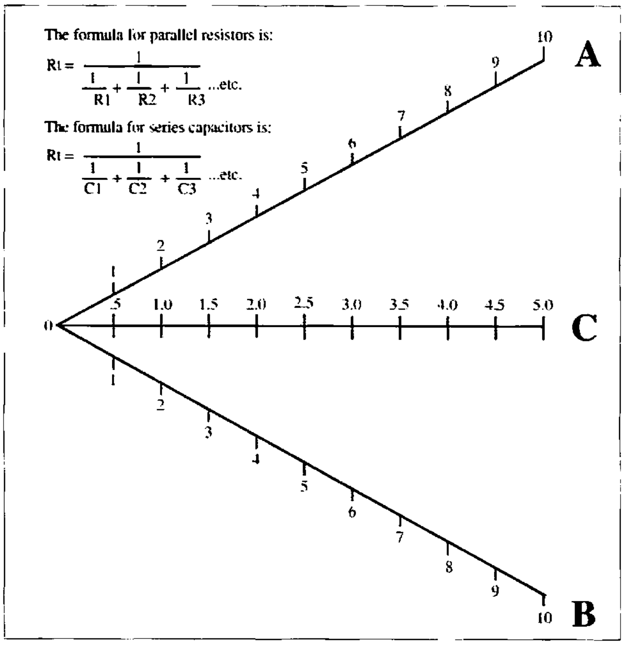

Fig. 1. John Nix's nomogram for approximating the value of parallel connected resistors or series connected capacitors. Lay a straightedge across the graph from Scale A to Scale B at the point representing the two component values, and the resulting equivalent circuit value of those two components is read from Scale C.

independent variables are given.' This one allows you to quickly approximate the equivalent value of two or more parallel resistors or two or more series capacitors. Simply lay a straightedge between the values that you want to combine on the top and bottom angled lines (Scales A and B), then read the equivalent combined value on the straight line in the middle (Scale C). It's much faster and easier than struggling with the all of the division needed for the 'standard' parallel resistor or series capacitor equivalency formulas (also shown in **Fig. 1**).

"For instance, a 270 ohm resistor in parallel with an 820 ohm resistor is 203 ohms. A .022 µF capacitor in series with a .047 µF capacitor is .015 µF. Remember that the value will always be lower than the lowest of the two individual component values for resistors in parallel and capacitors in series.

"To figure multiple resistors in parallel or capacitors in series, simply use the first two values and find the equivalent on the nomograph, then use that answer plus the third value for the next equivalent and so on until all of the values have been accounted for. The final value is the overall equivalent circuit value of all of the components in that parallel (resistor) or series (capacitor) circuit."

Moderator's note: The nomograph in ***Fig. 1*** *is only useful for values within the same power of 10, i.e., when all of the resistors in a parallel circuit are in ohms, hundreds of ohms, thousands of ohms (k), etc. To find the equivalent of a 470 ohm resistor in parallel with a 10k ohm resistor, best use the longer formula (by the way, the answer is 448.9 ohms!). Thanks for another nice chart, John.*

Big dipper

From Phil Salas AD5X: "For waterproofing outdoor connections and connectors, I've had very good luck with a product called Plasti-Dip™. It's a fast-curing liquid plastic material that's intended primarily for coating tool handles. A can of it costs about $7 at hardware and home centers, but it should last you a good long while. I usually put two coats of it on all of my outdoor connections. For wire connections, such as separating a coax shield and center conductor for feeding a dipole antenna, I immobilize the point where the shield and center conductor separate with hot glue (hot glue guns are great for a lot of things like this). Then I attach solder lugs to the ends of the shield and center conductor as the connection point to the antenna's balun. Finally, I dip the entire end of the coax (including the solder lugs) into the Plasti-Dip and let it cure. After curing, I use a hobby knife to trim off the excess Plasti-Dip insulation that covers the ends of the solder lugs. Neat, easy and if done correctly, waterproof!"

TTT (transformer test tip)

De your moderator, Dave NZ9E: Here's a tip for easily and accurately testing the insertion loss of transformers, whether they are AF transformers or RF transformers. Testing the actual dB loss in step-up or step-down transformers is tricky because of the different impedances presented by the primary and secondary windings: dB loss formulas assume like impedances on the input and output of any device where dB gain or loss is to be calculated. But with transformers, this criteria is easy to meet, simply by using two identical transformers (same type number) and hooking them up back-to-back (see **Fig. 2**). Now the input and output impedances are identical, so the loss can be measured by simply comparing the differential in voltage between the input of the two and their cascaded output, then dividing that result by two. If your measurements indicate a 6 dB loss using two identical transformers back-to-back, it's safe to assume that each is responsible for 3 dB of that loss, certainly close enough for all but the most exacting applications.

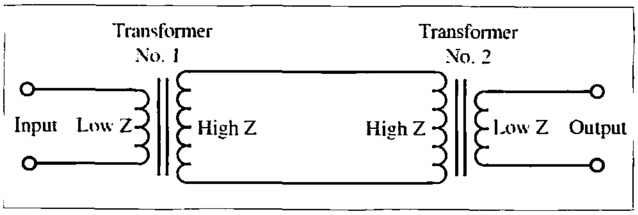

Fig. 2. *Two identical transformers connected back-to-back for easily checking their insertion loss in dB. See NZ9E's tip in the text for further details.*

"You've just uncovered your 'hidden' QRP meter and you didn't even have to lift your soldering iron to do it."

Hidden QRP wattmeter

From Ken Guge K9KPM: "Wanting to accurately measure the 2 watt RF output from my Kenwood HT, I spotted the Daiwa CN-550 cross-needle VHF SWR/Power meter sitting on my operating bench. The Daiwa CN-550 measures forward and reflected power directly in watts, with two separate meter needles, and then it 'computes' (on the meter's scale) the SWR by where those two separate needles cross. I'm sure everyone's seen this type of meter even if you don't currently own one. The forward power scale has a range of zero to 20 watts on its most sensitive range, but even at that, the 2 watt point for my HT's RF output is only about the lower one-fifth of the full 20-watt scale markings—OK, but not great for accurate QRP measurements.

"It occurred to me that the reflected scale, zero to 4 watts, would be the perfect one to use, with the zero to 2 watt portion on the scale covering about three-quarters of the meter's range; several magnitudes better than the forward scale. It's amazingly simple to use that reflected scale for measuring low power outputs—simply hook the unit up backwards!

"Instead of having the HT's output cable going to the 'TX' connector on the CN-550, connect it to the 'ANT' connector instead. Then put your dummy load (a low power one is fine) on the 'TX' connector of the meter. You won't be able to see your SWR correctly, but you no doubt already know that your dummy load is very close to 1:1, so it's no loss. What you will see, though, is your forward power—now on the 'reflected' scale—in far greater detail. Small adjustments can be made to your low power HT and the results will be easily visible on the zero to 4 watt right-hand reflected scale. You've just uncovered your 'hidden' QRP meter and you didn't even have to lift your s oldering iron to do it."

Moderator's note: I've had a Daiwa meter like the one that Ken mentions above for years, and have never really seen it in that light before! Ken's idea clearly illustrates what 'ham ingenuity' means: Looking at an item from another point of view and 'inventing' a new use for it. Of course you can apply the idea to any of Daiwa's (or other manufacturers') dual-needle meters, in any frequency range. Another nice tip, Ken.

That wraps up this month's column; does anyone have any ideas on "different" uses for common items such as K9PKM gave us? Send them, or any other ham-related tips, ideas, suggestions or shortcuts to me at the address in the masthead, and I'll share them with the rest of *73*'s readers. That's our purpose, sharing practical ideas Ham To Ham.

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Well, it looks like we made it through another winter in the Midwest. Lucky for me, this year I don't have to fix the damage old man winter did to my antennas. On the other hand, I spent most of the winter with nary an antenna. What little hamming I've been able to do has been with a mobile HF antenna affixed to the car—with a run of coax into the apartment. Needless to say, I can't wait for the house to be finished. But while I wait, I can plan my dream antenna farm. During the best of times, I've never really had a "really good" antenna system. With three acres on the new home site, I can grow lots of antennas.

Even if you don't plan to redo your entire antenna farm, if you're running low power you need to get every last milliwatt in the air. Winter can be really tough on your antenna farm. So, before the grass starts to grow, let's look at what is left, and the best place to start is the feedline.

You get what you pay for

And when it comes to feedline, if you try and save a few nickels here, the results will surely bite you in the butt! Lossy cable may work if you're running 100 watts. Even if you are using really bad coax and lose half your power to the cable, you only lose one S-unit. At the levels most QRP operators use, losing half your power to lossy feedline (and that same S-unit) would be a death blow to your signal.

So, if you purchased your feedline new with the rig, and that rig has tubes in it, replace the coax! Unlike fine wine, coax does not get better with age.

So when should you replace your coax? I really can't say. Coax used up and down the tower should be checked/replaced every five years or so. If you live in a climate having lots of sun or salt mist, perhaps you should change it more often.

"Unlike fine wine, coax does not get better with age."

The outside jacket should be free of cracks and abrasions. If you find your feedline looks fine except in one or two sections, don't try to splice in new runs. Aside from the extra work, it's not really going to fix the problem. Water may have seeped into the line and ruined it. Damage from rabid ice weasels may go unnoticed as well. Run your hand along a section of coax. If your hands turn the color of the coax, UV damage has occurred; replace it.

Check the connectors at both ends (see **Fig. 1**). The jacket should be inside the barrel of the connector. Any exposed braid means there's a good chance water may have entered the coax. Of course, if you can see the connectors, why didn't you seal them off with some tape and coax sealer after you installed the coax in the first place?

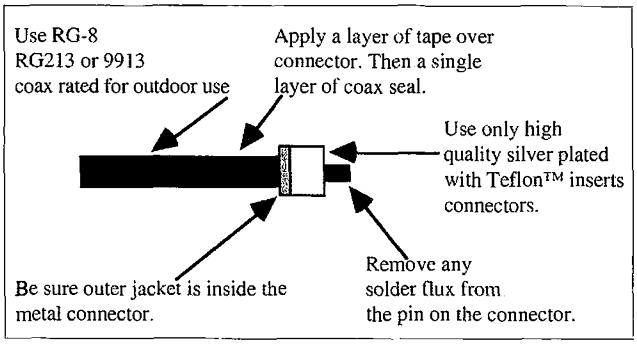

Fig. 1. Proper protection of outdoor coax connectors.

What coax to buy?

Always buy a name brand. I don't care what the guy behind the counter says; if the stuff is any good, the manufacturer will put his name on it. You really do get what you pay for. Don't go for the surplus coax either, unless you know where it came from. Fresh surplus is fine, but stuff from World War II is just wasting your money.

For runs up the tower, I always recommend and use RG-8 cable. Another really good cable to use is the RG-213. It's about the same price as the RG-8, but with slightly lower loss specifications, especially on the upper frequencies. 9913 is also a good choice for HF. Check out the *ARRL Handbook* for a listing of different coaxes and their losses at various frequencies.

Just like chocolate, there are zillions of varieties of RG-8. You'll see UV resistant, direct burial and abrasion resistant, among others. Get the kind you need, but don't pay more for something you don't need.

Connectors

While shopping for new coax, how about the connectors on the ends? Please don't waste your money and get those cheap imported guys with the plastic centers. They're just not worth the hassle. I always choose amphenol RF connectors. And I always go with the silver-plated connectors, too. The last ones I used had the Teflon™ center. I highly recommend you do the same. If you're not an expert at attaching an SO-239 connector, the Teflon will allow you some leeway when soldering. The plastic center connectors will melt! Get the connector hotter yet, and the center of the coax will melt as well!

Is the gold SO-239 any better? Well, *I'm* not going to spend the extra money to find out. The gold would prevent the connector from becoming corroded, but other than that, I'm not sure they are worth the money.

There's been a lot of paper consumed showing hams how to put on an SO-239 connector. I suggest you take a look in the *ARRL Handbook* for a step-by-step walk-through. I can tell you those small holes around the barrel of the connector are not to let the steam out.

To install a connector onto an end of coax, you'll need the following: First, use a clean connector free of dirt and corrosion. The silver plating makes soldering much easier. Next, you'll need a high wattage soldering iron. I like to use a 45-60 watt iron. A soldering gun won't cut it. You need to heat the connector up as fast as possible to avoid damage to the coax.

A good grade of solder is also important. I use a low flux solder by Kester™. It's called the "no clean 245." Digi-Key™ handles it. The Digi-Key catalog number is KE1400-ND, and it costs about ten bucks a pound. With this stuff, there's no big glob of solder flux hanging on the end of the connector after you're done. The connector is not as slimy with flux, either, when you're done.

Don't cheapen up on the inserts required with smaller diameter coax. It makes little sense to spend three bucks on a silver-plated connector and then use a 20-cent insert.

And for reasons known only to some hams, don't reuse old SO-239 connectors. They're just not that expensive, so splurge and get new ones when updating or repairing your antennas.

If your plans include connectors outside, first wrap the connector with a layer of black electrical tape. Then apply a layer of coax seal. That first layer of tape will allow you to undo the connection without trying to clean off the coax seal.

Open wire feed

I use two kinds of open line feed. For temporary installations, I use cheap 300-ohm TV line. This stuff is great for Field Day! I also use 300-ohm TV line when

testing new antennas. Of course, this assumes the antenna requires open line feed. Although I know there will be some difference in performance between the 300-ohm and 450-ohm feed, it will be fine for a test or two. At the home station, I use 450-ohm ladder line. I can tell you to get the stranded type and not the solid. The stranded line is *so* much easier to use.

If you use ladder line, check the connections at the top of the tower. It's not uncommon at all to have one side of the ladder line break off. That's why it's best to use some sort of hanger to support the line from above.

Use TV-style standoffs to keep the ladder line away from the tower legs. Don't overlook the aluminum spouting and siding. Newer homes use all-plastic downspouts and siding, but check anyway.

It's the little things

While you are out working on the antennas, check any balun(s) you may have in your system. Although you can't do much in the way of electrical checks, give them a good going over with your eyes and fingers. I've never come across a water-cooled balun, so if your balun sounds like a half-filled bottle when you shake it, trash it! Check for loose-fitting hardware and broken wires. Make sure the connector is dry and fully encased in coax seal. Retape and reseal if needed.

How many coax switches do you have? Check them for proper operation. One very old Heathkit switch I had developed a low resistive short to ground on two outputs. Opening the switch revealed a splatter contact or two. Perhaps the switch had taken a lightning strike.

If you put in new coax or open line feed, how about making up some new jumper cables? If you're like Randy KD8JN, you'll need some RG-8 cable to connect the Argonaut 515 to the SB-220. But those are usually way too large and bulky for most QRP rigs. Some of the micro rigs aren't heavy enough to hold the coax down on the table, so don't forget to make up some RG-8 mini cables, too.

Don't overlook your ground system. Many QRPers don't even have a good RF (or DC) ground in their shacks. That's wrong. If for nothing else, it's a good safety feature and is required in most cities. Check the connection between the ground rod and the cable connected to it. It's possible the cable has corroded through. Tighten up any clamps on the grounding rods. This is especially true if you live in California. Those earthquakes have a tendency to loosen up just about everything.

I prefer to use the braided copper straps for ground runs. This stuff is very flexible and easy to work with. Copper ground bus strips are ideal, too. They allow you to connect all your equipment together. Don't daisy-chain your grounds together—you'll open up the possibility of ground loops. Use a single-point ground (see **Fig. 2**). And for goodness sakes, don't ground your gear to the gas pipe. The sewer pipes are another no-no. Also, don't depend on the ground or common wire inside your electrical service.

Mike's dream system

Right now, as I type this, my new shack is nothing more than a very expensive muddy hole in the ground. As spring approaches, things should start to take shape. So, here are my plans for my QRP shack.

For openers, I plan to install a 60-75-foot free-standing tower. The 10-foot difference between 60 and 70 feet is very costly. The tower should be able to hold 20+ square feet of antennas.

For 20 through 10 meters I decided on a log periodic array. For weak signal two meter work a 17-element boomer is planned. Also on two meters will be a Ringo Ranger for repeater use.

I'm planning a solar-powered weather system on the south forty. This will be linked into the Skywarn network via packet, so a small vertical antenna will be installed just for this weather system. Right now, this idea is still very much in the planning stage.

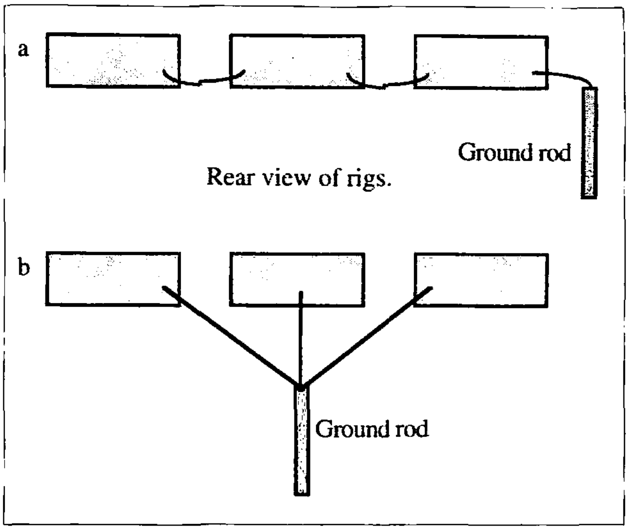

Fig. 2. a) The wrong way of grounding your station equipment; b) A better way of grounding. This is called single point grounding.

On the low bands, a full-wave 80 meter dipolc up at the 60-foot mark on the tower. For 40 and 30 meters, there will be centerfed zepp antennas fed with open line feed. Since there are no trees on the land, these dipoles will be configured as inverted "vees."

My only problem so far is finding a way to pay for all this stuff! On the other hand, it costs nothing to dream.

Next month I'll give you the information about the Four Days in May QRP forum to be held again at the Days Inn during the Dayton HamVention.

HAMS WITH CLASS

Staten Island NY 10313-0006

Blast Off With Exciting Activities

Every year, one of the favorite enrichment units in our ham radio class is the one we do about the space program. Maybe you can't always be speaking with one of the astrohams, or maybe your school won't get picked to participate in the SAREX program, but you certainly can provide a stimulating and exciting series of activities involving space and communications.

Twenty-eight years ago, on July 20, 1969, an estimated one billion people around the world—a quarter of the Earth's population—watched the first manned moon landing on television. If your students can learn about the Apollo 11 mission and the moon, they'll come away with a sense of the mission's impact on their lives.

Plan your research strategies well before you introduce this unit of study. Work with your school's librarian as well as with local library personnel. Help gather videotapes, newspapers, magazines, and documentaries to be made available. Be sure to check out organizations that will have materials available for classroom use, such as The Young Astronaut Council, with its Young Astronaut Program and Young Astronaut Clubs. They can provide information, curriculum materials, activities, and lots of ideas for your Apollo 11 and other space-related school projects (**Photo A**). Contact the Young Astronaut Council at 1308 19th St. NW, Washington DC 20036; (202) 682-1984.

"Ellie Van Winkle NØQCX and her husband Rip NVØM created the BARC Jr. club for youngsters interested in ham radio."

NASA Teacher Resource Centers in 11 locations around the country offer educational videotapes, slides, audio tapes, publications, teacher guides, and more. Call the NASA Goddard Space Flight Center Teacher Resource Laboratory at (301) 286-8570 to get the location and phone number of the center nearest you.

Photo A. Seventh graders James and Matt enjoy space-related activities like building dioramas.

For a 26-minute video of the Apollo 11 mission contact NASA Center for Aerospace Information at (301) 621-0390.

One fun activity you can do with your class is to have them write the famous sayings associated with the landing. Talk about those famous quotations and what they mean. Why is each quote so memorable? Then have the students put themselves in the place of each author. What would they be seeing, hearing, and feeling? Make a chart and have the children add their own quotes (see **Table 1**).

Event	Famous Words	My Famous Words
The moon landing	"Houston, Tranquility Base. The Eagle has landed." (Neil Armstrong)	
The first step on the moon	"That's one small step for a man, one giant leap for mankind." (Neil Armstrong)	
The plaque	"Here men from the planet Earth first set foot upon the moon. July, 1969 A.D. We came in peace for all Mankind." (NASA)	
A description of the moon	"Beautiful! Beautiful! Magnificent Desolation!" (Edwin Aldrin)	
Presidential phone call to the astronauts	"Because of what you have done, the heavens have become a part of man's world. For one priceless moment in the whole history of man, all the people on this earth are truly one." (President Richard Nixon)	

Table 1. Do-it-yourself quotation chart.

A good magazine to subscribe to for your classroom is *Odyssey*, published by Cobblestone Publishing, Inc., 7 School St., Peterborough NH 03458. Copies of the issue titled "Magnificent Moon" may still be available. Call (800) 821-0115.

It's also fun to have the kids bring in models they've built. Commercial plastic model kits of the Command Module, Lunar Module, and Saturn 5 rocket (stock numbers 5083, 5081 and 5082, respectively) are available at local hobby stores from Monogram Models. Have fun!

Ham Radio Family Night

Like most hams, one of the things I like best about going to the Dayton HamVention every

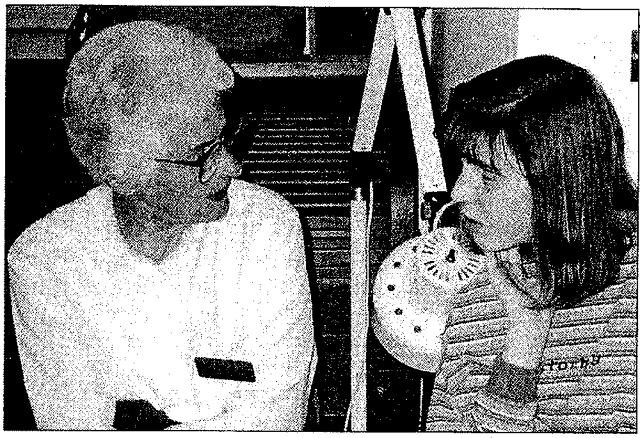

Photo B. Elmira Bebe Greenlee KDØGE elmering Tracy Shelton (now KBØBX) for her Novice license. Photo by Ellie Van Winkle NØQCX.

year is making so many new friends. I met Ellie Van Winkle NØQCX from Boulder, Colorado, nearly five years ago at Dayton. She is a retired kindergarten teacher, and she and I bonded instantly. Ellie and her husband Rip NVØM created the BARC Jr. club for youngsters interested in ham radio (**Photo B**).

Over the past few years, the Van Winkles have become good friends who share all of BARC Jr.'s activities with me. With their tremendous efforts, and the help of interested parents and other club members, they have provided me with some of the best presentations at the Dayton Youth Forum in the past four years. For Dayton HamVention '96 they outdid themselves by training and bringing the BARC Jr. Dayton Team to do a presentation. The children had a roundtable discussion about why their club was so successful and how they managed to raise money to come to Dayton. It was a wonderful and informative presentation.

Last month, Ellie sent me a videotape of the BARC Jr. Family Night. There are so many good things that come out of a night like this that I decided to share it with the readers of this column. Certainly modifications to suit individual club needs should be considered by any club with a growing number of young people in it. It's important for the children coming into amateur radio to know that they are welcome and that they are encouraged to participate.

"The children explain to their families all about Field Day, building kits, and foxhunts, and speak proudly of their accomplishments."

Why a "Family Night"?

The purpose of the club's Family Night is to share the BARC Jr. activities with other family members. It provides a chance to enlighten parents about the ham radio teaching program, the progress of their children, and to introduce them to the Elmers and Elmiras who provide the instruction. Ellie also likes to have the parents get an understanding of the value of the hobby to young people.

After three years of operation with BARC Jr., the Elmers and the children felt a need to share with the involved families what and how the kids learn, and why the kids and Elmers so enjoy getting together each Saturday at 2:00 p.m. for one and a half to two hours.

According to the Van Winkles, and what I observed on the tape, the children really enjoy Family Night. It gives them an opportunity to discuss community service activities, share stories about speaking around the world, tell about their young ham net and foxhunts, and talk about learning CW and theory. The children explain to their families all about Field Day, building kits, designing and building antennas and fund raising projects. They also speak proudly of their wonderful presentations at the Dayton Youth Forum and of how to get more youngsters into the hobby.

As seen through Ellie's eyes, the value of a Family Night comes from:

1. Educating the families about their children's activities and gaining an appreciation of the dedication of the adults who provide the instruction.

2. Cross education—parents educating one another, kids educating other kids, and parents, kids, and Elmers all educating each other in a variety of ways.

3. The socialization aspect—the getting together of everyone with the children's best interests at heart is extremely valuable.

4. Family Night helps parents, kids and Elmers evaluate possible candidates for the Dayton Youth Forum, as well as for local speaking engagements.

By sponsoring the very successful BARC Jr. group, the Boulder Amateur Radio Club has provided the rest of us with an excellent role model. Getting youngsters caught up in the excitement of wholesome and stimulating activities with adults can only have positive ripple effects which will keep going on and on for years to come. I am delighted and proud to feature the outstanding work of this group. I know we all wish them continued success. See you at Dayton!

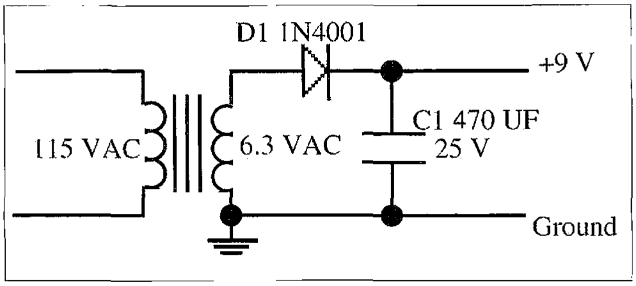
UPDATES

Danger!

In "Build This Receiver Preamplifier," which appeared in the January issue, beginning on page 26, there are a couple of weird glitches in the schematics. One of them could be dangerous to the builder.

Most importantly, **Fig. 4** should look like this:



The transformer is not supposed to have connections from the transformer primary to the secondary. This is a dangerous error and could cause serious problems if built the way it is shown in the January issue.

Then, the other points. In **Fig. 1**, the unidentified resistor in the lower left (from **Q1** to ground) should be **R2** (5.6k). **C5** should show a connecting dot to **+9V**, and the device identified as "**02**" is actually **Q2**.

Finally, in **Fig. 3**, the words "flat side down" were omitted. We apologize for these errors.

Enhanced Schematic

Also in the January issue, in N4UAU's "Enhanced Automatic Voltage Controller" we have a few things to straighten out. On page 42, in the schematic:

Pin 3 should not be connected to ground. If it is built as shown, there will be a big puff of smoke and one very unhappy builder.

The unlabeled resistor by **T1** is **R11**.

The unlabeled resistor near **C1** is **R15**. It has a value of 0 for the Bar Mode and 360Ω for the Dot Mode.

On page 45, in the Parts List, the values for **R4** and **R5** are reversed.

J. Frank Brumbaugh KB4ZGC also brought something to our attention from the same parts list—all resistors should not be 1.4 watt; they should be **1/4** watt. This was a computer translation error, but we apologize for any confusion.

HE'D RATHER OPERATE "MOBILE-IN-MOTION" THAN HAVE TO SIGN "PORTABLE"

DEPARTMENTS

HAM RADIO FUN SECTION

On the cover: Northern Kentucky QTH of proud owner Jim Brown AE4EY features 45-foot, crank-up, tilt-over, all-aluminum Aluma-tower; 5-band, 2-element HF quad by Lightning Bolt Antennas: 4-element 2m quad, also by Lightning Bolt, nested inside the HF quad; 2m Cushcraft Tingo atop the mast; multi-band Radio Works Carolina Windom supported by a cross-arm from the tower in a flat-top configuration; and (whew!) Cushcraft R7 multi-band vertical mounted on top of a fence off to the right. The tower is mounted on a tilt-over base and raised and lowered via a cable through a pulley attached to the chimney and then fastened to a car bumper. (Another tower-pulley-cable tale—involving insurance—appears on page 84.)

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateur Radio Today*, 70 N202, Peterborough NH 03458-1107. 73 Amateur Radio Today is owned by Shabromat Way Ltd. of Hancock NH.

NEVER SAY DIE

Wayne Green W2NSD/1

The Handwriting

A couple of things almost got me to thinking. One was a well-considered letter by Ken W8VWZ wherein Ken made a very good case for those who believe that keeping the code test as an obstacle to keep new hams from joining our fraternity is sounding the death knell for amateur radio. The other was a review of the license statistics over the last ten years.

I did a hasty addition of the number of Extra/Advanced/General licenses as a percentage of the total licenses and found that the percentage of encoded hams has been dropping steadily, dropping from 61.6% in 1986 to 44.2% in 1996, and this was a straight curve drop. If I then subtracted in the number of hams who have dropped out of the hobby, either from a lack of interest or through death, which the FCC's ten-year licensing system ignores, the percentage is more like 38.8%, and that brings us to our having about 16% HFers in ten more years—unless we make some serious changes. I have seen no hint of any proposed changes coming from the ARRL. Have you?

And we'll be down to 10% in 13 years! Well, that'll certainly reduce the QRM on the HF bands!

This drop in HF hams explains why so many ham radio stores have been going out of business, and why the manufacturers of HF equipment have been having such a tough time. Our new no-code hams have an average ham station investment in the hundreds of dollars, while HFers tend to be more in the thousands.

I don't know how much of a difference getting rid of the code requirement might make, but polls of the no-coders tell us that this is the main obstacle to their upgrading. And considering the potential for us to lose our UHF and VHF bands, Ken could well be right that the Old Guard intransigence on maintaining the code barrier will be the death of amateur radio.

Sure, the Internet is already making DXing easier than fighting the QRM on 20m. And the profusion of commercially made ham gear has discouraged building, which has, in turn, made our access to parts more difficult. But we still have a world of adventure to offer the motivated.

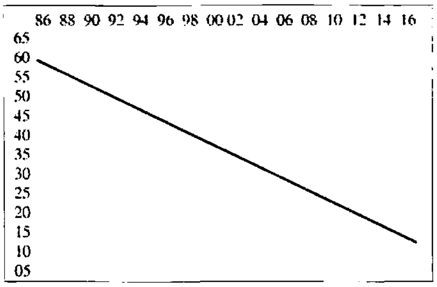

Fig. 1. Here's the percentage of General/Advanced/Extra Class (code barrier) licensees plotted from 1986 to 1996. This projects to about 8% by 2016, unless the code barrier is removed or the hobby is discontinued as no longer relevant. The ARRL destroyed the American ham industry and our recruitment of youngsters 30 years ago; now they're destroying the hobby and themselves. I wish I were exaggerating.

More Bio-E News

An Ohio reader who's been using the Bioelectrifier (*73*, May 1996) reports more black hairs on his head, teeth and gums improved, the first improvement in his nearsightedness since early childhood, better night vision, improved elimination ("It feels great to be normal for the first time in 72 years!"). I'm getting similar health improvement reports from around the country. Even if all these are just the placebo effect, it's still worth the time and trouble. Have you built one yet?

Now I realize that most Americans have been reduced to gutless wimps by our compulsory school system, but a few hams seem to have survived the 12 to 16 years of brainwashing with their sense of curiosity not totally destroyed, so I have hopes that the Bioelectrifier, which may turn out to be the medical industry's worst nightmare (an inexpensive cure for expensive illnesses), will get a fair trial. In the meanwhile, we can expect the usual ridicule, denunciation and persecution of the pioneers.

Yes, there are some commercial suppliers of the plant growth stimulator for those for whom even this simple device is too much to whip together.

Will this simple gadget be able to cure AIDS, and help rebuild immune systems to counter cancer, lupus, Lyme disease, and a bunch of other illnesses? Well, I don't yet believe in miracles, but I'll be surprised if almost any chronic illness can't be cured by a combination of stopping the input of poisons into the body, providing it with the nutrition it has been designed over millions of years to work with, with some help from the Bioelectrifier, and maybe some magnets, as we learn more about how they work. Oh yes, add in some prayer, because that has been proven to help. And a reduction of stress, since every illness has a psychological component. If we treat the body right we should be able to get another 20-30 years of good dependable service out of it over today's average.

The Freon Hoax

Congress has done it to us again! Did you get sucked in, as did Congress and President Bush, on the Freon hoax? Remember all that total hogwash about Freon eating up the ozone. Well, just by the damnedest coincidence this brouhaha, pushed by the greenies, came along at the same time as DuPont's patents for Freon were expiring. Talk about serendipity! Talk about billions of dollars in profits!

Freon can no longer be made since our beloved government now classifies it in about the same category as cocaine. So now a new and less efficient refrigerant is being used. Care to make a wild guess as to what company owns the patents on it? Oh, you peeked.

It turns out that scientists tell us that Freon leakage was environmentally insignificant since the chlorine molecule involved is heavier than air and sinks instead of rises. The evaporation of sea water releases infinitely more chlorine. Maybe Congress can put a stop to that by desalinating the oceans.

Yes, and by another unbelievable coincidence, DuPont is a major contributor to greenie groups. Who says altruism doesn't pay off? Big! I defy you to cite any major corporate altruism that isn't profitable.

Congress is driven by big business, and big business is driven by profits, even if they have to bribe a few greenies along the way to help move Congress in the "right" direction. As I've mentioned, every industry I've gotten involved with has turned out to be crooked, once I got to know the players. Capitalism is the best system we've found, but it sure isn't perfect.

Well, you keep re-electing Congress, so smile when you are paying the bill for a Freon substitute.

School Costs

There are several benefits we expect to derive from being a citizen of a country. Like a set of laws and their enforcement which help us to live in peace with each other. Like protection from foreign attack. Like an infrastructure which allows us a good lifestyle. That might include services such as sewer, water, power, roads, food supply, clean air, law enforcement, firefighting, and so on. These are

Continued on page 38

LETTERS

From the Ham Shack

Les Hale W3LIV5. The December article by W8AHB on Nikola Tesla was certainly on the mark; he was clearly a great genius. As a licensed amateur for over 50 years, and electrical engineer for 44 years, I have never thought there was any argument about this, having learned his "rotating field" concepts in college in the early 1950s. I have always thought it was common knowledge that he was "right" and Edison "wrong" in the AC vs. DC debate.

However, I would question the need to knock Edison down to build up Tesla's reputation. Although not possessing the theoretical insights of Tesla, Edison did many notable things by applying the principles outlined in "A Perspirational Message" by W2NSD/1 in the same issue. It would appear that today this approach is still leading to advances in electrical science and engineering, although it is perhaps more widely used now in Japan where they still frequently take the approach of learning from everybody and trying everything to make new discoveries. Perhaps Tesla has suffered somewhat from the "mad scientist" image and the fact that he made one serious mistake in his ideas about the wireless transmission of power. I believe this is not quite as crazy as most people think, and could have been possible if the losses in the semiconducting region between the insulating lower atmosphere and conducting ionosphere had turned out to be much less. Actually, to get reasonable efficiency, the "Q" of the spherical cavity between the earth and the ionosphere would have to be extremely high. "Schumann resonance" measurements have shown this Q to be about 5, but Tesla could not have known this.

A "lossless" cavity would have had other implications for hams. Signals which easily propagated around the world many times would certainly lead to untenable QRM and "echo" effects, and entirely different communications systems would have evolved.

Orlo Hudson W5LVA. I am a long-time lifer reader. This is to suggest that you research and publish an article which will probably make that issue a collector's item.

I left 20m AM phone about 30 years ago and have been on 2m ever since. Now that I am retired, I would like to dust off some of that old equipment and put it back on the air, but there have been so many band changes and new services that I really don't know what bands I can work and what modulations are legal. I have an old Class A license—which they now call Advanced. I am not about to "upgrade." I was licensed in 1941!

How about publishing a comprehensive spectrum analysis of places where hams (not appliance operators) can build equipment, operate the equipment, and explore the science without being illegal.

Include all frequencies—not just the established ham bands. For example, the frequencies below 100 kc.

While you are at it, you might comment on these proposed projects: (1) A small linear amplifier to hang on a VCR and boost the channel 3/4 output to where it can be picked up throughout the house. How much power can you legally run? (2) A 1 kW transmitter centered on 1 mc, putting out true Spread Spectrum Modulation. The FCC can't receive the rig unless they are standing under the antenna with an untuned FS meter.

I am just full of such ideas, but I don't want to go to jail! I am not interested in a "rag chew" on some appliance; I want to build something different and test it...

Dennis L. Foster KK5PY. Thank you ever so much for such a great, unbiased, amateur radio magazine. I had been inactive in ham radio for years and had really forgotten what a great publication it is until I read a copy or two from a friend's collection.

Les Warriner WA7HAM. History Lesson—Battle Of Agincourt. The French, who were overwhelmingly favored to win the battle, threatened to cut a certain body part off of all captured English soldiers so that they could never fight again. The English won in a major upset and waved the body part in question at the French in defiance. What was this body part? The answer, which clears up some profound questions of etymology, folklore and emotional symbolism, is that the body part which the French proposed to cut off of the English after defeating them was, of course, the middle finger, without which it was impossible to draw the renowned English longbow. This famous weapon was made of the native English yew tree, and so the act of drawing the longbow was known as "plucking yew." Thus, when the victorious English waved their middle fingers at the defeated French, they said, "See, we can still pluck yew!" Over the years some "folk etymologies" have grown up around this symbolic gesture. Since "pluck yew" is rather difficult to say (like "pleasant mother, pheasant plucker," which is who you had to go to for the feathers used on the arrows), the difficult consonant cluster at the beginning has gradually changed to a labiodental fricative "f", and thus the words often used in conjunction with the one-finger salute are mistakenly thought to have something to do with an intimate encounter. It is also because of the pheasant feathers on the arrows that the symbolic gesture is known as "giving the bird." And yew all thought yew knew everything!

One of the perils of E-mail is being spammed with plucky stuff like this. However, it does answer a question I never thought to ask... Wayne.

Ron Hartoebben KBØPF. I received the current issue of *Cold Fusion* today and noticed your E-mail address. How have I missed that before, since I subscribe to *73* and *CF*? I recommend that you encourage E-mail submissions for your magazines. Publish your address more often. Maybe even develop a Web page. It should pay off for you. After all, you're already on AOL.

I enjoy your editorials. I use ideas from them often in my courses. Yes, I am a teacher (in a small parochial elementary school). I started teaching because I can afford to after retiring from another exciting profession.

The fellow who helped me most in ham radio was Bill Stocking WØVM, who wrote several articles for you. We used to test some of his antenna theories at my shack. I successfully encouraged him to try phone in lieu of his exclusive CW, and in his last few years he enjoyed all aspects of the hobby.

I am in the middle of three generations of ham radio, all in-laws. My father-in-law got his ticket in 1930 and is still active. We have great photos from his early ham days. My two sons-in-law are both hams and making names for themselves. My experiences have paralleled yours often. Even did a stint as local publicity director for Mensa.

Recently I helped a fellow develop a database for WW2 submarine vets and even found a couple local guys who were on the *Drum*. I hope someday to catch one of your talk show appearances. You ought to give some advance notice in your magazines, or better yet put it in your Web page. There I go again, giving you advice.

Number 21 on the list of my 73

most urgent projects is setting up a Web page... Wayne.

Bill Chatterly N1SGI. "Why do I have to study CW? I use SSB rarely, no RTTY, no SSTV, no repeater, no computer—I only use HF. 1 do not care what a resistor or a capacitor does."

I had to learn this as a requirement to get my license for HF. It is part of the hobby. Is not CW part of the requirement also? What shall we delete from the requirements next? Think about it. Good luck, FISTS!

Guy A. Matzinger KB7PNQ. One hundred fifty years ago the Russian liberal thinker, Alexander Hertzen, wrote that what he feared most was a "Genghis Khan with the telegraph." When Lenin seized power in Petrograd in 1917, his first objectives were the seat of government and the telegraph office.

When, several years ago, "Incentivised Licensing" defined the course of amateur radio, it became the central control and essence of the hobby—using telegraphy and high-speed code tests to decide operating privileges. This totalitarian control with its enormous ability to manipulate amateur radio has become increasingly static. However, opening shots in a war over who gets to dominate the hobby were fired in recent months. At issue is who shall control international rules and regulations for amateur radio—specifically Morse code testing. Those organizations who believe they are the icons of order—or each country?

With sphincter-tightening apprehension, pro-code advocates are lobbying and bullying the international community, warning of chaos and a possible collapse of amateur operations if Morse code testing requirements are removed as a *treaty* obligation. These mutterings hint that the established foundation of the hobby will be eroded if each country is allowed to set its own code testing standards—absurd—each country does that already. The real concern is that some democratic society may not want a code test for any class of license.

We must move away from the mental virus that Morse code is the basis that defines an amateur radio operator—as we moved, 60 years ago, from crank-starting a Model-T Ford to today's fuel-efficient cars. Pro-code organizations and media pundits, who support the closed-shop mentality of limiting participation, need to stop whining with nostalgia for a vanished world, implying that without a Morse code treaty requirement amateur radio is going to turn into a disaster. Denmark recognized the need to change and in July of 1996 reduced license classes from five to three and code testing to 5 wpm for any class of license. Once again the Danes lead the way—without calamity.

Have we become so accustomed to our freedoms being worn away by self-serving interest groups that we can no longer allow any other country to choose its own course of action? The value of democracy lies in its freedom to choose. Amateur radio operates as a microcosm of society and if it wishes to be a communications participant, and continue free use of the spectrum and all the valuable progeny of that gift, it must change. The dynamic future of this hobby depends on integrating tomorrow's technology with today's abilities.

If ever there was a case for social justice, eliminating international Morse code *treaty* requirements tops the list. I strongly urge each of you to write to: IARU FASC, c/o IARU International Secretariat, PO Box 310905, Newington CT 06131-0905—supporting the removal of Article §25.5 at WRC99 as a *treaty* obligation of administrations and the putting of fun back into amateur radio. Then, perhaps, we can have a secure tomorrow for the hobby. 73

Help Wanted: Dayton Youth Forum

New York City—Educator Carole Perry WB2MGP will be moderating the popular Dayton Youth Forum on May 17th. She is looking for articulate, enthusiastic young people (8–18 years of age) who would like to be presenters. Please call Carole at (718) 761-5733 as soon as possible.

Scholarships for Amateurs

The Foundation for Amateur Radio, Inc., a nonprofit organization with headquarters in Washington DC, plans to administer 60 scholarships for the academic year 1997–1998 to assist licensed radio amateurs. The Foundation, composed of over 75 local area amateur radio clubs, fully funds five of these scholarships with the income from grants and its annual hamfest. The remaining 55 are administered by the foundation without cost to the various donors.

Licensed radio amateurs may compete for these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled in or have been accepted for enrollment at an accredited university, college or technical school. The awards range from $500 to $2,500, with preference given in some cases to residents of specified geographical areas or the pursuit of certain study programs. Amateur radio operators, especially those in DE, FL, ME, MD, NJ, OH, PA, TX, VA and WI, are encouraged to apply.

Additional information and an application form may be requested by letter or QSL card, postmarked prior to April 30, 1997, from: FAR Scholarships, 6903 Rhode Island Ave., College Park MD 20740.

The Foundation for Amateur Radio, incorporated in the District of Columbia, is an exempt organization under Section 501 (C)(3) of the Internal Revenue Code of 1954. It is devoted exclusively to promoting the interests of amateur radio and those scientific, literary and educational pursuits that advance the purposes of the Amateur Radio Service.

Found in Penn Wireless Assn.'s *X-Mitter*, January 1997.

FCC Enacts Internet Morse Code Requirement

The FCC, under pressure to clean up the Internet—especially after the Communications Decency Act provisions regarding Internet content regulation were stricken as violating the US Constitution—has decided instead to create a Morse code requirement for Internet users.

Citing the success of the Amateur Radio Service and the general belief that its requirement for operators to pass a Morse code proficiency exam and other technical requirements has kept the ARS "clean," the FCC has decided to enact a 5 wpm requirement for all Internet users. They are leaving open the issue of whether there should be a "codeless" class of Internet user and are soliciting comments on the proposal. Presumably, a "codeless" user would be restricted to Web pages published by household magazines and kitchen equipment suppliers, for example.

Persons wishing to develop Web sites that have actual content, as compared to just links to other Web sites, must pass a 20 wpm Morse proficiency test in HTML and the Java programming language, and show that they have mastery of at least one human language such as English or Esperanto.

The FCC, which lacks budgetary authority to implement the testing program, has stated that it intends to create Volunteer Examiner programs for Internet applicants.

From the *ARNS Newsletter*, February 1997; originally in *The Long Wire*, November 1996; special *merci* to French Ministry of PTT spokesman A. Prel FØOLE.

Hams on Duty in Western US Flooding

Ham radio has pitched in to help in the wake of serious flooding in the western US. In California, flooding 50 miles north of Sacramento resulted from a week of torrential rainfall. Tim Tribble JD6MDV, of the Sacramento CA City Fire Reserve RACES Operations Center, reported that his group was activated at noon on Friday, December 27th, and had been on 24-hour duty for an extended period thereafter. RACES operators have provided supplemental communications for the Fire Department, including relaying information about water levels at area dams. The hams also have been providing support services, and have even delivered food to out-of-state mutual aid groups.

Tribble reported that up to 40 area amateurs had been manning the command post. Other command posts were located at the Wilton Fire Department and at Station 59 in the Murietta/Sloughouse area of California.

One Saturday, seven operators were dispatched to the city of Marysville to assist the Department of Fish and Game in assessing livestock care needs. Another 10 were sent to aid the Red Cross in damage assessment.

Ham radio has also been assisting in flood recovery efforts in the northwest, including Oregon, Washington, and Nevada. In Oregon, long-distance telephone service to the Ashland-Grants Pass vicinity in the extreme southwestern portion of the state went down when a fiber optic cable was severed. Ham radio took over, linking the county via HF with the state emergency operations center in Salem. Oregon SEC Lew Williams WD7NML said Jackson and Josephine counties were the hardest hit. In Jackson County, hams helped provide communication at shelters. Williams said hams also pitched in during sandbagging operations. In Nevada, Dick Creley KJ7UK of Gardnerville reported hams were activated on New Year's Day and provided secondary communications for the Douglas County Sheriff's Department, the Emergency Management Office, and two shelters that housed some 50 residents. The approximately 30 hams in Douglas County and Carson City put in a total of 350 work-hours. Creley said damage was extensive, and the cities of Minden and Gardnerville were isolated. Bruce Pfeiffer N7CPP of Carson City said telephone service remained in operation, limiting the need for ham radio communication support. His wife, Sue Pfeiffer N7PRF, and Reed Ross W7HOP manned a station at the Carson City EOC, while he and Jo Ann Paul N7MBM, manned a station at a local Carson City shelter.

In Yerington NV, 17-year-old Carrick Dunn KB7OBE provided the only communication link between his town and the outside world.

TNX *The GCARC Wireless*, January 1997.

ARLSØ16 Ham Radio on Space Station

A foundation has been laid to give amateur radio a permanent presence in space. Late last year, amateur radio delegates from eight countries—Russia, Japan, Germany, Great Britain, Italy, Canada, France and the US—met at the NASA Johnson Space Center in Houston TX to map plans to include a permanent ham radio station aboard the International Space Station, to be tended by station crew members.

From the United States, members of the SAREX Working Group, officials from NASA, US representatives of the Russian *Mir* Amateur Radio experiment and members from the Johnson Space Center Amateur Radio Club attended the meetings November 4th and 5th, chaired by Roy Neal K6DUE. ARRL Vice President Joel Harrison W5ZN (ex-WB5IGF) represented the League at the gathering. SAREX Working Group member Rosalie White WA1STO, of the ARRL Headquarters staff, was among those on hand. The delegates jointly developed a draft memorandum of understanding to promote the development of Amateur Radio on the International Space Station—to be known as ARISS.

The ARISS group will provide for the planning, coordination and performance of amateur radio projects on the space station, similar to the way the SAREX Working Group currently coordinates amateur radio activities on many space shuttle missions. AMSAT and IARU organizations in each of the eight countries are to review and consider approving the memorandum of understanding. In the US, this includes AMSAT-NA and the ARRL

The AMSAT-NA Board unanimously approved the memorandum of understanding at its November 11th Board of Directors meeting in Tucson AZ. Once the memorandum is finalized, AMSAT-NA President Bill Tynan W3XO has been given authority by the board to sign it. AMSAT-NA Vice President for Manned Space Frank Bauer KA3HDO congratulated the international ARISS team for a job well done. "We look forward to a truly cooperative international venture on the International Space Station," he said.—de ARRL HQ, via Keith N3LDF.

The Hale-Bopp Comet and Its Controversial Tale

Build the Cosmic Crystal Set and listen in!

Thomas M. Miller WA8YKN
314 South 9th Street
Richmond IN 47374
E-mail: thomil@infocom.com

April 1997 marks the closest approach of the long-awaited Hale-Bopp comet, discovered on July 22, 1995 by amateur astronomers Alan Hale and Thomas Bopp. Although comets are notoriously unpredictable, this one shows every sign of becoming a bright, naked-eye object, perhaps even visible in the daytime! At the very least, the arrival of Hale-Bopp will be an event to remember.

Brightness, however, may not be the most interesting aspect of this object. Riding with Hale-Bopp is an intense storm of rumors and controversy which seems to intensify in direct proportion to the comet's proximity.

The first indication that Hale-Bopp was an "unusual" comet was its discovery: most comets are discovered only a few months away from their closest approach to the sun. The comet Kohoutek set a record in 1973, first seen seven months out. Hale-Bopp was first spotted an incredible 21 months away from Earth, an astounding 666 million miles out, beyond the orbit of Saturn! No comet ever discovered would be visible at that distance, even through the largest telescopes in the world. Hale-Bopp, however, was large and bright enough to be seen by *two* amateurs on the *same night... by accident!* Since the discovery, astronomers have searched old photographic plates and discovered that one shows the (then undiscovered) comet, an astonishing 40 *months* away!

"Hams, known to wear hats sprouting antennas, don't embarrass easily, so in this case it's clearly up to us."

Not only does Hale-Bopp appear to be the largest and brightest comet ever discovered, but its behavior defies explanation. The comet is far brighter than it should be at that distance from the sun, and it has regular outbursts of brightness, accompanied by huge jets of gas, dumping carbon dioxide at the rate of several tons per second. These outbursts occur every 19 days.

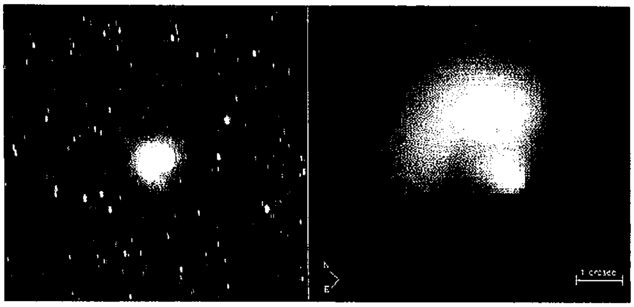

Photo A. The HaleBopp comet as seen by the Hubble space telescope on September 26, 1995.

The controversy surrounding Hale-Bopp really began to heat up on November 16, 1996. Chuck Shramek, radio host and amateur astronomer, released a photograph of the comet which clearly showed a large object moving with Hale-Bopp. This object was round and sharp, with a curious "line" through it that made it resemble the planet Saturn with the rings on edge. The image soon found its way onto the Internet, and all "Hale" broke loose!

Chuck was immediately and savagely attacked and denounced by astronomers everywhere, who claimed that the object in question was an 8.5 magnitude star, and the "line" was a diffraction spike caused by the optics in Shramek's telescope. The object in the photograph, however, was clearly brighter than magnitude 8.5, since it was at least as bright as the 4th magnitude Hale-Bopp... and Chuck's telescope does not have a secondary mirror support, and therefore does not create "diffraction spikes" on bright objects. Since that time, other photographs have surfaced from the Japanese National Observatory and others which also show a "companion" traveling with the Hale-Bopp comet.

If Hale-Bopp has a "companion," it would not be that unusual. Most objects in the solar system large enough to have any gravity at all have them. Even the tiny asteroid "Ida" has a companion, a small chunk of rock that orbits the asteroid (although why it was not named "Ho" is a great mystery!). Why, then, does the "Hale-Bopp companion" spark so much outrage and denial among astronomers?

Maybe it's the radio signals!

That's right, radio signals! Starting about the same time as Shramek's photo controversy, rumors of RF emissions

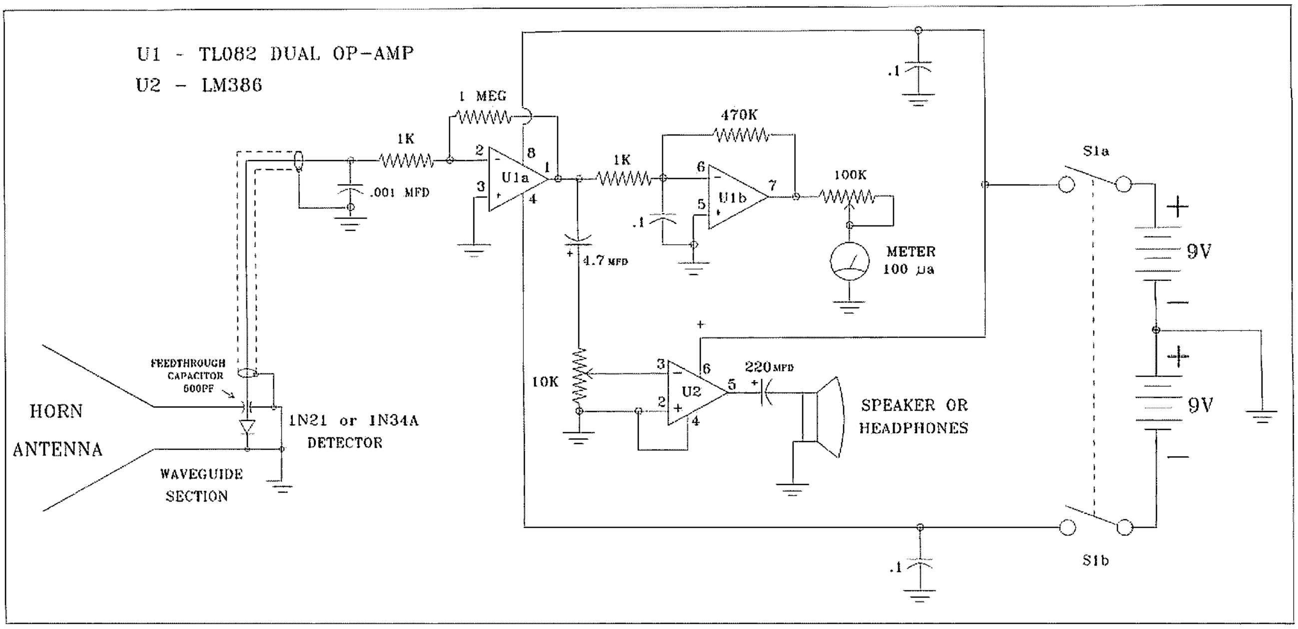

Fig. 1. Schematic diagram for the Cosmic Crystal Set. A sensitive diode detects the microwave signals that enter the waveguide.

from Hale-Bopp began to surface. Some of these emissions were broadband, clearly natural "noise," but others were reported as narrowband, high-intensity signals... *modulated* signals! Radio talk show host (and ham) Art Bell played a tape of one of these signals on the air, and added that a professional astronomer (who did not want his name mentioned) confirmed the reception of "unambiguous signals," not from the comet, but from the *companion!*

As you might expect, this announcement brought the controversy to a new level. Theories to explain the signals began to fly, ranging from some natural-but-unexplained byproduct of the intense gas jets to advanced extraterrestrial beings. Astronomers have refused to comment on the signals at all.

Friends, no professional scientist is going to touch this one, and we can't blame them. Scientists live in a political world, and their livelihoods depend on credibility—and funding. The mere mention of a phenomenon tainted with rumors of "giant spacecraft" and "little green men" assures that they will ignore it. It's a sad fact that, should some E.T. someday fly by and send us some sort of greeting in passing, we might never know, since the professionals would be too embarrassed to acknowledge it!

Hams, known to wear hats sprouting antennas, don't embarrass easily, so in this case it's clearly up to us. Best-selling author Whitley Strieber commented, on the Art Bell show, that hams should monitor Hale-Bopp for radio activity, just as amateur astronomers are observing it optically. I fully agree; whether there are E.T.s involved or not, Hale-Bopp is the most unusual visitor to the inner solar system in our lifetime, and won't return for 3,600 years. We won't get a second chance. Besides, it's a challenge right up our alley, and it sounds like fun!

The "Cosmic Crystal Set"

There has been very little technical information to go along with the Hale-Bopp signal rumors. There have been several references to "K-Band," which only narrows it down to 24 billion possible frequencies. We can, however, make some assumptions: *If* these signals are from intelligent beings, and *if* they are intended for us, then it's safe to assume that they will be easy to receive.

***Photo B**. Is this a hoax? This photo, from an anonymous source on the Internet, shows the Hale-Bopp comet with its purported companion.*

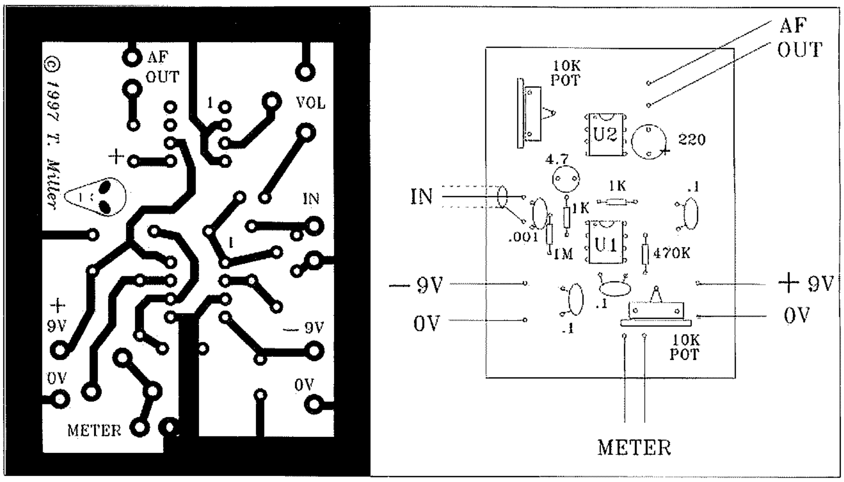

***Fig. 2**. Printed circuit board pattern and component layout guide for the Cosmic Crystal Set.*

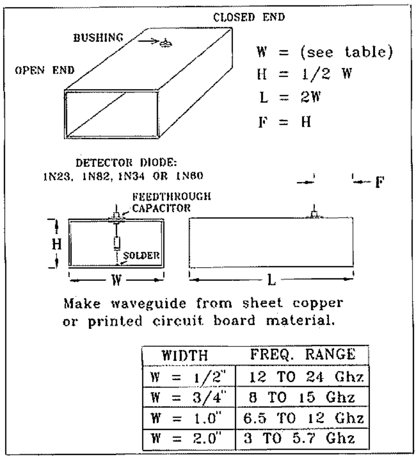

Fig. 3. Waveguide and crystal diode detector construction details.

They would also probably utilize microwave frequencies where antennas behave much like optics, making efficient, tightly focused transmissions possible. Given that, K-Band doesn't sound like a bad choice, but there's no reason not to listen to the entire microwave spectrum, and perhaps UHF and VHF as well. A voltage-tuned TV tuner can sweep from 54 to 800 MHz, and, with the IF displayed on an oscilloscope, makes a sensitive spectrum analyzer. TVRO systems could be used, using the baseband video output to drive a good HF receiver. Surplus radar detectors have sensitive superhet front ends for both X- and K-Band. All these things can, and should, be used—but what if you don't have access to any equipment at all? No problem. You *build* something!

Fig. 1 shows the schematic diagram of the "Cosmic Crystal Set." This simple microwave receiver is nothing more than a sensitive germanium diode detector in a short section of rectangular waveguide. The diode rectifies the microwave energy which is bypassed for RF by a small ceramic feedthrough capacitor. The resultant DC (and audio, if the signal is modulated) is passed to the input of the amplifier.

The amplifier uses a TL082 dual op-amp for two stages of DC-coupled gain. The first stage amplifies the incoming signal, and the second serves as a meter driver. The 100-microamp meter provides an indication of signal strength. If you use a zero-center meter, it won't matter which way you connect the diode across the waveguide.

A 4.7-microfarad capacitor is used to pick off any audio present on the signal, where it is boosted by an LM386 audio amplifier. It can drive headphones or a small speaker. The circuit is powered by two 9-volt batteries.

Fig. 2 shows the printed circuit board and parts layout for the amplifier. The parts are available from Radio Shack™, as well as any good electronic supply house. If there is any interest, I can provide circuit boards for those who can't make their own.

When completed, this device is actually a very sensitive field-strength meter. The only frequency-selective component is the waveguide itself. **Fig. 3** shows the construction of the waveguide, which can be made from sheet brass, copper, or tin. Printed circuit board material works well, also.

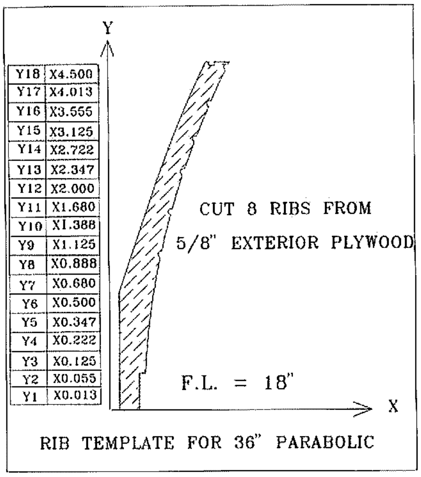

Fig. 4. Rib pattern for the three-foot-diameter parabolic dish. The focal length is 18 inches.

A waveguide is actually a high-pass filter. The cutoff is the point where the wavelength is equal to the width of the guide. Waves shorter than half the guide's width will pass through as well, but the mode of propagation is uncertain, so waveguides are selected in different widths for various bands of frequencies. The table at the bottom of **Fig. 3** shows the proper waveguide width for the different microwave bands. All other dimensions are scaled to this width, as shown. By building one amplifier and a number of waveguide/detectors, it is possible to monitor virtually the entire microwave spectrum.

These waveguides will receive signals of only one polarization, so some method of rotating the horn 90 degrees should be employed to catch both horizontal and vertical signals.

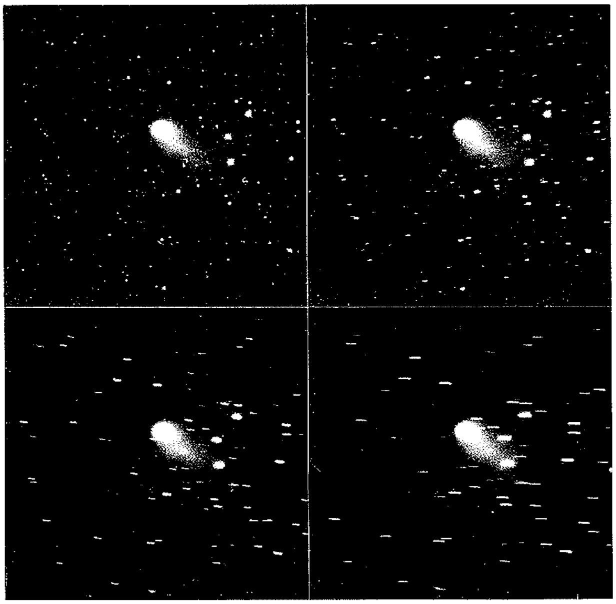

***Photo C**. The Hubble telescope captures the Hale-Bopp as it hurtles toward our solar system.*

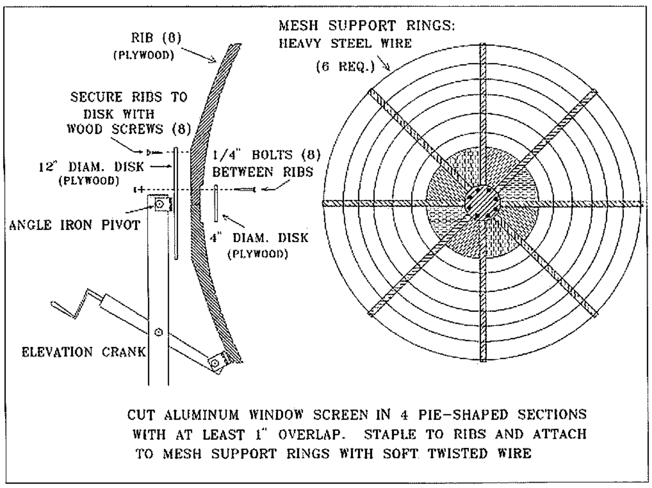

Fig. 5. Construction details of the three-foot dish. The framework is covered with aluminum window screen.

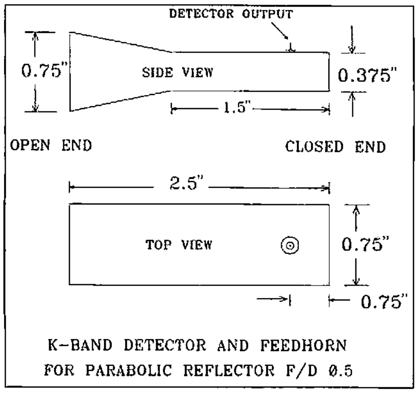

Fig. 6. Dimensions for the K-Band detector and feedhorn. This feed will work with other dishes with a focal ratio of 0.5 to 0.7.

Home-brew microwave antennas

Since diodes have loss, we have to offset this with antenna gain. The most popular microwave antenna is the parabolic reflector. A dish in the 2- to 4-foot range should be ideal for K-Band signals; anything larger would have too narrow a beamwidth to be of much use. **Fig. 4** shows a rib template for a 3-foot parabolic reflector with a focal distance of 18 inches. You can scale this drawing up directly, or lay out your own pattern by plotting the X and Y coordinates from the table and connecting the dots.

Fig. 5 shows how the ribs are assembled to form the antenna framework. The ribs are mounted on a 12-inch plywood disk, while a 4-inch disk is mounted in front. Through-bolts hold the two disks together, providing a strong support for the ribs. I've used this technique for quite a number of antennas, the largest measuring 12 feet.

The feedhorn is shown in **Fig. 6**. Essentially the same as the waveguide/detector shown in **Fig. 3**, the waveguide is extended an inch, while the narrow dimension is flared to match the 3/4-inch width, providing a square aperture. The diode is mounted half a guidewidth from the shorted end. The dimensions shown are for K-Band signals, but can be scaled for other bands.

Sometimes surplus dishes turn up surprisingly cheap, and most often the focal distance of these dishes is very short, making them hard to feed with a conventional horn. **Fig. 7** shows a simple way around this problem: Rather than flaring the waveguide into a horn, the corners of the open end are trimmed back at an angle and a "dispersal pin" is added in

the center of the opening. I've used this to feed dishes with F/D ratios as small as .25 with great success. The beamwidth will vary somewhat with the angle, but 20 degrees seems to work pretty well. For K-Band, a piece of 14-gauge wire will work for the dispersal pin; make it thicker at lower frequencies.

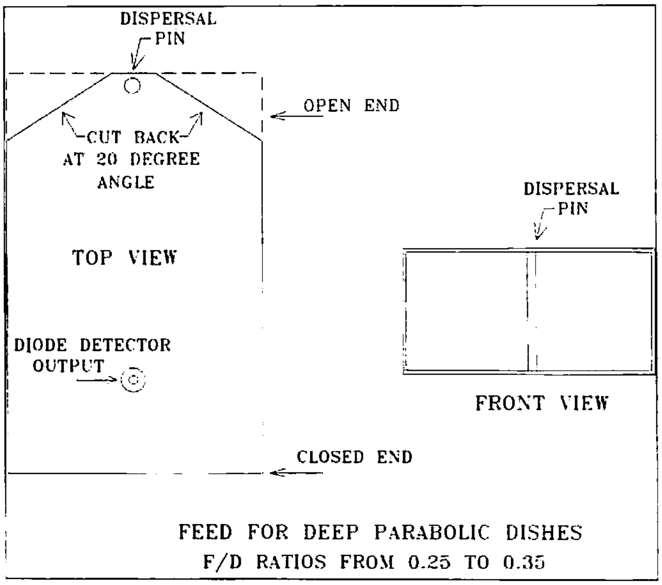

***Fig. 7.** By trimming the open end of the waveguide as shown, short-focal-length surplus dishes can be easily fed.*

All right, you don't have a parabolic lying around, and building one takes too long. Now what do we do? **Fig. 8** shows a simple alternative that anyone can make with a yardstick and a pocketknife. It's a "Giant Pyramidal Horn" antenna, and it can be made from aluminum-foil-backed Styrofoam™, available in standard (4- x 8-foot) sheets at any lumberyard or building supply store. In essence, the horn has as much gain as a dish of the same area, so the 12-inch by 14-inch horn shown might be the equivalent to an 18-inch dish. There is no reason, however, why it cannot be made much larger: Just taper the open end smoothly to whatever size waveguide you are using. The foam can be glued with white carpenter's glue and reinforced with toothpicks. The inside corners can be covered with aluminum tape.

Well, there you have it... simple microwave equipment that you can build tonight, and listen to Hale-Bopp on tomorrow! If you hear anything, send me your reports and I'll post them on my web site, The Martian Archives. If you have Internet access (and you should!), you can keep an eye on this site to see what others are hearing. The URL is: http://www.infocom.com/~thomil/

Afterword

Okay, so you built the Cosmic Crystal Set, and Hale-Bopp came and went with nary a sign of Extraterrestrial Biological Entities. Now what?

Well, you might as well keep listening. After all, there are countless microwave signals of all types within reach of the amateur, and no doubt

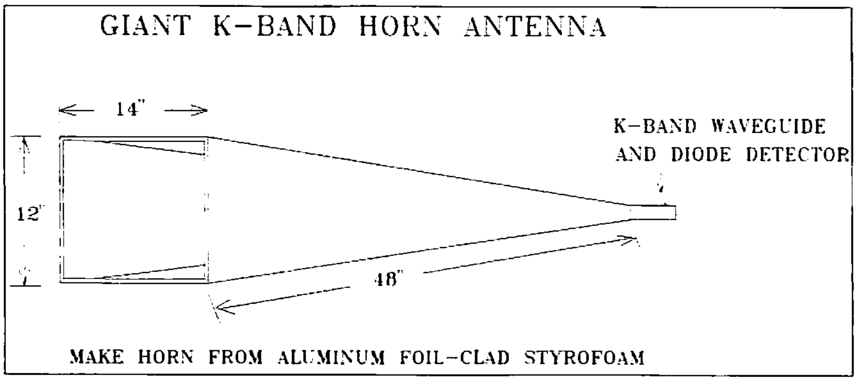

***Fig. 8.** The giant pyramidal horn is more bulky than a parabolic reflector, but is far less critical and easier to build.*

certain people wouldn't enjoy knowing that you are listening to them. What better reason is there for listening? Also, you now have a very sensitive field strength meter—connect a diode across a two-meter dipole and it should make a good sniffer for transmitter hunts. Or, you could connect the coil of an old relay to the input, making a very sensitive magnetic field monitor.

And if the E.T.s didn't send you their greetings *this* time, who knows what will show up tomorrow?

I welcome your comments... send E-mail to thomil@infocom.com. Should you prefer to correspond via disgruntled government employees, please include an SASE.

TV/VCR Tuner Applications

The first of a three-part series.

Hugh Wells W6WTU
1411 18th Street
Manhattan Beach CA 90266-4025

With the increased availability of used TV/VCR tuners, electronic projects abound for the ham experimenter. Numerous receiver and test equipment projects can be developed around TV/VCR tuners, which are the RF front ends of TV receivers and VCRs. Modern tuners are electronically tuned, which makes them mechanically stable and relatively easy to use. "Cable ready" tuners have a typical frequency range from about 45 to 900 MHz, which covers most of the desired VHF and UHF spectrum.

A list of projects supported by TV/VCR tuners could be quite extensive. A few of them are: wideband frequency converter; wideband receiver; wideband signal generator; sweep generator; standard deviation signal source; spectrum analyzer; and tracking generator. Here's a little more insight into each project.

Wideband frequency converter and receiver

These two projects are closely related in that the tuner performs the same function for each, but a different receiver is used after the tuner. Not all tuners are alike, nor do they cover exactly the same band of frequencies, but they do provide the capability of receiving a band of frequencies ranging from about 45 to 900 MHz. This band of frequencies is the typical frequency range covered by TV channels 2 through 83. Although the upper three channels have been transferred to cellular phone and other business applications, some tuners may still approach 900 MHz. There will be little loss in tuner desirability due to the band change, however.

> ***"If you don't plan to save your tuners for your projects, give them to me—I'll find a use for them!"***

The basic difference between the converter and receiver applications deals with the receiver used following the tuner. A converter is a stand-alone box which outputs a single frequency (47-63 MHz) to a receiver where the rest of the receiver functions are supported. The 47-63 MHz output is referred to as the intermediate frequency (IF) of the tuner. The tuner and receiver functions are contained within one box to provide a complete wideband receiver.

Signal generator

Within every TV/VCR tuner is a local oscillator which is intended to mix with a received signal to produce an IF. The oscillator operates typically on the high side of the received signal and is offset in frequency by the value of the IF. Normally, the oscillator signal can be accessed and used as a signal source with the support of tuning control and power. Thus a signal generator is born capable of covering the band from 90 to 915 MHz.

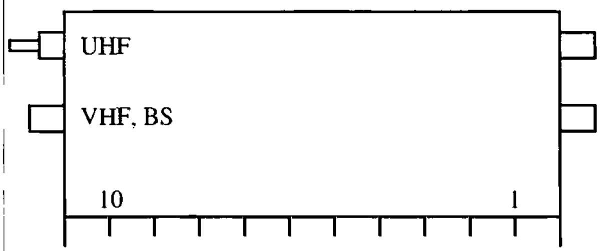
Sweep generator

A sweep generator is used to sweep a frequency across a resonant device or circuit with the objective of observing the profile of the circuit's response as a function of frequency.

With the oscillator in a tuner being used as a signal generator, a sawtooth voltage waveform is applied to the tuning voltage line, causing the oscillator to sweep across a band of frequencies. The frequency spread is controlled by the amplitude of the sawtooth, while the sweep rate is controlled by the repetition frequency of the sawtooth.

Standard deviation signal source

When a signal is frequency modulated with a sine wave audio signal, the produced carrier from the generator will



PIN	FUNCTION
1	IF
2	PLL +5 V
3	BM +12 V MIXER
4	N/C
5	BH VHF HIGH
6	BL VHF LOW
7	AGC 0-7 V
8	BS SUPER BAND
9	VT TUNING VOLTAGE 0-29 V
10	BU UHF BAND

Fig.1. Typical connector configuration.

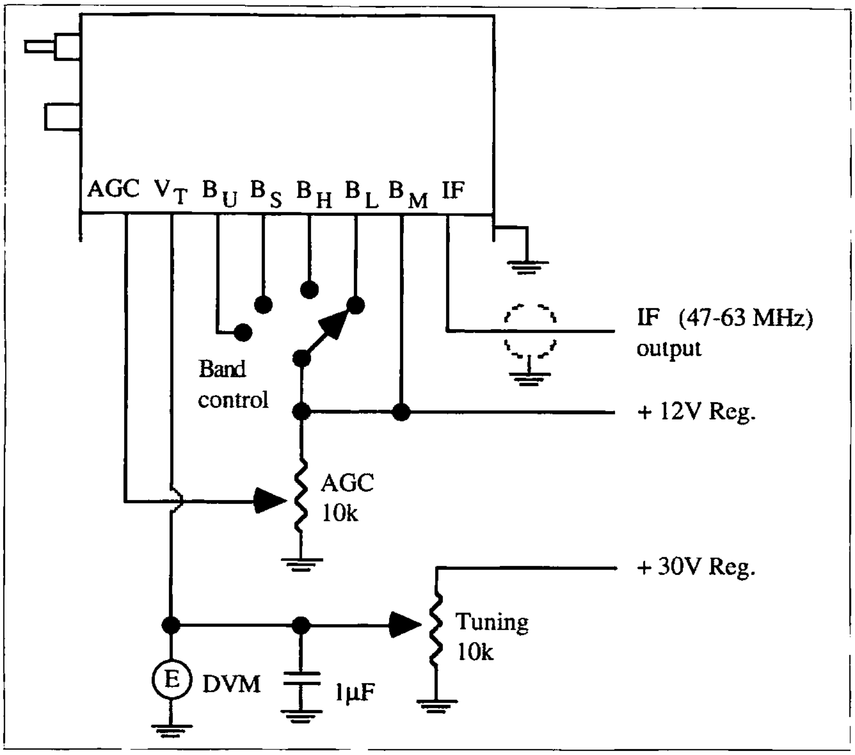


Fig. 2. Test circuit.

null in exact correlation with the amount of frequency deviation. The audio signal as modulation is applied to the tuning voltage line FMing the carrier. The amount of deviation is controlled by the amplitude of the sine wave modulation. With the use of a Bessel Function chart or a carrier null equation, the carrier null can be predicted for accurate frequency deviation measurements or as a standard deviated signal source.

Spectrum analyzer

A spectrum analyzer utilizes the sweep function of the sweep generator, but functions as a receiver. The output of the spectrum analyzer is displayed on an oscilloscope. Adjusting the sweep width allows viewing of a selected portion of frequency spectrum. One of the many uses of the spectrum analyzer is to allow the examination for purity of a transmitted signal. If the transmitted signal is "dirty," numerous spurious signals will be observed within the transmitted spectrum and centered on the signal.

VT	BL	BH	BS	BU
0	45	82	156	406
5	71	139	214	539
10	92	160	269	646
15	106	180	320	762
20	114	200	357	850
25	118	205	370	899
28	119	207	376	915

Table 1. Typical frequencies vs. voltage table.

Tracking generator

A tracking generator utilizes the sweep generator function and is used in conjunction with the spectrum analyzer to profile the frequency response of a resonant circuit. In operation, the tracking generator operates precisely on the received center frequency of the spectrum analyzer and remains in sync as it is swept across any selected portion of spectrum.

ID your tuner

Building a receiver is generally a pretty complex project, but with TV/VCR tuners available from junked equipment, the complexity is cut to less than half—making the building of a receiver feasible. Let me make you a

proposition: If you don't plan to save your tuners for *your* projects, please give them to me so that I can find a use for them. I'll even test them for you, should you desire.

The electronically-tuned TV/VCR tuners cover a wide band of frequencies, typically from 45-900 MHz, broken into 3-4 tuning bands depending on whether the tuner is "cable ready." This indicates that a super band is included. If the tuner is marked, the band indications will be BL (low VHF), BH (high VHF), BS (super band), and BU (UHF). Within the 45-900 MHz range are four ham bands, aircraft (both civilian and military), public service, hospitals, weather, taxicabs, phone systems, all TV channels, and many others.

To salvage a tuner from its resident equipment, you should observe and transfer any pin markings on the PC board to the tuner to make pin identification easier. But even without available markings, it is reasonably easy to identify the function of each pin. The specific difference between a TV and VCR tuner is the output (IF) frequency. For VCRs, the output is 63 MHz; for TV tuners, the output is 47 MHz. But even with the frequency difference, the tuners can be used alternately if need be. The supporting circuit design remains the same regardless of the IF used by the tuner.

It is best to test the tuner on the workbench prior to building it into a project. The more you know about the tuner, the easier it is to develop the supporting circuitry. All electronically-tuned tuners have pretty much the same voltage requirements, which are as follows: mixer/oscillator, 12V; tuning, 0-28V; AGC, 0-7V; band selection, 0V off and 12V enable; PLL, 5V; and AFT, ±1V.

During the visual examination the various connectors need to be identified. For a VHF/UHF tuner, there will be two antenna connectors. The UHF connector will be two parallel pins and the VHF/super band will be a phono connector. Both antenna connectors will be on the same end of the tuner. On the opposite end of the tuner, one or two more phono connectors may be present. These are arranged close to the local oscillator and provide I/O access between the oscillator and the PLL circuit.

The multiple connector pins along one edge of the tuner provide access to the various tuner control circuits as shown in **Fig. 1**. It must be clearly understood that the pin configuration will be unique for each available tuner. Starting from the oscillator end of the tuner, the pins are typically as follows: IF output; PLL; mixer/oscillator; blank pin; band control; band control; AGC; band control; tuning voltage; and band control. Some tuners have an AFT terminal which is normally used for fine tuning.

Testing a tuner is straightforward in nature, but does require a receiver covering the tuner IF; two regulated power supplies; two 10k pots; a DVM; a VHF and/or UHF antenna; and a couple of short-length clip leads having small-size clips. For UHF, two wires, each about three feet long, can form a rabbit-ear-style antenna; a 146 MHz antenna will work well for VHF.

Fig. 2 shows a typical circuit for testing a tuner. The procedure for tuner setup is as follows: Set the receiver to 47 MHz (or 63 if a VCR tuner is used). Connect the antennas to their respective connectors. Set one power supply to +12V and connect the voltage directly to the mixer/oscillator pin. The negative voltage side connects to the tuner case. Connect one 10k pot across the 12V supply and adjust the output to 5-6 volts. Connect the wiper to the AGC pin. Connect the second pot across the second power supply and set the supply to +30V output. Adjust the pot (tuning voltage control) to 0V. Connect the pot wiper and a DVM to the tuning voltage pin. Connect a clip lead from the +12V output and temporarily attach it to one of the band control pins. During testing, the AFT terminal, if present, may be grounded.

Open the receiver squelch and very slowly adjust the tuning voltage from 0V to maximum, and back again. If you hear a station, stop to record the tuning voltage value and the band control pin number. If the station can be identified by a service, then it should also be noted. Critically adjust the AGC voltage for maximum sensitivity upon hearing the first station. Measure and record the AGC voltage and leave it set for all remaining tests. Repeat the tuning procedure for each band control pin.

Table 2. Frequency spectrum.

When checking the bands, use the chart shown in **Table 1** as a guide. For the UHF band, the only signals heard on the top of the band will be cell phone, and the tuning voltage will be in the range of 20-28 volts.

From the band control and tuning voltage information, a tuning voltage vs. frequency chart can be developed in a manner similar to that shown in **Table 1**. After the tuner has been tested and the voltage requirements noted, select and build a project around the tuner. Tune the spectrum as shown in **Table 2**. Again, if you aren't going to use the tuner, give it to me.

Next time: frequency converter, mobile power.

Build a Colloidal Silver Generator

Do-it-yourselfing has always been the heart of hamdom.

Thomas M. Miller WA8YKN
314 South 9th Street
Richmond IN 47374
E-mail: thomil@infocom.com

The discovery of antibiotics is often considered the most important breakthrough in modern medicine. Beginning with the introduction of penicillin in the early 1940s, one disease after another fell to the constant onslaught of new and more powerful drugs. Armed with this powerful new arsenal, many doctors believed that the end of all infectious disease was within their grasp.

Bacteria, however, are difficult to conquer. The oldest life form on the planet, they have survived, and thrive, virtually everywhere on Earth precisely because they are adaptive—capable of changing themselves in response to a hostile environment.

When bacteria are constantly exposed to antibiotics, they will do what they do best—adapt. If only a single bacterium manages to survive an antibiotic attack, that organism can produce over 16 *million* offspring within 24 hours, and each of these will inherit the ability to resist that drug.

In the late 1970s, new strains of disease-causing organisms began to emerge that were resistant to antibiotic drugs. Researchers have tried to counter by developing new and even more powerful drugs, but it appears to be a losing battle. More and more bacteria are becoming MDR (Multi-Drug Resistant), and new drugs are becoming more difficult and expensive to produce. And, while a new drug may take a decade to reach the pharmacy shelf, bacteria can mutate in hours.

"Unlike antibiotic drugs, the use of silver does not produce resistant strains of bacteria."

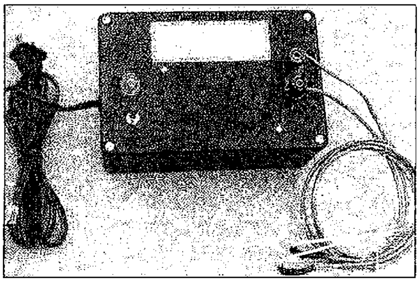

Photo A. *The Colloidal Silver Generator, with pure silver electrodes. Pure silver colloid, a natural antibiotic, can be made for the cost of distilled water!*

Don't despair!

Fortunately, alternatives to antibiotic drugs do exist, and the most promising is silver. Commonly used prior to 1938, silver is a natural broad-spectrum antibiotic. In fact, while most antibiotic drugs are effective against a select few types of bacteria, silver is known to kill over 650 different disease-causing bacteria, and many viruses as well—yet silver is completely non-toxic. Unlike antibiotic drugs, the use of silver does *not* produce resistant strains of bacteria.

Like other metals, pure silver is generally found in the crystalline state. The body, however, cannot utilize crystalline metals; they must first be transformed into the *colloidal* state. A colloid consists of extremely tiny particles of a substance, suspended (not dissolved) in pure water. Each particle contains only about 15 atoms, and is hundreds of times smaller than a red blood cell. Colloidal silver can be easily absorbed and utilized by the body to fight bacterial and viral infections. Some doctors believe that silver is necessary for proper operation of the immune system.

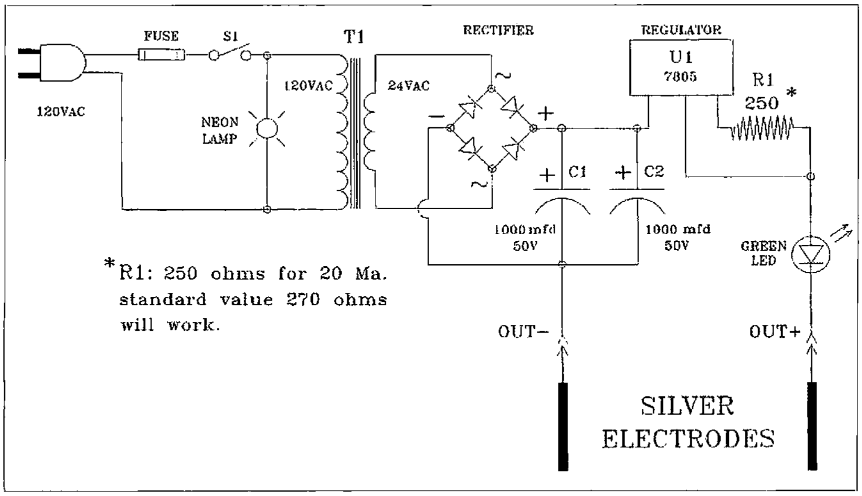

Fig. 1. *Schematic diagram of the Colloidal Silver Generator. Regulator U1 provides a constant 20 milliamps to the pure silver electrodes. The green LED indicates current flow.*

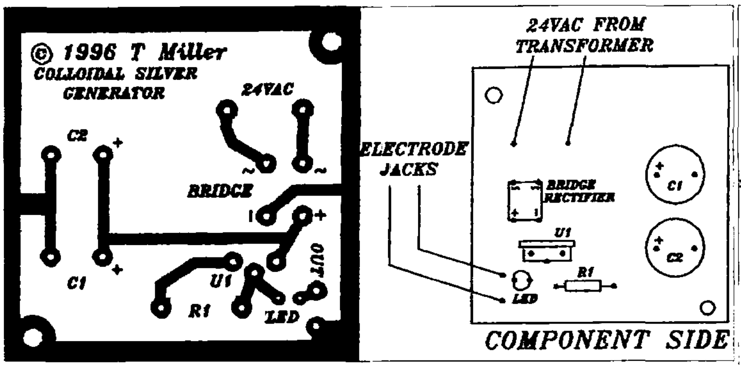

Fig. 2. Printed circuit board pattern (foil side) and component layout. Boards are available from FAR Circuits.

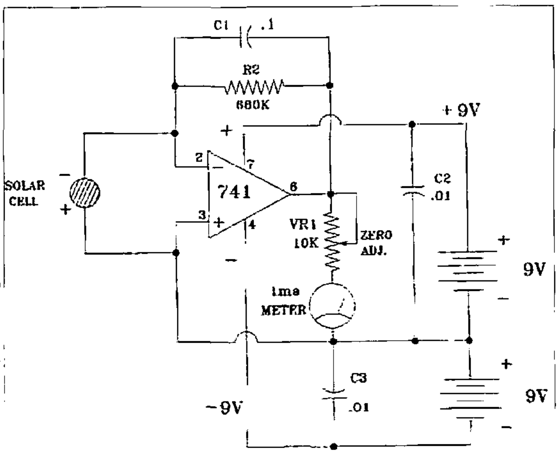

Fig. 4. Schematic diagram of the light meter used to check silver concentration. The circuit measures scattered laser light.

Before 1938, colloidal silver was manufactured by a mechanical method: the silver was actually crushed and ground to fine particles. Unfortunately, it is nearly impossible to grind a substance to the size of atoms, so this method produced a very poor-quality colloid. Today, colloidal silver is produced by an electric process that results in extremely fine particles. Since these particles carry an electric charge, they repel one another and remain suspended in an electric field. This helps prevent the silver particles from settling to the bottom.

It couldn't be easier...

A daily tablespoon of colloidal silver can be taken orally, either alone or mixed with water or juice. It can be absorbed directly by simply holding a small amount in the mouth for a minute or two. It also promotes healing and prevents infection when used externally on cuts, scrapes and rashes. Colloidal silver can be sprayed on kitchen countertops, added to laundry and bath water, used to sterilize canning jars and lids, and even added to your pet's water dish to prevent bacterial growth.

The one drawback to this amazing substance is the cost. Colloidal silver is available in most health food stores as well as by mail, but the average cost is between $5 and $10 per ounce! This high cost prohibits most of the applications we've mentioned, since it would cost $100 to fill an average spray bottle. Also, tests have shown that the quality and purity of the colloidal silver on the market varies widely, and it's hard to tell exactly what you're getting.

The answer to these problems is to do what hams do best—make it yourself! The circuit required to generate a silver colloid is simple, and once built, will make hundreds of gallons for virtually the cost of the water.

"...Silver colloid solution may be the most useful health enhancement tool in your environment." — Bob Beck

A few months ago, a reader sent me a paper written by Physicist Bob Beck. In this paper, Dr. Beck described his circuit for making colloidal silver, which consisted of three 9-volt batteries connected to provide 27 volts, a 28-volt 40-milliamp light bulb, and two electrodes made of pure silver wire. The light bulb, wired in series with one electrode, acted as a ballast resistor to limit the current. Since distilled water does not conduct electricity very well, a tiny amount of pure salt is added until the bulb produces a "dim glow." Five minutes of this will, according to Dr. Beck, produce a high-quality colloidal silver concentration of 5 to 7 ppm (parts per million).

I built Dr. Beck's circuit, and it did indeed produce colloidal silver. The only drawback I found was that the "dim glow" of the bulb was a somewhat subjective indication of current, which varied with the conductivity of the water, the condition of the batteries and the length of electrodes immersed in the water. This made it difficult to get repeatable results. What was needed was a circuit with fewer variables.

With this in mind, I designed the circuit shown in **Fig. 1**. The circuit uses a small 24-volt transformer, a bridge rectifier, and two electrolytic capacitors to form a small AC-operated power supply. This supply provides 32 to 35 volts DC to a 7805 regulator, which is connected as a constant-current source. Since Dr. Beck's current indicator was a 40-milliamp bulb lit to half-brilliance, I selected the resistor R1 to provide 20 milliamps, allowing the use of a standard Light-Emitting Diode (LED) as an indication of proper operation.

This is a very simple and non-critical circuit, and could easily be wired point-to-point on a small piece of perfboard. However, to make the circuit as easy to build as possible, a circuit board pattern and parts layout is shown in **Fig. 2**. I mounted the completed circuit in a small

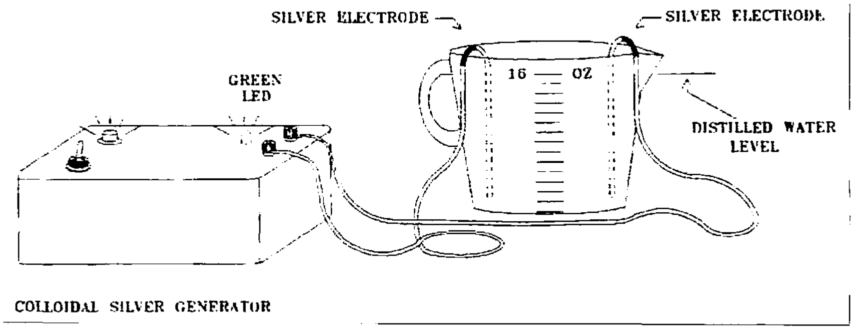

Fig. 3. Making silver colloid is easy: use a glass measuring cup and 16 ounces of distilled water. Let the generator run for 5 to 7 minutes.

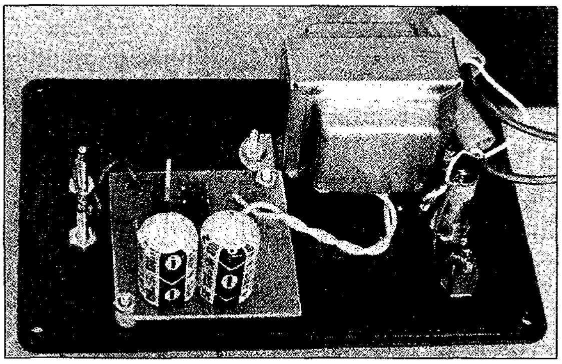

Photo B. Inside the colloidal silver generator. The LED is mounted on the back of the circuit board and extends through the front panel.

plastic project box with the AC switch and pilot lamp on the left side of the panel. I put the LED and a pair of binder posts to connect the electrodes on the right. The completed Colloidal Silver Generator is shown in **Photo A**.

The most critical component of this project is the electrodes. They **MUST** be made of .999 fine silver. **DO NOT** under any circumstances use "sterling" or any other silver alloy, as the metals used can be toxic in even very small amounts.

Cut two pieces of #12 round fine silver wire, each 4 inches long. Solder a 24-inch piece of flexible insulated hookup wire to one end of each electrode. Clean each solder joint with flux solvent and coat the solder with a drop of clear urethane varnish or nail polish. Slip a 1-inch long piece of shrink tubing over each wire and push it down to cover the solder joint. Use a heat gun to shrink the tubing over the connection.

Using needle-nose pliers, bend the upper portion of each electrode, just below the solder joint, in a "U" shape about one-half-inch wide. When the electrodes are hooked over the side of the glass, about three inches of silver wire should extend down into the water. Note that the shrink tubing and solder joint **MUST NOT** be submerged! You do not, after all, want to make "colloidal lead" or "colloidal tin." Strip the ends of the electrode cables and connect them to the Colloidal Silver Generator.

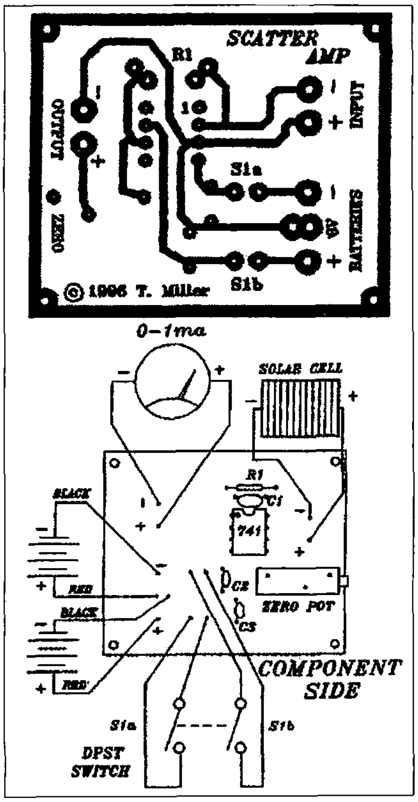

Fig. 5. Circuit board pattern (foil side) and parts layout for the light meter. The solar cell is very fragile, so handle with care.

"Every mineral that exists is dissolved in the sea, and therefore is also present in sea salt."

You will need some distilled water and also some non-iodized salt. Don't use iodized salt, as the iodine could make unwanted chemical compounds. Also, some brands of salt use aluminum silicate as a desiccant, and while it's not likely that this could be harmful in such tiny amounts, I checked the labels until I found one that uses sodium silicate instead of aluminum.

Some people have suggested using "sea salt" as an alternative to table salt. Sea salt is the residue left behind when seawater is evaporated away. Not only iodine, but *every mineral that exists* is dissolved in the sea, and therefore is also present in sea salt. In fact, sea salt is sometimes used in place of table salt as a trace-mineral supplement. Use only pure, plain, non-iodized salt.

Colloidal silver should be made and stored in a glass container. Plastic can hold a static electric charge which will cause the silver particles to collect on the sides. I use a 16-ounce glass measuring

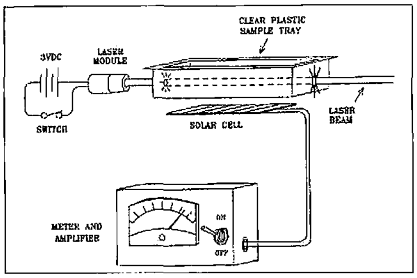

Fig. 6. Method for checking silver concentration. The solar cell comes packaged in a plastic "bubble pack" which makes a perfect sample tray.

cup. Hook an electrode over each side of the rim, and fill the cup with distilled water. The electrodes should extend down into the water, but remember that the solder joint must be above the water line. The proper setup is shown in **Fig. 3**.

When you first turn on the Colloidal Silver Generator, the pilot lamp will glow. The green LED may glow very faintly, or not at all, depending on the conductivity of the water. Add a tiny amount of salt, just a few grains at a time, and stir gently with a plastic spoon. Add just enough to make the green LED glow to normal brightness. If you look closely at the positive electrode, you will see a wispy cloud of silver particles coming off into the water like faint white smoke. After five minutes, turn off the Colloidal Silver Generator, remove the electrodes from the cup, and gently stir the colloidal silver with a plastic spoon. Silver is sensitive to light, so keep the colloidal silver in a dark brown glass bottle and store it in a cool, dark place. Always shake the bottle before using your colloidal silver.

After each use, the electrodes must be polished slightly to remove the oxide and scale. Use a small piece of fine synthetic scouring pad, such as Scotch-Brite™, and gently polish them until they are clean. Avoid over-polishing, since you don't want to wear away the silver.

Testing the concentration

After making a bottle of colloidal silver, I realized that I had no way to determine exactly how much silver was in suspension. Colloids are

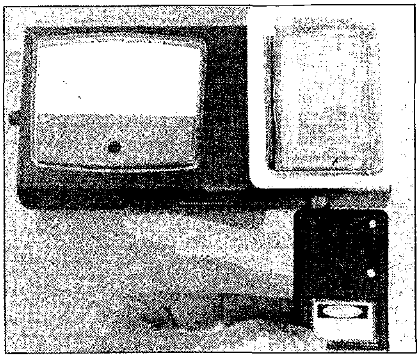

***Photo C.** Since the radius of the silver ion is less than 2 angstroms, far too small to see, silver concentration is checked with a diode laser and a light meter to measure the scattered light. Five to ten parts per million (PPM) is ideal.*

measured in parts per million (ppm), and the concentration of most commercial colloidal silver is in the 5 to 10 ppm range. With a constant current regulator and a measured amount of distilled water, the only remaining variable is time: How long does it take to make a 5 ppm concentration of colloidal silver?

Dr. Beck's article recommended using a small laser pointer to check the silver concentration. These pointers use a laser diode to produce a visible red beam. I ordered a laser diode module and mounted it, along with two 1.5 volt "N" cells and a switch, in a small plastic box.

The laser beam, shining through a sample of distilled water, is invisible when viewed from the side. However, when the laser is directed through colloidal silver, it makes a softly glowing red beam due to the tiny silver particles scattering the light. The intensity of the glow is proportional to the concentration of silver—the more particles there are in suspension, the more photons will be scattered. Simply looking at the glow, however, does not give an accurate measurement. I needed a way to actually measure the scattered light.

RadioShack™ sells a small silicon solar cell (part number 276-124). I bought one of these cells, and *carefully* cut the plastic bubble-pack from the solar cell package—the clear plastic bubble is just the right size to make a small transparent sample tray. I built a small amplifier to drive a meter and attached it to the solar cell. By placing the clear plastic sample tray on top of the solar cell and directing the laser beam through the sample, I could directly measure the scattered light. Of course, the solar cell was also sensitive to normal room light, so my first experiments were done in the dark. I set up the sample and shut off the lights before turning on the amplifier. Later, I made a small cardboard box which I could place over the sample under test.

I first tested a sample of colloidal silver and adjusted the meter zero pot until the meter read full scale. Then I mixed a sample diluted 50% with distilled water—the meter read half scale! A sample of distilled water read nearly zero, with only a tiny amount of reflected light caused by the sides of the sample tray.

This method worked, but it provided only a relative reading. To calibrate it, I filled the sample tray with a commercial 5 ppm colloidal silver purchased at a local health food store. I adjusted the meter zero to read "5" on a 0 -15 scale, then tested a sample which I had made by running the Colloidal Silver Generator for exactly 10 minutes. This sample registered nearly "10" on the meter; double the concentration of the commercial product.

It was clear to me that running the Colloidal Silver Generator in 16 ounces of water for five to seven minutes will produce an ideal concentration of silver. Therefore, if your only interest is in making your own colloid, it's not necessary to build the light meter. I have included the circuit here for those who wish to experiment with the laser backscatter phenomenon.

Fig. 4 shows the schematic diagram of the meter amplifier, while the circuit board pattern and layout is shown in **Fig. 5**. There is nothing critical about the circuit, but note that the solar cell is *extremely* fragile, and you must carefully solder wire leads to each side. Use only small, flexible wire to avoid placing any stress on the solar cell. I used a piece of tiny two-conductor wire from an old earphone. **Fig. 6** shows the method used to measure the laser backscatter.

I would enjoy hearing from readers about their experiences with colloidal silver. The easiest way is via the Internet: My E-mail address is thomil@infocom.com. Also, information on this and many other circuits is available on my Web page. If you have access to the Web, the URL is: http://www.infocom.com/~thomil/.

Letters sent via the U.S. Postal Service will also (eventually) reach me. If you write, please include an SASE.

Cable X-Perts' G5RV Multiband Antenna Kit

What to do when you're tired of making do.

Peter A. Bergman NØBLX
3517 Estate Dr. SW
Brainerd MN 56401

After several years of using dipoles strung from trees and whatever, I decided to get more organized and try something different. House wire and lamp cord just weren't doing the job for me.

I thought about just getting some hard-drawn wire and using it to replace my dipoles, but I had worked a number of stations that were using G5RVs and decided to give that a try.

While the G5RV looks like an open-line-fed dipole, it differs in a couple of ways. A conventional dipole is cut to a half-wavelength on the lowest frequency of interest. However, a full-size G5RV is cut to 3/2 waves at 14.15 MHz (102 feet) and uses 34 feet of open line as a matching section. This provides a pretty close match to feedlines with impedances of anything from 50 to 80 ohms, either twinlead or coaxial cable. Since the whole system will be brought to resonance with a tuner anyway, the standing waves on the feedline won't matter too much.

While the 34 feet of ladderline functions as a matching transformer on 20 meters, on the rest of the bands it functions as a "make-up" section to accommodate that portion of the standing wave (voltage and current components) which cannot be handled on the flattop.

Since there are no ferrite beads or traps involved, the G5RV tends to be very efficient. On 80 meters the pattern looks like a typical dipole. On 40 and 30 the pattern is similar to that of two half-waves fed in phase. On 14, 18, 21, 24 and 28 MHz the pattern is that of a long-wire antenna.

The full-sized G5RV can also be used on the 160-meter band by shorting the feedline and bringing the antenna to resonance with a series-connected capacitive-inductive tuner. The tuner, of course, must be connected to a good earth ground or counterpoise wire.

If space is limited, the flattop and matching section can both be shortened by half, which will produce an efficient antenna for seven through 28 MHz. If you want to use the half G5RV on 160 and 80 meters, the above tuner and shorting arrangement will have to be made. In this case the G5RV will perform more like a top-loaded vertical but should still provide good performance.

Since it probably won't be practical to connect the transmitter directly to the matching section, some kind of feedline will be necessary. According to what I've read, almost any line—coax or parallel—with an impedance of 50 to 80 ohms will work. Try to keep the feedline under 70 feet in length. The use of a balun is not recommended.

After thinking about it for a while and checking the junk box—where I found mostly junk—I decided to order the G5RV kit from Cable X-Perts.

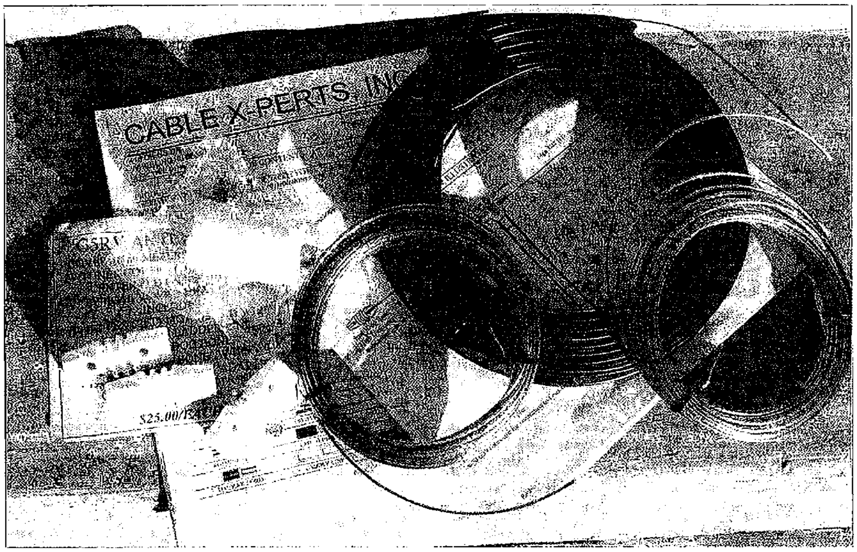

***Photo A.** Cable X-Perts' G5RV multiband antenna kit.*

This is a *kit*?

The hefty box arrived in a very few days, which was gratifying. The contents (**Photo A**) included 104 feet of 14-gauge 7/22 hard-drawn copper wire, 35 feet of 450-ohm ladderline, two end insulators, a center insulator and a 450-ohm ladderline-to-coax adapter. Also included was a detailed set of instructions and a reprint of an article by Louis Varney G5RV himself. The article explains the theory of operation of the antenna and adds some detail on the proper installation.

Calling this a kit is a bit of a stretch, since the whole assembly job can be done on the kitchen table in just a few minutes. There are only four solder connections to make, but you will definitely want to use a gun for this job. Especially

on jobs where a lot of material is involved, I prefer to do my soldering indoors or at least out of the wind. It can be difficult enough to get a joint hot enough for the solder to flow properly when you have 85 feet of copper wire sucking heat away without having the wind cooling it, too. I have even been known to drag the end of an antenna into the car just to get out of the wind.

Installing the antenna should be pretty straightforward. Make sure you unroll the wire and the ladderline. Don't just pull it off the roll sideways like line coming off a spinning reel. If you unroll it there will be less risk of getting kinks in it and the wire should hang straighter.

The G5RV can be installed as an inverted vee, but the angle is supposed to exceed 120 degrees. It's best to think of it as a flattop. The ladderline should hang in the clear as much as possible, and at least the top twenty feet of it should hang vertically. Naturally, it's best if the antenna is mounted high enough that the entire matching section is vertical and the connection to the feedline is suspended above the snow (in my case it requires a center support about 40 feet high—so much for global warming).

How does it work?

Some users who have been able to hang the antenna above 35 feet with the matching section in the clear have reported VSWRs of two or less throughout most of the HF ham bands. My situation is not nearly so ideal, but it requires very little tweaking with the tuner to achieve unity SWR anyplace I want it.

I sometimes work QRP and never use more than 80 or 90 watts; as far as efficiency is concerned, the G5RV is a vast improvement over what I'd been using. I am getting closer to the ideal of "hear them and work them."

Whether you're an old hand at all this, or a newcomer looking for your first HF antenna, give the G5RV some consideration. Or, if you have some other antenna design in mind and are looking for quality materials, take a look at the Cable X-Perts catalog. I think you'll be pleased. For further information, contact Cable X-Perts, 416 Diens Dr., Wheeling IL 60090; to order ($25 plus $6.50 s&h) call (800) 828-3340; for technical information call (847) 520-3003; FAX (847) 520-3444.

An 8088 Clock Upgrade

Recycle!

Lisa Davis
2830 W. Kent Drive
Chandler AZ 85224

Evert Fruitman W7RXV
2808 West Rancho Drive
Phoenix AZ 85017-2646

You would probably be hard pressed to find a man-made computer older than the abacus. The masters of this somewhat primitive machine could do calculations with great dexterity and surprising speed. Today, you are more likely to find one in a curio shop than in a business or a scientific laboratory.

Once the early computer developers got past the beads and wires of the abacus, they tried many different things for the switching and the storage elements. Relays, vacuum tubes, and transistors all served the purpose. Eventually, engineers combined many transistors into one package, making the now common integrated circuit. This gave a saving in space, a notable increase in speed and a monumental increase in complexity.

At first, those who had to do many complex computations found the accuracy of these mechanical computers somewhat of a delight. But when programmers found that the machine could do calculations much faster than people, as well as more accurately (most of the time), speed soon became the primary goal.

Just a short time ago, a dual-speed 4/6 MHz system was considered state of the art.

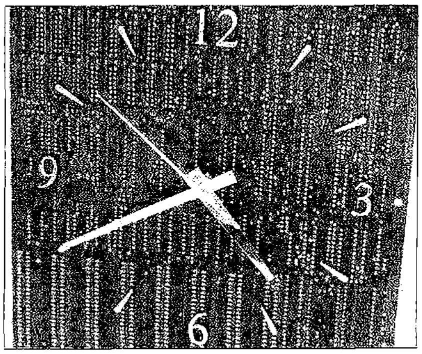

Photo A. *Front view of the 8088 clock.*

Now a system that runs slower than 100 MHz seems outdated. As the 8088 gave way to the faster 80286, and the '286 gave way to the '386 to the '486 and finally (for now, that is) the Pentium™, the older processor boards found their way to the scrap heap more and more frequently. Here is a modification for one of those old boards that could put it back on your desktop, or even on your wall.

The modification

As the photo shows, this modification uses an external clock. However, do not panic—you can find this critical component at a hobby/craft store. Although the original plans call for an 8088 motherboard, any other board about the same size will give equally pleasing results. Simply look for a clock suited to the dimensions of your particular board. While at the store, you may want to consider the possibility of framing your finished system. It should take less than an hour to make the improvements to the 8088 board.

Start the modification by locating the center of the board. With a small electric drill and a high-speed bit, drill the mounting hole indicated in the instructions that come with the clock. Next, mount the clock, attach the hands and the numbers, then install the battery and set the clock to the correct time of day. Finally, locate a suitable spot on your desk or wall and set it in its newfound place of honor. This simple, relatively inexpensive modification gets some of those old boards out of the scrap pile by making an upgraded 8088 board into a system suitable for use on your desk or wall. In our case, the clock made a nice gift for someone who works with computer hardware and software all day and found the clock a delightful addition to his office wall.

The California Phased Array

Easy to build, easy to use—and even easier on the billfold!

Dave Evison W7DE
153 Park Avenue
Palo Alto CA 94306

If you're interested in a compact, small-footprint wire antenna for 20 meters that has an honest 3 dB gain, is electronically rotatable, requires no tuner, and can be built for less than $25, read on—because that describes the California Phased Array.

The design constraints for the original California Phased Array were my very thin billfold, small city lot, TenTec Scout (50W), and a couple of palm trees. Since the palm trees are about 50 feet tall and spaced about 40 feet apart, I figured I had a couple of environmentally-correct towers. The immediate response was to simply stretch a dipole between my "organic supports." This I did, and though it worked admirably, I pined for something with gain and directivity. The technical requirements began to form in my mind: No radials, feedpoint at least 1/4 wave off the ground, and gain of 3 dB. From these points, the California Phased Array was conjured.

Say "abracadabra"

The antenna is actually a pair of half-wave wire dipoles, vertically oriented, and fed in phase or 180° out of phase—hence a two-element broadside or endfire array (and a "California" Phased Array because of the palm trees). Using half-wave dipoles eliminated the need for a radial system, ensured the smallest possible footprint, and elevated the feedpoints greater than 1/4 wave above earth ground (see **Fig. 1**).

The dimensions for the dipoles and phasing lines were calculated from the standard antenna formulas at 14.2 MHz, and they are specified in **Fig. 2**. Although the original California Phased

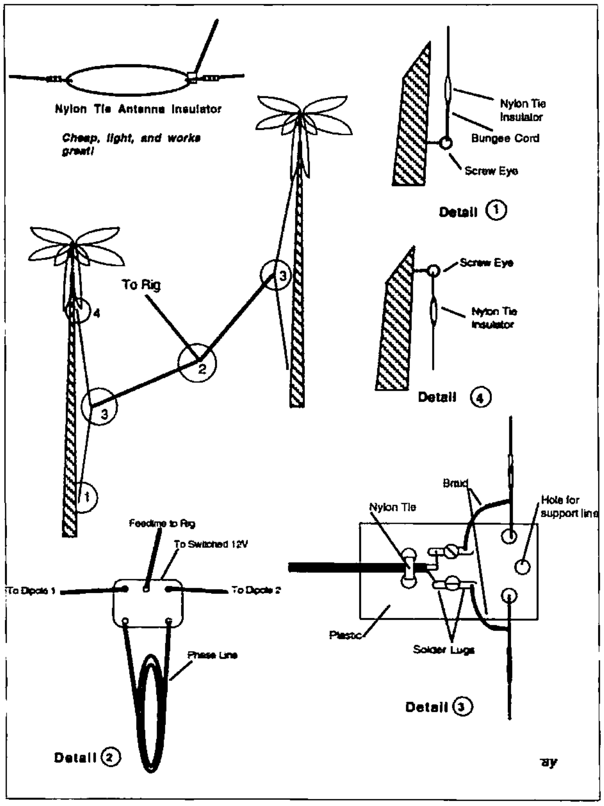

Fig. 1. See why it's a "California" phased array?

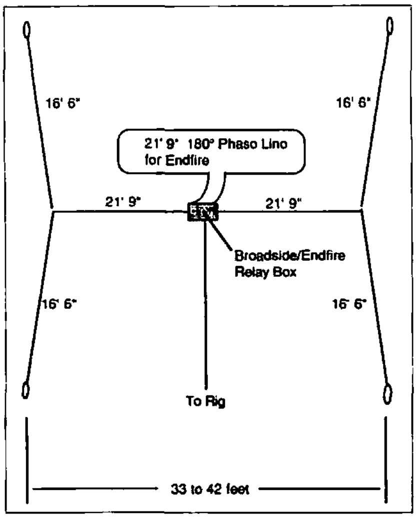

Fig. 2. Dimensions of W7DE's setup.

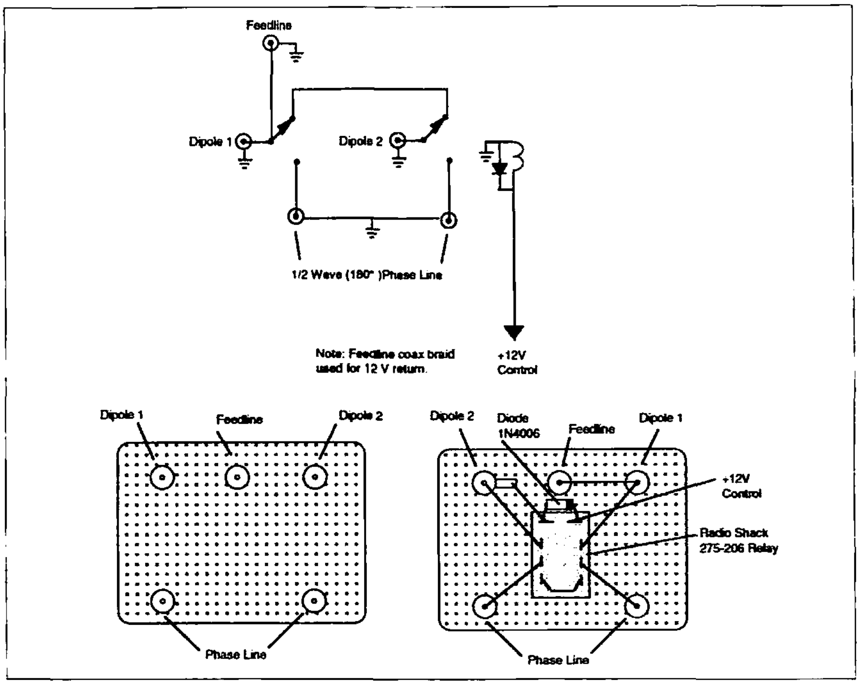

Fig. 4. Remote control box for electronic rotation.

Array was designed around the palm trees as supports, and the dipoles are separated by approximately 40 feet, other available supports and spacings can be utilized (H-plane patterns for the California Phased Array, depending upon your final spacing, can be found in *The ARRL Antenna Book*). Some alternate physical configurations are illustrated in **Fig. 3**.

Details for the relay assembly that switches the additional half-wave phasing line in and out (to rotate the array electronically) are shown in **Fig. 4**. The relay and BNC connectors were assembled in a small metal enclosure. The shield of the coax feedline is used for the DC return when energizing the relay coil.

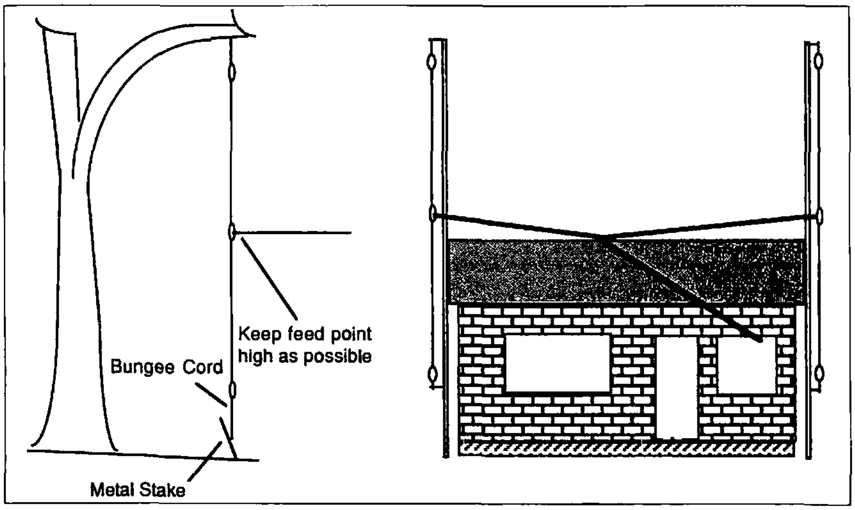

Fig. 3. Alternate configurations.

The initial checkout of the antenna was performed on the broadside configuration. I measured each dipole individually and found it to be flat across the band and about 47 ohms. When I connected the phasing lines of the antennas together, I fully expected to see something around a 2:1 SWR (about 23 ohms); instead, I found virtually no SWR and 47 ohms across the entire 20-meter band. I even changed the battery in the little MFJ SWR analyzer, and still got the same measurements. Here's why: If an array of two identical elements is fed in phase or 180° out of phase, both elements have the same feedpoint impedance. With these arrays, feeding the elements through equal lengths of feedline (in phase) or lengths differing by 180°

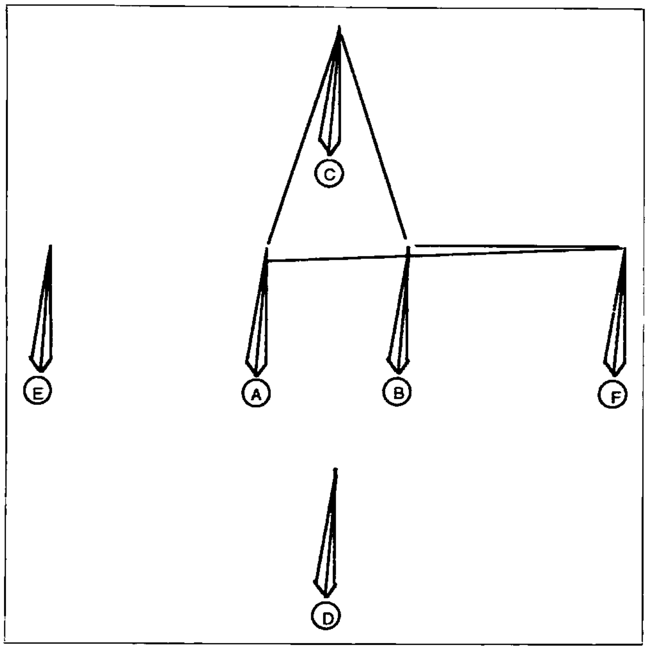

Fig. 5. Gain and directivity.

the signal from one transmitting antenna is farther away by one half-wavelength and it will arrive at the receiving antenna 180° later than the closer one. This will put the signals back in phase and the signals will add.

(out of phase) will lead to the correct current and phase match, regardless of the what the line length is.

The California Phased Array can deliver an honest 3 dB gain, and here's a simple explanation of how it does (see **Fig. 5**).

•Broadside (in phase) phasing: Antennas (A) and (B) are identical vertical dipoles separated by one half-wavelength and fed in phase. Receiving stations (C) and (D) are equally distant from antennas (A) and (B). The signals from (A) and (B) will, therefore, reach antennas (C) and (D) at the same time, in phase, and will add. However, receiving stations (E) and (F) will receive the radiated signals from antennas (A) and (B) 180° out of phase because the signal from the transmitting antenna that is farther away by one half-wavelength will arrive at the receiving antenna 180° out of phase, subtract and cancel out.

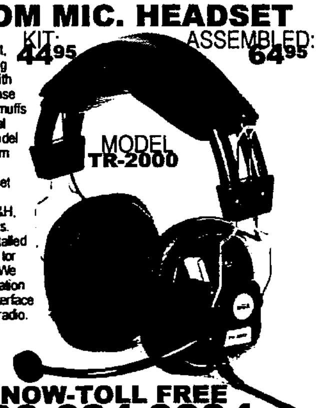
•Endfire (180° out of phase) phasing: The antennas are the same as above, but this time antennas (A) and (B) are fed 180° out of phase. In this case, since receiving stations (C) and (D) are equally distant from antennas (A) and (B), the signals will reach antennas (C) and (D) at the same time, but since the radiated signals are 180° out of phase, they will subtract and cancel out. However, in the case of receiving stations (E) and (F),

It's so simple

There you have it: Gain and directivity with a simple wire antenna system—and all you need to rotate it electronically is a simple relay to switch an additional phasing line in and out.

The only thing critical about this antenna system is to be as precise as possible when preparing the dipoles and the feedlines. If a metal tower is used for support, the proximity of the tower will affect the characteristics of the dipole and distort the radiation pattern to some degree, but who knows? It may even improve performance. The original California Phased Array used RG-58U, because it's light and I never run over 100 watts. For high power usage RG-8 must be used.

Upon completion of the antenna system, I conducted its maiden test. While running 50 watts SSB, within a 35-minute period (I did a little rag-chewing) my first contacts included W1AW (CT) and KH6/W7GMH in Hawaii. This certainly demonstrated that the two major lobes were doing what they were supposed to do in the broadside configuration. A second test (also in the broadside configuration) was performed during the California QSO Contest (5 October 1996) and within an hour and a half, I worked 12 states and Canada (once again, 50 watts SSB). On-the-air testing is still underway in the endfire configuration (which is north and south from my San Francisco-area QTH). I'm sure hearing a lot of Spanish-speaking stations, so I guess I'll have to brush up on my Spanish!



Kindergarten, a Two-Wheeler, and a Ham License

It's fun, and very handy, to have more than one amateur radio operator in the family.

Peter A. Bergman NØBLX and
Chandra E. Bergman KBØYXB
3517 Estate Dr. SW
Brainerd MN 56401

My middle daughter Chandra, a/k/a "Shorty," has been wanting to be able to talk to me on the radio since she was two years old. Around Christmas 1995, after her sixth birthday, she said that she wanted to get her radio license so she could talk on the radio. That was an entirely different matter. She had been along and helped a bit during various public service activities, so she knew there is more to ham radio than being able to talk to people while they drive around. She had also expressed an interest in HF QRP. "Work the world on a watt," she says.

For those of you who are new to all this, getting an amateur radio license does require that the applicant pass some tests. Each of the six license levels carries with it a different level of privileges. At this time the no-code Technician license seems to be the entry point of choice to ham radio.

The Federal Communications Commission sets the standards and specifies what must be covered in the various tests. Fortunately, the FCC publishes a pool of test questions and answers from which the actual tests must be compiled, so there is no doubt about what must be studied for each class of license. Study guides containing the complete pool for the desired class are available from several sources.

I told Chandra that I would have to order a special book for her to study and that she would have to study every day. Then I waited a few days and she asked again, and again a few days after that. At that point it seemed she was still serious so I ordered Artsci's *Riding the Airwaves with Alpha and Zulu*. I chose that particular study guide because about half of the book is cartoons and illustrations which I hoped would help hold a young person's interest.

At least once a day I heard, "Dad, is the special book here yet?" Fortunately, the book arrived on January 9th, less than a week after it was ordered.

Since a completion certificate is provided for those elements passed at each test session and since the certificate is good for a full year, we decided on a simple strategy. We tackled one element at a time. There are tales of people walking in off the street and walking out with General class license, but I thought that would be a bit much for a six-year-old.

Chandra did pretty well in her studies. Sometimes it was hard to "stay on task" but we managed to have a study session almost every day, usually between supper and bedtime when we would normally have story time. Sometimes we had story time, too. Despite the fact that Chandra was only in kindergarten there were many, many distractions. One day she brought home the "Teddy" bag from school. Teddy had to be clothed appropriately, fed at regular times and a log book kept so she could tell the class how Teddy's visit to our home went. Teddy joined us for our study session that night.

I asked Shorty once if she had tried telling her schoolmates about ham radio and her studies. She said that she had but, "Dad, it takes an *hour* to explain it!"

Our original target date for her first test was the Fergus Falls hamfest on April 20th. But when she heard that I was going to the Fargo (North Dakota) hamfest on March 9th, she wanted to go along so she could try the test. Fortunately we had a friend along who could be the reader (responsible adult) with her in the test room. I did not want to be there because I was too deeply involved and I had a booth at the hamfest. I was afraid that I'd get both of us

Photo A. Chandra Bergman KBØYXB, age 6, passed her Novice written test—and *learned to ride a two-wheeler.*

thrown out by prompting her. Besides, the VEs wouldn't let me.

During the test I was as nervous as a long-tailed cat in a room full of rocking chairs—but somehow I managed to keep my mind more or less on the booth.

No, she didn't make it. She got 20/30 and needed 22/30 to pass. But she came out of the experience determined to do better at Fergus Falls. Some of the things Dad had insisted she'd have to know actually showed up on the test. She got more serious at study time. Well, sort of. To help her with some of the facts she had to learn—like frequency assignments—we made little signs which we hung in various places around the house—the refrigerator door was our favorite spot.

The weeks between the Fargo hamfest on March 9th and the Fergus Falls (Minnesota) hamfest on April 20th seemed to go by awfully fast. All of a sudden it was 4:00 am, April 20th. We were on our way to Fergus Falls. I thought about going over

some of the questions while I drove in the dark. Or getting Joe NØUME, our handi-ham buddy, to drill her a bit. Chandra had other plans—she went to sleep. We arrived early enough that we were able to join some friends for breakfast.

During breakfast I did ask some questions, both of Shorty and her friend Mike, who was also testing. She seemed to have her facts straight and rattled off answers between bites of food. One of the restaurant's other patrons that morning happened to be one of the Volunteer Examiners. He came over to visit with us for a few minutes and announced that a separate room would be set up for the kids so the reader and the kids wriggling wouldn't unnerve any of the other candidates.

Shorty was cool. We arrived at the fairgrounds, got the car unloaded, got Joe out of the car and into his chair and set up the booth. Chandra displayed her usual *joie de vivre,* both helping me and running all over the place with her friends.

Sharon KBØSQX, Shorty's reader, and her husband Jim KBØTXT arrived well before test time. Chandra had never met them but took an instant liking to them and seemed very relaxed with Sharon. Finally, they went in to test and after what seemed like a long, long time, they came back out with my daughter, as always, hyperactivating all over the place. An eon later we learned that she had passed the Novice written test with a respectable score. Everyone was pleased.

At this point, although we had not really spent any time on the Technician portion of the book, I asked her if she wanted to try the test anyway. Yes. They headed back to the testing area and I went back to trying to work my booth. Sometime later someone came out and told me that she had passed her test—I was thinking that not only would she want that new hand-held, but she'd probably want to drive home. Oops. Yes, she passed a test—the Novice written—Element 2. She got a 12/25 on the Technician written—Element 3A. Actually that wasn't bad, considering we had only flipped through that part of the book.

The Duluth/Superior hamfest loomed ahead. I had to get my booth supplies reorganized, and more study-time had to be spent—on evenings when the lengthening twilight called louder and louder to both of us. Friends to play with, bushes to plant, fish that needed catching, antenna projects, a two-wheeler to learn to ride. Nuts! Just two weeks between hamfests and testing sessions.

No, she didn't quite make it that time, either, but she just wouldn't quit despite a number of events—including a house fire—that would have discouraged a lot of people.

Finally, on the 4th of November, 1996, Chandra passed Element 3A and received her certificate. A few days later we learned that she had received callsign KBØYXB, and a few days after that she actually received her license in the mail—surely a big improvement over the long wait many of us have experienced in the past.

As I became more sanguine about Shorty's prospects I realized I would have to produce at least a two-meter rig that she could use. She was so confident of my ability to provide something that all her pop-can money had already been earmarked for a new bicycle. So I dusted off an old crystal-controlled rig that had been at the back of the shelf for a few years. After replacing one crystal, cleaning, and realigning, it looks like it should give her good service. By the time this article is in the mail she should be set up with the old rig, a borrowed power supply, and a flexi-j antenna at her mother's house.

In the meantime she has already used it in a minor emergency. The phones went out while she and her baby sister were here so she was able to call me while I was driving around at my day job. She relayed the correct phone numbers to me and I was able to make the call to get the phone repaired.

So what does it take to get a new ham in the family? An interested student, a willing teacher, a time and a place to study, and appropriate materials.

Was all the effort worthwhile? We think so. And it sure is handy to have another ham in the family. She is starting to talk about Element 1A—the code. When she passes that I guess it will be time for Dad to check the back of the shelf for an HF rig!

A note from Chandra KBØYXB: If you want to do good, you have got to study hard every day. If you do not pass a test, you have got to study more 'til you can pass the next time. It is like learning to ride a bike—you have to keep doing it 'til you do not need your training wheels anymore. 73s.

Riding The Airwaves with Alpha and Zulu is available from Artsci, Inc., PO Box 1428, Burbank CA 91507. Phone (818) 843-4080 or FAX (818) 846-2298.

Mini-Grid DXpedition to FM13

Sand, sun, & almost too much surf!

Robert "Greg" Robinson KB4NVD
208 Dogwood Acres
Hampton TN 37658

I had been wanting to go somewhere special to operate for a long time, and on the weekend of August 12, 1995, it finally happened. Mike N4OFA and I had been very busy at work and weren't sure that we would actually be able to go until the afternoon of the day before—but we were at last able to make it down to FM13 for a weekend of operating and sunshine. Why FM13? Well, this is a rather rare grid square to work because 95% of it is out on the water and the remaining 5% is loaded with mosquitoes!

We drove down to North Carolina Friday afternoon and found the closest campsite was about two miles into FM14. After ten hours of driving from east Tennessee we figured that was close enough. Mike was too keyed up to sleep after setting up the camper, so we drove on down to FM13 to scout the area for potential operating sites. We found a parking area at Fort Fisher State Recreation Area that looked good and gave it a try. There was a meteor shower that weekend, and we thought there would be more operators on, but after many unsuccessful CQs on 144.200 we gave up. We did see some pretty good shooting stars, though, before we headed back to the campground for some rest.

Saturday morning found us roasting inside the pop-up camper with the temperature in the high 90s and humidity to match, but we set up in time for the afternoon passes of RS-10. We found the parking lot packed full (not deserted like it was after midnight) and decided to operate right on the beach (there is four-wheel-drive access). "Hey Mike," I said. "This is why I really brought the Bronco!" Mike was a little skeptical but was willing to go along with it. We made it out a ways but got caught in one of the softer areas behind the dunes. We were almost too late for the first pass of RS-10, so we set up for it right on the spot. That pass netted three Qs.

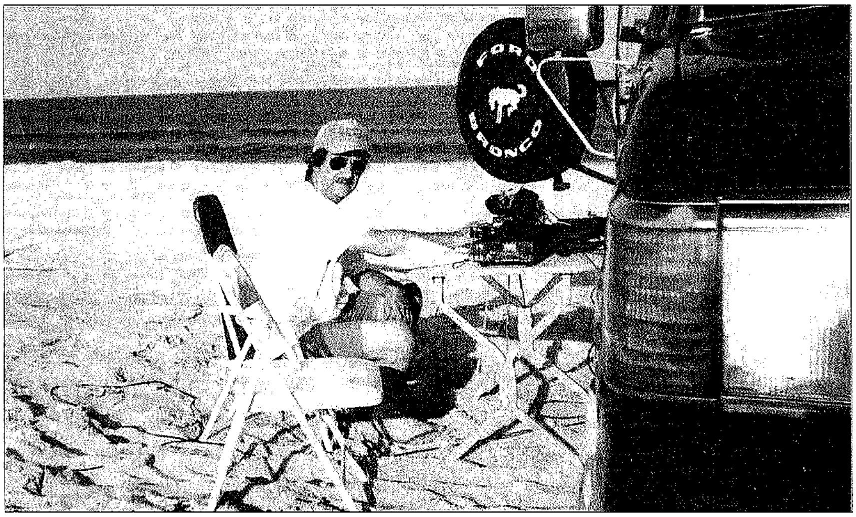


Photo A. N4OFA on 2m CW.

After the pass, we relocated about 15 yards away, right over the dune next to the beach. I lowered the air pressure in the tires to give them a better footprint in the sand and drove around to the beach access. The dunes are very fragile and prone to erosion; no driving on them is permitted. Special crossovers are marked for access out onto the beach. Mike carried the 10m turnstile over and picked out a great spot. We set up all the equipment and took a swim to cool off—the heat index was over 110 degrees. We got out of the water in time for the next pass of RS-10 and worked four stations this time.

We got so caught up in operating that we stayed until 11 p.m., but were finally driven off the beach by hunger and thirst (I was drinking melted ice from the cooler and Mike actually ate part of an MRE I had brought). We made a fair number of Qs to the north, up into FM19

and such. To the east we completed a schedule with Carl AA4H (EM86) back home in east Tennessee. He had wanted to come along but decided he would rather work us while we were down there. Nothing was heard to the south.

Sunday, the heat index went over 115. We took the *big* cooler with us this time, and all the food. We called CQ for a long time before we had any takers, but once we'd worked a few, the word we were on spread quickly. We had a great opening into Florida as the evening wore on, and worked 29 stations.

Murphy strikes again

EL98 seemed to be the center of the other end of the opening. After a long run of stations I finally had to have a break. Mike was going to do his CW magic and I was going to drink a gallon or two of water. I went around to the back of the truck where the cooler was and found the sand firm and moist. Hmm, this isn't right. Did Mike spill the cooler and not tell me? I went and got a flashlight, and holy cow! A wave had washed all the way up to and around the cooler. There was sea foam about ten feet from the truck. Murphy was here—using the name of Hurricane Felix. High tide was in and with the boost from the hurricane the waves were going to come up a *lot* higher than on the previous night. Right around the truck, it looked like.

I had visions of what the XYL was going to say: "You lost the Bronco but saved the *logs*?" Mike and I broke the station down in no time flat and were set to abandon the antenna. We moved the truck up away from the water and watched to see just how the waves were going. We decided that it would be OK to take the time to get the antenna and then get out of there. Mike walked ahead checking the progress of the water while I followed in the truck.

There was just a narrow strip left to drive on. When I got near the crossover I hit the horn and blasted off the beach without letting off the gas. Mike got out of the way pretty quick and caught up with me on the other side of the beach access. This was not a time to get stuck!

Mike and I had a great time operating from a rare grid and want to go back. We have identified some things to improve on, such as more power on 6m, and more bands. Also, the 10m rig had some problems that kept us from being effective on mode A. Being able to use headphones and control the volume (which was stuck wide open) would have been great.

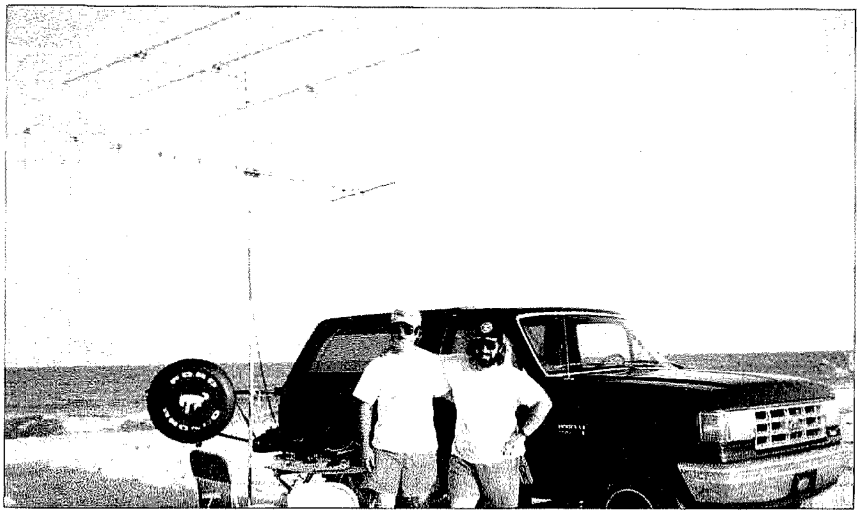

Photo C. *Mike N4OFA and Greg KB4NVD, portable in grid FM13.*

We may not have worked all that many stations, but the ones we did seemed pretty happy. For those in Florida who were wondering why we went off the air so abruptly, now you know why. The farthest station worked on 2m was Jordan WB2QLP in EL96, 538 miles away.

Many thanks to those who helped with equipment and spotting us on the various DX clusters.

The stats

Location: Grid FM13, Fort Fisher State Recreation Area, North Carolina

Operators: Mike N4OFA, Greg KB4NVD

Bands: 6m, 2m and mode A satellite

Equipment: Ten-Tec Scout w/ Ten-Tec 6m transverter; 3-el beam; Kenwood TR-751A; Mirage 160W brick; 10-el beam & Larsen 5/8-wave 2m mobile (uplink antenna for RS-10); HTX-100 10m (for mode A rx); turnstile

Pulling them in

•On 2 meters we worked 47 stations in grids EL88, 96, 97, 98, and 99; EM86, 90, 93 and 94; FM03, 05, 07, 08, 14, 15, 18 and 19.

•On 6 meters we worked 4 stations in grids EM94; FM03, 05.

•We worked 7 stations through the RS-10 satellite, and 2 stations through the RS-15 satellite.

Limit Morse Code Testing to 5 Wpm

For any class of amateur radio license.

Guy A. Matzinger KB7PNQ
503 Dubois Street
Cheney WA 99004-1325
E-mail: guym@on-ramp.ior.com

Amateur radio is constantly referred to as a *hobby*, but it has regulations that are more severe than some professional organizations require for association. Why does a spare-time activity, pursued for pleasure or relaxation, insist that high-speed code proficiency must be demonstrated before a license is issued to use other modes and all the amateur spectrum? I believe these code requirements, with their subsequent marginalizing effect, are crippling the hobby.

The FCC acknowledges, in Form 610 (back page) "Notice to Physician," that five wpm is all that is required to meet International Regulations, but that the FCC supports 13 and 20 wpm code tests because the amateur radio service "strongly desires to preserve communications by telegraphy." How do high-speed code tests "preserve" CW? No one is advocating eliminating Morse code from amateur radio—and there is nothing in Part 97 that stipulates you must operate CW at any *standard* speed ... I wonder if I can convince the State Patrol I'm speeding in order to "preserve" my car?

While telegraphy may have been the dominant form of communication sixty years ago, today's interactive electronics have created a fundamental shift in the abilities and desires of amateur operators. Any organization that fails to recognize these changes, and dismisses or diminishes the technical advancements that are evolving around the world, is either naive or blind to mainstream concerns. Amateur radio must face the reality of tomorrow's technology, and the need to change or risk losing participation in the future.

The solution is politics and Congressional legislation. My goal is to collect 5,000 or more signatures of support for a petition to eliminate Morse code testing for *any* class of amateur radio license—or limit such tests to not more than 5 wpm. In order to obtain a fair hearing on this subject, I will personally take the petition before the Telecommunications Commission in Washington DC. In the meantime, I will continue to solicit the support of other legislators for this cause.

> ***"I wonder if I can convince the State Patrol I'm speeding in order to 'preserve' my car?"***

Radio spectrum is generally defined as the range of electromagnetic frequencies between three kilohertz and 300 gigahertz—and today is considered one of the nation's most valuable economic resources. The federal government determines the general uses for the radio spectrum, allocates bands of frequencies and then assigns licenses to specific users. However, this regulatory system has lent itself to abuse by special interests with the American public as the perennial loser. The case for reforming this failed regime is compelling, but it will take political action in Congress (or even the courts) to replace existing regulations. Most FCC processes are prone to delay—a result of good old-fashioned bureaucratic practices—and any attempt to correct this systemic problem is meet with further procrastination, equivocation and seemingly endless delay or even silence.

In 1927, Congress was persuaded to establish a "public interest" communications licensing scheme and in 1934 the Public Interest Standard was initiated so government would have a legal basis for controlling all licensing activities. The Public Interest Standard allowed regulators to engage in both industrial policy and political favoritism. Even today, the FCC does not have a definition for "public interest" and the "standard" (still in effect over 60 years later) is exactly whatever three of the five FCC members say it is. Nothing is ruled out.

The present amateur radio licensing structure is grounded on government-sanctioned policies designed to suppress participation. Complainants have continually criticized the inefficiencies and fundamental unfairness of such a system and with almost 90 percent of the US amateur radio community denied access to *all* of the amateur bands, efficient use of technological advancement is seriously impaired.

It is helpful to recall that in 1934 the telegraph was still the dominant form of communication and in the midst of the Great Depression, many amateur radio operators constructed their own equipment. The analog technologies of the day dictated the form and function of communications. Today, digital

technique known as Code Division Multiple Access (CDMA) presents a massive wideband increase in efficient use of spectrum. Other compression techniques in spectrum management have opened up huge new segments of spectrum and the old approach of the government husbanding scarce spectrum and tightly regulating its use no longer has a valid basis.

The obsolete 1934 Act does not offer the flexibility or provisions to address the innovations and technical changes that are transforming social development globally. For over 60 years, the government's bureaucratic decision-making has been based on the assumption that communications technology would remain essentially static—an assumption untenable for the 21st century.

Whether today's technology becomes a dream of deliverance or a nightmare of disappointment often depends on what you expect. The information superhighway isn't a highway at all. It's a medium we're all in, all the time, and it gives us powers of information and communication we haven't begun to harness. Today's computer hardware and software tools give us the freedom and the ability to reach anyone or anything from anywhere at anytime. They will change the world in ways we can't imagine. And that's a good thing, even if those pickle-headed politicians, bureaucrats and some amateur radio organizations don't get it.

The "Infobahn" is taking to the airways as a host of wireless technologies mature. Utilizing the newest computer tool, live voice audio-conferencing over the Internet is now possible. The software cost is less than $100 and with a SLIP/PPP account, hourly on-line costs are less than three cents per hour (based on $20/mo and 8,760 hrs/yr) to anywhere in the world, anytime, day or night. A fiber in the fiber-optic network can simultaneously carry 37,500 separate conversations. The marginal cost of transmitting a call is literally zero. With these facts and considering the rapid removal of the sight barrier, how are you going to entice the younger generation into amateur radio in sufficient numbers to ensure the future of the hobby?

The truth is, you will never interest enough young people for this hobby to grow unless the Morse code requirement is either eliminated or limited to not more than 5 wpm for any class of license. Why should they be interested in an obsolete method of communicating when the technologies of the future challenge them? Presently, less than 5% of the total US amateur radio population is under 21 years of age. Unless this hobby is made more inviting to the youth of this country, the young will stay away.

A few years ago the IARU (International Amateur Radio Union) formed a CW Ad Hoc Committee to study the feasibility of maintaining or deleting RR2735, better known as the International Morse Code Regulation, which does not have a particular phraseology demand or definitive speed stipulation. The three members of the committee were from Great Britain, New Zealand and the US. The US representative was American Radio Relay League Exec. VP David Sumner K1ZZ. The results of their report were predictable—do nothing.

Apart from the question of whether the emotional ambiguities add up, there is something fallacious about this study. Is it the inclusion of a reference to the 1979 World Administrative Radio Conference (WARC-79) where the ARRL contended that its membership overwhelmingly requested "no change" to RR2735? Is this the reference (now more than 16 years old) constantly used by the FCC to reject all petitions that address Morse code testing practices? Or is it the admission, on page 17, that: "Standards will fall and the result could be congestion by technical-elite operators incapable of self-controlling their occupancy to achieve the best communicating results"—however, again, the "Standards" are never defined.

The statement on page 9 seems contradictory: "Yet it would be inappropriate to require, in an avocation (the dictionary defines avocation as a hobby) that all operators be capable of speaking and understanding a common spoken language"—yet they demand that everyone learn Morse code. Isn't communicating, regardless of method, speaking to others? Interesting admission on page 7: "With limited exceptions, radio amateurs today do not use Morse code to get important messages through under adverse conditions." They go on to say: "It must be remembered that many, if not most amateurs, use more than one

mode." Then why is a single mode with test speeds in excess of 5 wpm imposed on US amateurs? Doesn't this selectively limit participation?

New Zealand, with the support of Great Britain and others, proposed at WRC95 elimination of RR2735. The ARRL opposed the move and claims the US position was "in alignment" with their views.

Several years ago, the ARRL effectively lobbied and was primarily responsible for creating the present amateur licensing structure. It did so with but one thought in mind—self-serving exclusivity. This is the classic case of the minority controlling the majority with bureaucratic help. Keep in mind that the membership portion of US licensed amateurs in the ARRL organization is estimated to be *less than* 25% of the total US amateur community. Hardly majority representation of licensed amateurs.

Factoid: As of March 1995 the total ARRL membership is acknowledged at 172,752. Subtracting those who are not US licensed operators, the league's claim that they represent the majority of amateurs is estimated to fall 2 to 3 percentage points below 25% of the total number of 700,000+ US amateurs.

It appears to me that the chief concern of the ARRL board of directors should be how to extricate themselves from an egotistical blunder initiated several years ago by those in their organization whose sole purpose was to create an exclusive club and selectively limit participation in the hobby of amateur radio.

It's a shame the ARRL doesn't understand that their oppressive incentivized licensing policy and the torture associated with code testing is the major reason their own growth is limited. Their attitude reminds me of the Swiss watchmakers who, having invented the quartz watch, failed to pursue the technology—they went from 46% to 10% of the world market. In this technologically changing world, recognizing the need to change is essential for any organization that wishes to avoid obsolescence.

Nothing mandates that amateur radio operators, using CW, send code at a specified "standard" speed. Why then are 13 and 20 wpm code tests jammed down our throats? Code testing requirements are blunt powers that enable a minority organization to coerce the majority. It is estimated that less than 10% of the amateur community use manual telegraphy on any regular basis.

"The 'standard' is exactly whatever three of the five FCC members say it is."

Why are *all* petitions that propose any change to the Morse code testing syllabus rejected by the FCC? They continually trot out the same tired war-horse with the overused rationale that code requirements were developed with the desires of the amateur community—the who, when and why this occurred is never answered. Is this just a curious irrational coincidence or an intentional cabal—or are those who review petitions without a sense of moral responsibility?

Enough is enough of these politically generated self-serving policies. We need commonsense regulations, not government pandering to organizations who lack consideration for the opinions and rights of others. Maybe it's time these "bureaucratic cronies" and arrogant disciples of the ARRL retired?

Amateur radio is a hobby and is supposed to be fun for everyone, not just for a select few who consider HF bands their private domain in an exclusive club created by a licensing arrangement deliberately formulated to exclude the majority. If you are tired of the emotional cost, the endless frustration and the contemptuous attitude of those who support the present Morse code testing practices, you obviously no longer harbor the delusion that the code tests are for your benefit. For far too long, the majority of amateurs have been stymied, spurned and insulted, barred from total participation on all amateur bands by political favoritism initiated by a minority organization.

Current code testing practices no longer facilitate the society of amateur radio operators. Old ways may have been adequate years ago, but to survive into the future, amateur radio must face the reality of today's communications technology and be responsive to the innovations and ingenuity that even now is evolving around the world.

NEVER SAY DIE

Continued from page 4

things which benefit all of us and for which, therefore, the hat should be passed for their development and maintenance.

In addition to military protection, a large contributor to our quality of life lies in developing and maintaining our industrial strength. Business. And here one obviously critical factor is the education and skills of our people. Our workforce. And this is every bit as important in the long run to our quality of life as the maintenance of our military strength. So yes, we need to pass the hat to pay for the education of our people. Note that I didn't limit that to children.

Once we graduate from our "free" public school system we are forced to pay for our own further education, so we make that investment because we see the potential for a personal benefit. But, in fact, everyone benefits to some degree, so perhaps it's reasonable to include some public contribution to further education.

Of course, one of the major problems with the government collecting for any service is the inefficiency of this funding system. Between administration, the natural application of Parkinson's Laws of growth to any government institution, and fraud, we're lucky to see 10 cents of any tax dollar collected end up where we intend it. There is plenty of room for improvement of this function of the government.

While it is in the interest of the public to keep government costs low, there is also an interest in educational efficiency which will permit the maximum transfer of information and skills to individuals at the lowest cost. And fighting all this is the momentum of the present bureaucracy which has gradually accumulated and solidified around the American school system, making it difficult to even consider major changes.

From what I heard during Economic Development Commission hearings from professional educators and college presidents, and what I've read as a result, I believe it's possible for our school costs to be cut at least in half—while, at the same time, we improve the product enormously. College tuition, using a plan I've proposed, can be eliminated entirely, with a concomitant reduction to three years and a resulting development of skills and information that's double to triple the current results.

Of course, with colleges, this would mean a reduction of their investment in paid sports teams and amenities such as golf courses and airports, the things which have driven the cost of some college "educations" over the $100,000 mark. The actual amount of education money buys is questionable, and not supported by international surveys.

Indeed, as I've pointed out in my *Making Money, A Beginner's Guide*, a college education equips you mainly for a job which will never make much money. Few successful entrepreneurs bother to finish college. Little that is taught (?) in today's colleges has any relevance to success in small business, and that's where the money is.

Building Skills

After reading Dan Greenberg's book, *Free At Last – The Sudbury Valley School*, I got all excited over what looked to me like possibly one of the best schools in the world. So I sent for, and read, five more books about the school. It's only a couple of hours from where I live, so I should get down there and see for myself what they're doing.

I love the idea of kids being able to learn what they want, without there being any formal curriculum: courses, grades, tests, and so on. In reading about the graduates I was struck by their success in a wide variety of fields, but I was disappointed that none that I read about were *outstandingly* successful. I expected to see some amazing successes.

I know you're not going to believe this, but this almost got me to thinking. The missing element, I suspect, is the taking advantage of children's natural curiosity by exposing them to a wide assortment of ideas as part of the plan, and not just hope that fate will do the job. Some of these kids might have a ball with amateur radio, if they knew about it. And ditto many other hobbies and interests.

When I was in the navy going to electronics school a submarine captain came in one time and gave us a talk about the submarine service. I had never considered it before that. So I volunteered for subs when graduation time came. I was disqualified on the medical, which is a fascinating story in itself, but I lied about it and went happily off to get myself killed in a 300-foot-long pipe.

In my *Declare War* book I proposed establishing a school much like the Sudbury Valley School, except that I wanted to have videos available for kids which would explain what the fun and benefits would be if they got involved with learning this or that subject, or developed some skills.

In my book I didn't list all of the skills I could think of, so this time I made a more comprehensive list of skills that I think would be of value for kids to build. Look over the list and let me know what I've missed.

How many of these skills had you mastered by the time you got out of college? By "master" I really mean to be at least adequate at. Most of these skills require instruction from an expert. I've found that it doesn't take very long to get as good at some skill as the average person in the field. I generally like to take the extra time and effort to be better than 90% of the people with that interest. The next 9% takes ten times as much effort, so I generally don't bother. I like to be

Hamtronics' TA-51 Exciter Kit

Perk up your foxhunts with this project.

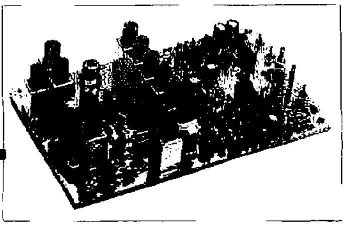

Photo A. The assembled TA-51 exciter board.

Larry Antonuk WB9RRT
P.O. Box 452
Marlborough NH 03455

Over the last couple of years our small foxhunting group had been growing by leaps and bounds. Starting with just a couple of experimenters, our group now numbered over a dozen. We all enjoyed the thrill of the chase, but the main focus of the group was building, testing, and experimenting with new antenna and RDF (radio direction finding) designs.

Hunt troubles

Things had been going well in general, but over the last few hunts we'd had problems. Three of the last five hunts had to be called off or modified because our fox transmitters had failed during the hunts. In one case we were using an old thumbwheel-type handheld as the fox. Apparently the thumbwheel contacts were dirty, causing the transmitter to jump channels intermittently. This made the transmitter mysteriously drop off the air at strange intervals, and caused some trouble for the packet channel the rig was suddenly transmitting on. One of the group then built up a little postage stamp-sized transmitter. This worked OK, but the frequency began to drift as the battery voltage dropped. The hunters with the synthesized rigs were able to follow the transmitter down the band, but those of us with rock-bound rigs were left on the wayside. As a last resort, one of the guys donated an old mobile rig, matched up with a car battery. It was still putting out about twenty watts, so he hid the high-power fox in the next county, using a timer to turn it on right at noon after he returned to the starting point. It was a great idea, but the second time the rig keyed up the high amount of RF got into the IDer/timer, locking it up and causing the rig to go into constant PTT. This made for easy hunting, but after about half an hour the finals burned up—turning our high-power mobile into a QRP rig.

"(Before the TA-51)... our frustration level was running high..."

At this point our frustration level was running high. We were spending more time fixing our crippled foxes than we were building antennas. At our next informal meeting we came to the obvious conclusion—we needed a decent fox. Of course, no one stepped forward to donate a new handheld. No one wanted anything to do with the flea-power one-transistor boards. A few mobile rigs were offered, but they were too big to mess around with. We ticked off the requirements. The transmitter had to have between one and five watts output for the best use around our area. It needed to be rugged—continuous duty, just in case we had another controller failure. Crystal control was OK, since we always used the same channel for the hunt. And of course, it needed to be reasonably priced (OK, cheap or free would be best).

Enter Hamtronics

One member of the group, who works for a commercial two-way outfit, mentioned the use of a Hamtronics exciter. His company had used several of the exciter boards as fixed transmitters in RF link applications. They were continuous duty at two watts, and met all of our requirements at a decent price. At our next weekly breakfast he

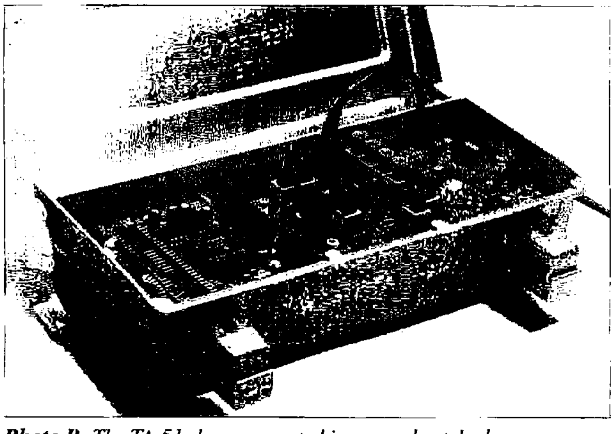

Photo B. The TA-51 shown mounted in a surplus telephone company connection box. The exciter board sits atop the battery pack, with the ADAPT-11 microcontroller mounted in the front of the box.

brought in his catalog, and we chose the TA-51. The TA-51 was the companion transmitter to the R-100 receiver (see *73*, February 1996) designed for repeater or RF link applications. We passed the hat for contributions, and anxiously sent off the check to Hamtronics.

The unit was shipped directly to our resident kit fanatic, so the rest of the group never saw the exciter in unassembled form. It was proudly displayed at the following breakfast—assembled, tuned, and tested. According to the report, the assembly went without a hitch. In appearance the TA-51 looks very similar to the R-100: the same glass-epoxy PC board, the high-quality components, the easy-to-tune coils. The TA-51 uses eight transistors in the RF section, and a single op amp IC for audio processing. Our RF wizard had a service monitor for tune-up, but indicated that standard equipment would make it just about as easy—a voltmeter, a dummy load/wattmeter, and a current reading power supply. The A28 tuning tool is mandatory; there's no other way to adjust those slugs with the square holes. One other point that was appreciated by the builder and the group was the use of a high-quality, ten-turn piston cap for warping the crystal. This made it a cinch to adjust the transmitter frequency right on, as opposed to the single-turn caps we'd been used to on the handhelds and mobile rigs (in addition to being tricky to adjust, the single-turn caps were very susceptible to jarring and bumping—one drop of the fox, and we were off on another channel).

"No problems—even after that ten-foot drop..."

Once it was built and aligned, we took an evening and installed the TA-51 in our fox "cabinet," a surplus telephone company connection box. The box was waterproof, easy to mount or hide, and just the right size for a small handheld or the TA-51, along with the IDer and a large NiCd battery.

New IDer, too

The IDer itself was something of a home-brew device. It was built using the ADAPT-11, a 68HC11-based microcontroller, and programmed to key up the transmitter and send Morse IDs. The transmitter was keyed by toggling one of the 68HC11 output ports, and the audio tones were created by toggling an output port at 1000 Hz, then keying this on and off to create the dots and dashes. Our resident computer guru set up the ADAPT-11 to create a pseudo-random PTT time, so the hunters were never quite sure when the signal would pop up, or how long it would last. In addition to the timing challenges, our guru found that you can vary the power output of the TA-51 by simply dropping the B+ voltage down to 11 volts. His next plan is to raise and lower the output power of the TA-51 intermittently, in order to further confuse the hunters. Once mounted in the telephone company box, the fox is easily hidden or, as in one case, not hidden at all. Mounted at the ten-foot level on a telephone pole, the box fit in so well that most hunters passed by or circled the pole several times before identifying the fox.

While exhaustive field tests are not yet complete, the new TA-51 fox has participated in three hunts with no problems—even after the ten-foot drop from that telephone pole on hunt number two. Perhaps the best measure of success is the fact that the topic of our weekly breakfast discussion is now turning back to how to make better antennas and RDF rigs, rather than how to get a fox we can rely on!

The TA-51 VHF Exciter kit is available for $99.00 from Hamtronics, Inc., 65 Moul Road, Hilton NY 14468-9535. Phone: (716) 392-9430.

Small Loop Design for HF QRP

A practical approach.

Jay M. Jeffery WV8R
3819 Parkdale Road
Cleveland Heights OH 44121

It's nice to be able to make perfect small loops using metal tubing and motorized split stator capacitors, and to be able to weld everything neatly together, but not everyone wants or needs such elaborate antennas. In fact, for QRP operation, the weight and complexity of the very efficient loops is often not desirable. A wire loop, on the other hand, is a light, simple, device that can be built quickly and easily and can be repaired with a few basic tools. It needs only an ordinary variable capacitor, and it's easy to take in the car.

For the QRPer in an apartment, a manually-tuned wire loop hidden behind a wardrobe is more appropriate than a heavy monstrosity that must be operated by means of a control box even though the antenna is only a few feet away. Also, a wire antenna can be put together for just a few dollars—even less if you have a junk box and some leftover furring strips.

It works both ways

To design and build small wire loop antennas, I had to come up with a quick, easy way to estimate the inductance of a wire loop where the length is known. On the other hand, if a specific inductance value is known, the required length would be easy to calculate using the same formula. The range of the formula would have to include loops with a circumference of seven feet to 38 feet. In this range, "small" loops are still small relative to the size of a room or an attic space. Of course, 38 feet may be hard to accommodate, but it is still possible.

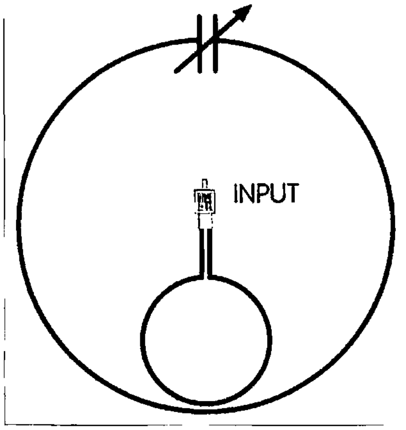

Fig. 1. Circuit diagram.

The simplified formula is a linear approximation of a more complicated formula which can be found in *The ARRL Antenna Handbook*. The more complete formula (slightly modified) is:

$$L = .019S\ (7.353\ \log_{10}\frac{96S}{\pi D} - 6.386)$$

where S is the perimeter of the loop in feet, D is the diameter of the wire used in inches, and L is inductance in µH. This formula can be used for values outside the range given for the shortcut formula.

The simplified formula is L=.45S - .5, where L is the inductance in µH and S is the perimeter in feet. Solving for S in terms of L, we get S=2.22L + 1.11. These formulas are approximate but easy, and close enough for practical use. They assume an AWG #12 wire size but would work for wire slightly larger or smaller. The wire recommended for this purpose is #12 stranded, insulated house wire, cheap and readily available.

More numbers

Given the size of a loop and a capacitance value, the inductance can be calculated for a particular band, or for several bands using the extreme frequencies, L=.45S - .5 and the formula:

$$f = \frac{10^6}{2\pi\sqrt{LC}}$$

where f is the frequency in kHz, L is the inductance in µH, and C is the capacitance in pF. Some useful versions of this basic formula are the following:

$$C = (\frac{10^6}{2\pi f\sqrt{L}})^2$$

$$L = (\frac{10^6}{2\pi f\sqrt{C}})^2$$

The formula that solves for L is appropriate when you have a good variable capacitor and want to determine what size of loop you need for certain frequencies. You simply substitute the L value in the length formula (S=2.22L + 1.11).

Beside the formulas, some rules of thumb are helpful in making small loops. The size of the loop should be large enough to be relatively efficient and large enough to tune easily. For easy tuning, you don't want to be tuning at the extreme values of the capacitor. For efficiency, experience has taught me that a 10-20 meter loop works well if its length is no smaller than seven feet. A 20-40 meter loop should be no smaller than 11 feet. A 30-80 meter loop should be no smaller than 22 feet. For indoor use, a vertical loop is the best choice.

Impedance matching

Small loops require an impedance matching device. The simplest approach is a small input loop placed inside and very near the main loop (**Fig. 1**). In practice, using insulated wire, the lower part of the input loop can be taped to the bottom of the main loop. This allows for fairly close coupling and for added mechanical rigidity. The coax is attached to the input loop and is placed so that it comes away from the plane of the main loop at a right angle. The input loop should be about one-fifth the size of the main loop or smaller, but experiment for your own best results.

Try a project

To show the use of the previous information, let's design a 20 through 40 meter

loop for use in an apartment, a home, or even outdoors (an outdoor antenna would require weatherproofing, however).

Assuming that you have an eight through 100 pF air variable capacitor available, the required inductance can be calculated using:

$$L = \left(\frac{10^6}{2\pi f\sqrt{C}}\right)^2$$

Using the lowest frequency to be used (7,000 kHz) and somewhat less than maximum capacitance (say, 90 pF), the inductance turns out to be around 5.74 µH. Using S=2.22L + 1.11, the length is approximately 13.9 feet or about 167 inches. This would be a square approximately 41.7 inches on each side. A circular loop, using D=C/π, would have a diameter of about 53 inches.

At the higher end of the frequency range, C=18 pF (somewhat more than the absolute minimum). Then, using the formula for f, specifically,

$$f = \frac{10^6}{2\pi\sqrt{LC}}$$

we come up with 15,700 kHz. This means that the antenna should easily accommodate 20 through 40 meters.

Finally, the input loop length is 167/5 inches or about 33.4 inches.

Testing the loop

First, the wire for the two loops should be cut to the calculated lengths and laid out on a wooden floor (or somewhere that won't involve a lot of metal mass). Temporarily mount the variable capacitor in a plastic box or the like and connect it to the main loop. Connect some 50 ohm coax to the input loop and place the loop very close to the main loop.

Now, connect the plug of the coax to a receiver set first at 7,000 kHz. By adjusting the loop capacitor, you should be able to find resonance points. If you have resonance, the background noise will maximize and signals should be easily heard on the band. Note that the resonance points are sharply defined, so tune slowly. If the loop doesn't tune the band, pruning or adding some length should fix it depending on which band is missing. Repeat this procedure for the highest frequency desired—in this case the top of the 20 meter band. If the SWR is too high, try pruning the input loop.

If the size of the loop is satisfactory, then you can design a framework to hold it. Almost any polygon will do, although a circle or an ellipse can be managed by using solid house wire, #12 or larger, which will hold a curved shape. A single mast can support the loop, but a spreader will make it more rigid.

If you think this particular loop is too large, get a larger capacity variable and design another loop to fit it.

Another approach

Another way is to begin with the size of the loop you prefer. Knowing the size, you can compute the approximate inductance. With the inductance and the frequencies, you can determine the size of the variable capacitor you need. There are variable capacitors available from several places including Surplus Sales of Nebraska, Mouser, Ocean State, or Antique Electronic Supply. Ocean State Electronics has some excellent trimmers that can be used. Trimmers give you a wide choice of capacitance ranges and breakdown voltages, and they are harder to tune, even with an alignment tool—but they *are* relatively cheap.

Capacitors obtained from an old tuner work well as long as the power levels don't exceed 10 or 15 watts. Capacitors with higher breakdown voltages are required for QRO.

Don't make the loop too small!

I recommend (from experience) that loops should be 8% of the wavelength of the lowest frequency you intend to use or more. About an eighth of a wavelength is better, but the antenna gets rather large, especially for 80 or 160 meters.

Finally, here is a warning: Don't forget that an antenna should not be touched while it is in operation. Even at low power levels, not to mention high ones, there is danger. Please take safety precautions. A loop sitting on the floor in your house is very accessible to pets and people.

On your own

You have enough information now to design, test and build your own small loop antennas—the best way to learn about them. This way you can get exactly the kind of small antenna you want. 73

Power Monitor/Distribution Panel

Build this early warning system.

J. Frank Brumbaugh KB4ZGC/W4LJD
Box 30 - c/o Defendini
Salinas PR 00751

Very few station power supplies or transceivers are equipped with meters to monitor voltage and current, yet knowing the level of both is important and often provides the first warning that something is wrong. Of course, omitting these meters reduces the cost and size of power supplies, many of which will be tucked out of sight under the operating desk or on a high shelf and seldom glanced at after being turned on. Also, as we all know, the front panel of the usual commercial transceiver teems with so many knobs, switches, and push-buttons that there's no room for these useful voltage and current meters. Omitting them also reduces manufacturing costs.

Every ham should know whether the regulated voltage from the power supply is steady and at the correct level. An unusual variation is a warning and should be investigated immediately.

Murphy's Law being what it is, occasionally the power supply regulator can quit, allowing the output voltage to soar to dangerous levels. Although some commercial power supplies contain protective circuits to prevent this, some do not. Also, many home-brewed regulated power supplies may not be protected from the results of regulator failure at all. Therefore, to protect your transceiver as well as your bank account from major damage, this panel includes a means of monitoring the DC voltage and automatically disconnecting it from the transceiver should the voltage exceed a safe pre-set level. A fuse alone would not open the circuit rapidly enough to prevent damage, although a fuse should be included in the positive DC lead.

Because many ham and/or satellite stations have more than one transceiver as well as many other pieces of equipment, separate parallel branches should be available to distribute DC voltage to all present and planned equipment to be powered from the main station power supply. Additional "goodies" can easily be incorporated, such as regulated low voltages to power accessory equipment.

The panel described here provides all the amenities described above. It can often be constructed entirely from a well stocked junk box, but for those few who lack a well filled one, I'll tell you where to purchase the most expensive components, the meters, for little more than pocket change. Except for the panel itself, which can be a flat panel, an aluminum chassis, or a home-brewed enclosure, the total parts cost should not exceed ten dollars. This is very inexpensive insurance for expensive equipment which also provides maximum flexibility in monitoring and routing DC operating voltage to your equipment.

The circuit

Fig. 1 illustrates the schematic diagram of this panel. Aside from its primary functions of monitoring, distributing, and automatically disconnecting power from the load(s), should the voltage soar out of bounds, it includes optional but very handy outputs at the three most useful regulated voltages often needed for accessories but not directly available from the station power supply.

Regulated DC voltage from the station power supply is applied to the positive and negative input terminals of J1. A barrier strip is shown, but separate DC input and output connectors can be used to replace the barrier strip and eliminate the exposed voltage terminals. This input voltage is bypassed where it enters the panel by capacitors C1, C2, and C3, which eliminate incidental noise or spikes generated externally or internally. Positive voltage from J1 passes through fuse F1 and the normally-closed contacts of relay K1, then through current shunt R2 which is in parallel with ammeter M1, to the power output terminals on J1. Negative (ground) terminals on J1 and all grounds in the panel are connected to the station ground. Output terminals for three distribution lines are shown. You may install however many you wish. Meter M1 will display the total current drawn by loads connected to the output terminals when they are turned on. Positive voltage at the output of the shunt R2 is also applied to the suppressed-zero, expanded-scale voltmeter M2. This meter indicates a narrow range of voltages around the nominal power supply voltage as chosen by the builder. This will be explained later.

The input DC voltage is also tapped off between fuse F1 and the moving contact of relay K1 and applied to the automatic voltage monitoring circuit consisting of R1, D3, Q1, and K2. When R1 has been properly adjusted and the DC voltage exceeds the level chosen by the builder, D2 avalanches and applies a positive voltage to the base of Q1, driving it into saturation. The coil of K2 is the collector load for Q1, whose collector current energizes K2 and closes its normally open contacts. This applies operating voltage to

relay K1. K1 then switches and opens its normally-closed contacts, removing the DC input voltage from all output terminals as well as the panel monitoring circuits, and both meter needles will fall to the left end of the scale. The input voltage, now somewhat excessive, maintains both relays in their operated positions, without damaging the monitoring and control circuit, until the power supply is turned off. Because the normal elapsed time between a power supply malfunction and its being turned off by the operator will probably be only a few seconds at most, the monitoring circuit will not be adversely affected.

Three optional three-terminal regulators, U1, U2, and U3, derive their input voltages from the input side of shunt R2 and ammeter M1, so the current drawn from these regulators will not be monitored on M1. Voltages of 5, 6, and 9 are suggested as being the most useful if this option is included. Each low regulated voltage should be available at two or three parallel-connected output connectors, such as coaxial power jacks, to provide flexibility in powering small accessories.

Although not indicated in **Fig. 1**, a low-cost AC line voltage monitor which indicates AC line voltage from 90 to 130 VAC is recommended if you have space (see "Line Voltage Monitor," *73*, January 1996, page 86). Unfortunately, the schematic diagram was inadvertently omitted and is reproduced in **Fig. 2**. This will add about three or four dollars to the overall cost of the panel, and will provide a warning if the line voltage falls too low or rises too far.

Even if you have a large budget and have your heart set on nice, neat, high tech digital meters to use for M1 and M2, I very strongly recommend using analog meters instead. A digital meter, while extremely accurate, must be inspected closely to see just what its indication is. An analog meter merely needs a quick glance at the position of the needle to assure you that all is well.

Because new analog d'Arsonval meters are extremely expensive, I suggest you order a "grab bag" of five very high quality surplus meters from: Fair Radio Sales, Inc., PO Box 1105, Lima OH 45802. Phones: (419) 223-2196 and (419) 227-6573. 24-hour FAX: (419) 227-1313. Ask for Catalog No. WS97.

The meters you will receive will be of their choice, not yours, but all will be high quality, name brand meters, with basic movements ranging from 100 μA or less to 1 mA; at a couple dollars each for top quality meters, you can hardly go far wrong.

Fuse F1 should be commensurate with the maximum current your power supply is rated to deliver. Most 100 Watt transceivers draw about 20 Amperes on peaks, so a standard 20A fuse is sufficient. However, if you use modes requiring constant full power output, a slow-blow fuse or a standard fuse rated a bit higher might be the best choice.

Relay K1 can be single or double throw as long as there are closed contacts when the relay is not energized. The contacts must be rated to switch the maximum current expected to be drawn by the load. A DPDT relay with 10 Amp contacts can have the contacts connected in parallel to form a 20 Amp relay. Its coil is rated for 12 VDC.

Relay K2 has very little work to do and its contacts handle only the coil current of K1. A small DIP relay is ideal, and half-Amp contacts are sturdier than needed.

Construction

Just how this panel is constructed depends entirely upon the size of the panel or enclosure and on the size of the meters. The only cautions which should be observed are when connecting C1, C2, and C3 directly across the point where the DC voltage input is applied to the panel, and when routing the heavy wire lead between R2 and the K1 contacts and from R2 to the output terminals on J1. These two leads must connect to the ends of the shunt R2.

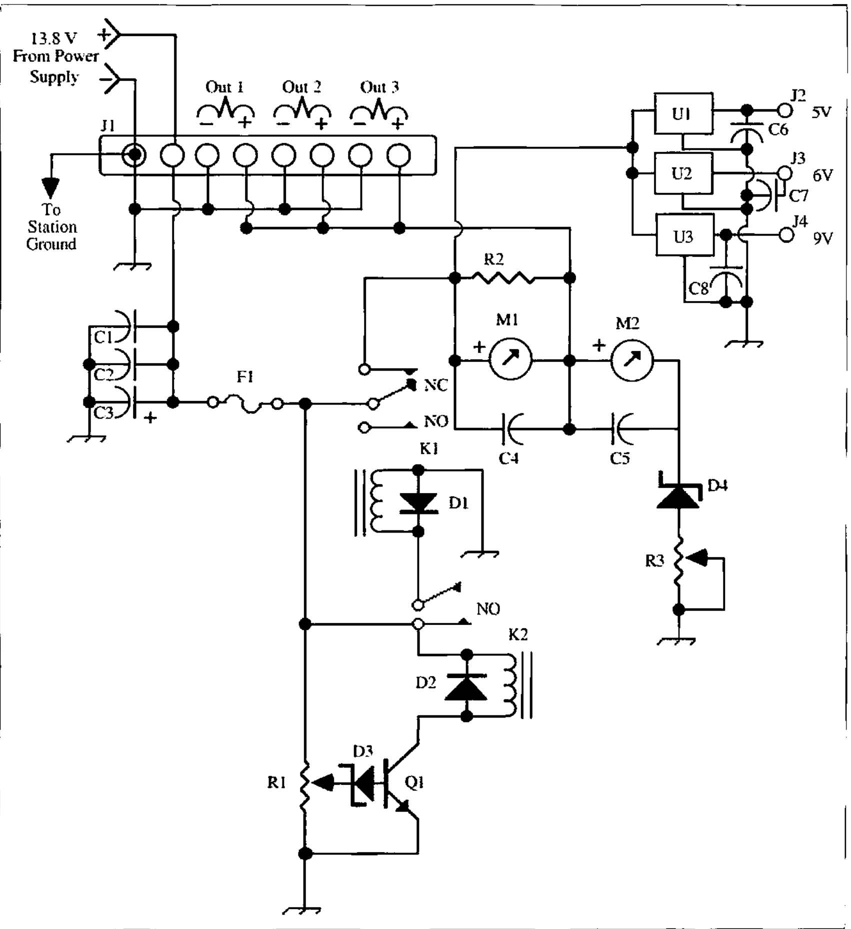

Fig. 1. Schematic diagram of the power monitor/distribution panel. Relays shown not energized.

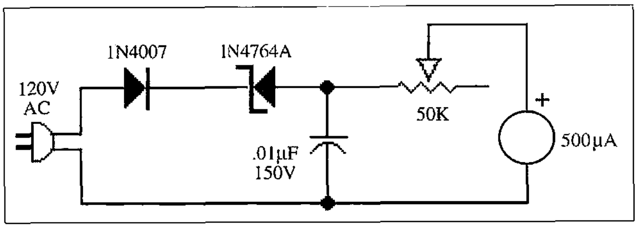

Fig. 2. AC line voltage monitor (optional).

Because there's little chance that the scales on the two meters you use will be exactly what you need, they cannot be mounted until the scales have been modified to fit your requirements and any internal rectifiers, shunts or multiplier resistors have been removed. To accomplish this you will need far more information than can be included here, but do not despair! (See "Use Those Surplus Meters," 73, January 1992, page 42.) If you do not have a copy or cannot locate one locally, back issues and photocopies of articles can be purchased from the publisher. That article has all the information you'll need to modify many different styles of meters.

When you have made the shunt R2 for M1 and changed the meter scale, both can be remounted and wired into the circuit. When M2 and its associated zener diode D4 and voltage adjust trimpot R3 have been determined and the meter scale modified to meet your requirements, these components can be mounted and wired into the circuit.

Before moving into the next section, check all your wiring and all soldered connections. Adjust R1 and R3 to place their wipers at the ground end of rotation.

Adjustment

Temporarily apply the DC output of your power supply to the input terminals of J1, maintaining correct polarity. Place the panel in the same relative position it will occupy when permanently installed, measure the DC voltage between the positive terminal of M2 and ground with a DMM (preferably) or accurate analog multimeter, and note the exact voltage. Adjust R3 so the voltage indicated on M2 is the same as that just measured. Remove the voltage from J1.

Determine the maximum DC voltage your transceiver or other load can withstand and still operate correctly. This will be found in the list of specifications in the operating manual.

Apply a source of variable, filtered DC voltage capable of being varied from below to slightly above the maximum safe level, and set that voltage from the variable source with your DMM or multimeter. Slowly adjust R1 and listen for the click when K1 energizes. Back off R1 until K1 clicks again as it opens, then readjust RI until K1 just energizes. Do this carefully and do not overshoot.

Now, slowly vary the input voltage a bit lower, adjusting very slowly so you can hear K1 click as it operates. Measure the input voltage again with your meter. It should be extremely close to the trip voltage set by R1. Very minor adjustments, made extremely slowly, of R1 may be required until you are sure the DC voltage will be interrupted should it exceed the tripping level you have established. This completes all adjustments. Operation will now be automatic.

Operation

Install the panel permanently where it can easily be seen from your operating position. Connect the DC input and output cables from the station power supply and other equipment to the panel connectors. When all cables have been connected and you are certain no errors have been made, turn the power supply on. The output voltage will be displayed on meter M2.

Then turn a transceiver on. The current drawn in the "Receive" mode will move the needle of M1 slightly up the scale. This will probably not indicate the exact value printed in the specifications. The latter is not exact and transceivers vary among themselves. Also, analog meters usually have a rated accuracy of ±2% of full scale.

Connect a dummy load to the transceiver, and plug in a key. The current indicated by M1 will be close to that cited in the specifications with the key closed. If you do not have a straight key, either a paddle or mike will serve to kick the needle on M1 around to let you see that all is working properly.

Now, turn everything off, get a cold "807" from the refrigerator, lean back in your chair and admire your handiwork. You can be secure in the knowledge that a glance at the meters will be reassuring, and that your expensive rig(s) will be protected automatically should Murphy interfere with your power supply regulator.

Parts List	
C1	0.001 µF ceramic disc
C2, C4, C5, C6, C7, C8	0.1 µF ceramic disc
C3	22 µF 25VDC electrolytic
D1, D2	1N4148
D3	5.6V 400 mW zener diode
D4	10V or 11V 400 mW zener diode
F1	Fuse
J1	Barrier strip or builder's choice
J2, J3, J4	RCA jack or builder's choice
K1	SPDT or DPDT 12V relay, NC contacts
K2	SPST relay, NO contacts, 12V coil, DIP or similar small relay
M1	Ammeter
M2	Voltmeter
Q1	2N3904 or similar NPN small signal transistor
R1	10kΩ trimpot
R2	Shunt
R3	Trimpot voltage adjust
U1	7805 regulator
U2	7806 regulator
U3	7809 regulator

One thing you should remember—if you notice the needle on M2 wiggling up and down on voice peaks or while keying—no regulator is perfect, and because M2 is an expanded scale meter these excursions are much smaller than they appear at first glance. 73

The Insta-Flex 2 Meter Yagi Beam

Right at home in awkward places.

Darwin Ogden KB7WOS
790 West 800 South
Richfield UT 84701

If you have ever transported a yagi beam, or carried it through woods or underbrush, you know how the elements are always catching or getting damaged on something—so you will love the Insta-Flex Yagi Beam. It's inexpensive, easy to construct, and the elements can bend all over the place and still return to their proper positions.

The thing that makes the flexible elements and flexible gamma match possible is an everyday metal carpenter's tape measure. I had thought about using the tape measure for some time. The problem was designing a flexible gamma match. Thanks to suggestions from Dean Harmer WB7PRB and Berry Bradley WB7REL, the combination of flexible elements and gamma match, coax capacitor, and PVC boom came together.

"The elements can bend all over the place and still return to their proper positions."

I keep my beam in a fishing rod carrying tube behind the seat in my pickup. A cardboard mailing tube or PVC pipe would work just as well.

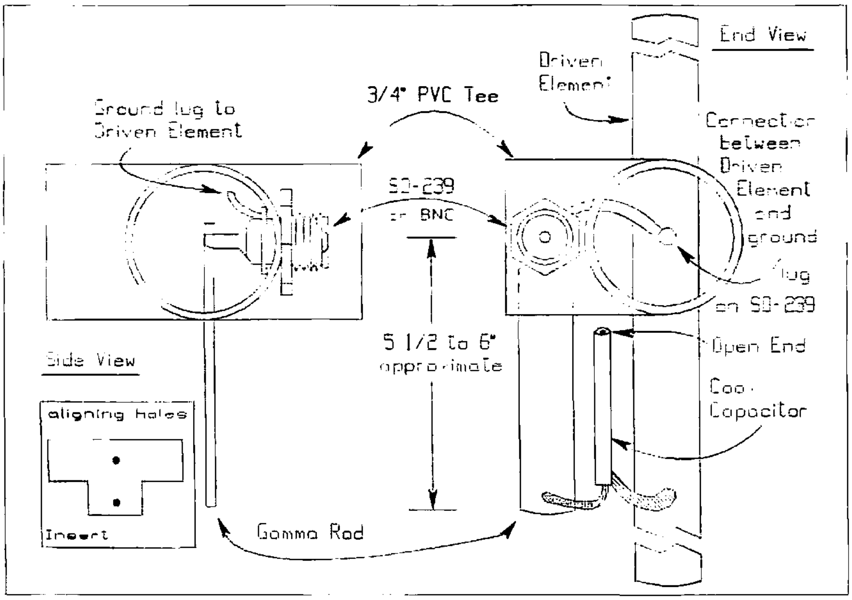

Fig. 1. Tuning the Insta-Flex Yagi, method A.

Setup is instantaneous: Just pull it out of the tube and the elements will spring into position. Connect the coax to the antenna and your radio and you're on the air.

Construction

As shown in **Fig. 1**, I drilled a hole in the 90° side of the "T" for the coax connector. I used a BNC chassis mount on the first, and an SO-239 connector for the second Insta-Flex I built. The BNC is easier to install, but requires an adapter (Radio Shack™ 278-120) to connect it to coax using a PL-259-type connector.

Place one mark on the "T" where the driven element is to be located and one where the gamma rod is to be (see **Fig. 3**). Drill a small hole at the mark, all the way through the "T" where the driven element and the gamma rod will go; this will make an aligning hole. The gamma rod can be mounted either way—up or down.

The curved slot for the elements and gamma rod can be made any way you want (**Fig. 3**). The easiest way I have found is to trace the curve of the tape measure on the PVC, and then use a scroll saw to cut the curve.

Another method is to melt it through using a piece of the tape measure and a propane torch. The curved slot is very important for the rigidity of the elements. If you make a straight slot for

the elements, they will lose their ability to spring back into position, because the natural curve will be taken out of the tape measure. Place the piece of tape measure to be used to melt the slot directly over the small aligning hole. Make sure it is perpendicular to the "T" as shown in **Fig. 3**. Heat the piece of tape measure about one inch above the PVC, and when it is hot enough, it will melt the PVC. Light pressure will help force it through. Don't press too hard; the tape measure will bend very easily as the temperature increases. You will probably have to turn the "T" over and do the same thing on the other side. Make sure of the direction of the curve, as the element will have to go through both top and bottom curved slots. After the PVC cools, fit the element.

Make the curved slots for the reflector and director(s) the same way. Attach the SO-239 or BNC with a wire connected to the ground lug, long enough to reach the center of the driven element. Now install the driven element and the gamma rod, and secure them with hot glue or epoxy. Solder the wire from the ground lug to the center of the driven element (**Fig. 1** or **2**).

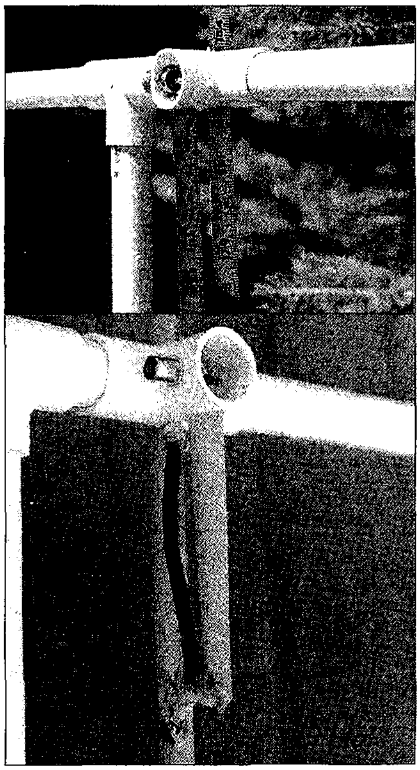

Photo A1, Photo A2. *Close-ups of gamma section.*

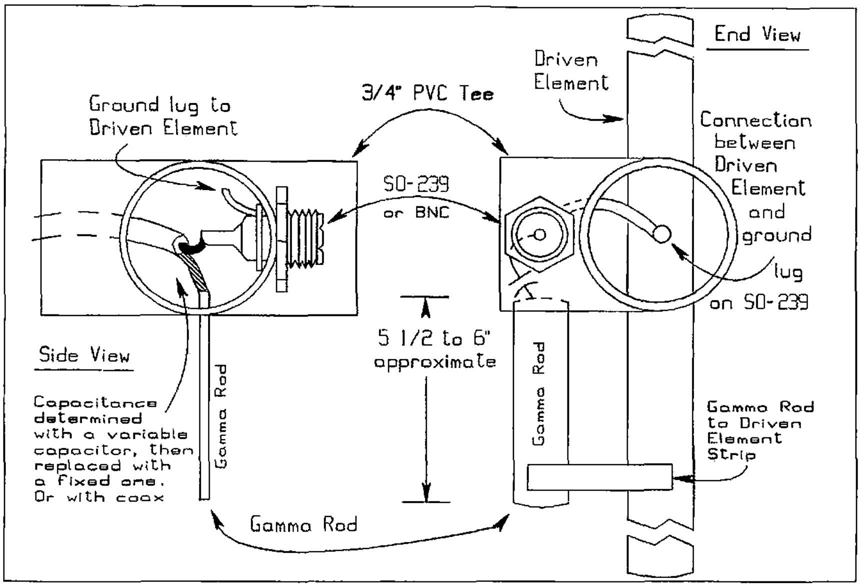

Fig. 2. *Tuning the Insta-Flex Yagi, method B.*

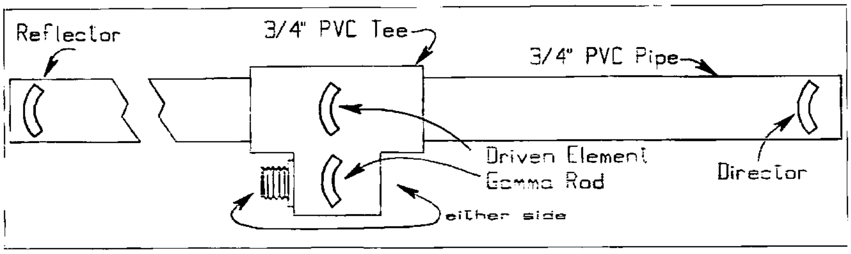

Fig. 3. Attaching the elements.

Use either method to complete the gamma match construction. Use a piece of coax to make the needed capacitance. If you use Method A, you may want to put a nonconductive support between the end of the gamma rod and the driven element.

Before securing the reflector and director(s), measure, cut and dry-fit the boom pieces into the "T"s. Once the proper spacing between elements is made, install the reflector and director(s) in the respective slots and secure them using hot glue or epoxy. Line all the elements up and press the boom pieces into the "T"s. You don't have to cement it together. If you do, make sure the elements and boom pieces are lined up *very* quickly; once the cement is set, you can't change it. I didn't cement mine and don't have a problem. If it comes loose, just line up the elements and press it together again.

Tuning

•Method A (**Fig. 1**): Connect the coax to the ends on the gamma rod and driven element as shown. Check SWRs and start trimming the coax off about 1/8" at a time. Check SWRs after each adjustment. After the lowest SWR reading is obtained, if it is not acceptable, try moving the attacking point on the gamma rod and driven element. You may need to trim a little off both ends of each element. It is better to cut the elements a little long and trim them than to have to replace them with longer ones. After the correct length of the coax capacitor is found, seal the open end with hot glue or epoxy. Make sure you leave the end *open*! Glue the coax capacitor to the side of the gamma rod. You might want to glue a piece of nonconducting material between the gamma rod and the driven element for added strength.

"Setup is instantaneous: Just pull it out of the tube and the elements will spring into position."

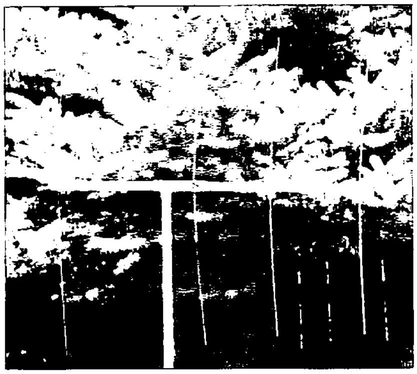

Photo B. The Insta-Flex in operation.

•Method B (**Fig. 2**): Use a variable capacitor (optional), and adjust for lowest SWRs. You may have to move the strip between the gamma rod and driven element up or down. After the correct capacitance is found, leave the variable capacitor in place, replace it with a fixed one, or use a coax capacitor. I've found it easier to replace the variable capacitor with coax and trim as needed. With both a three-element and a four-element, I have had better luck and faster tuning using the coax capacitor.

I have shown the Insta-Flex to lots of hams and have gotten lots of strange looks when they see what it's made of and how flexible it is. Try it—if you have comments, questions, or suggestions about improvements, I'd like to hear from you!

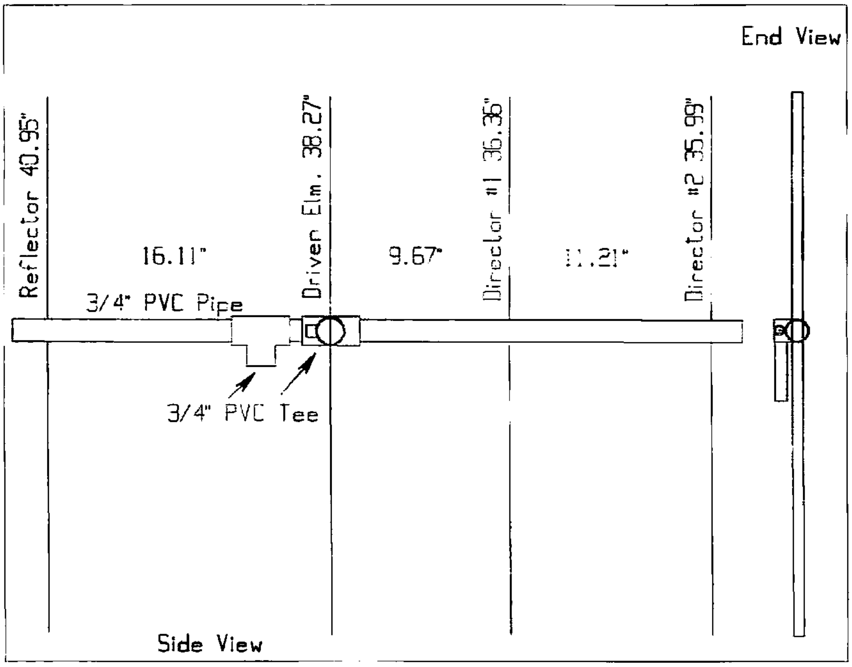

Fig. 4. Yagi for 3 or 4 elements.

Special Events

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the August issue, we should receive it by May 1. Provide a clear, concise summary of the essential details about your Special Event.

MAR 23

MADISON, OH The Lake County ARA will hold its 19th annual Hamfest 8 AM–2 PM at Madison H.S. on North Ridge Rd. The flea market will feature new and used amateur radio, computer and electronic equip. VE exams, forums, and an equipment test bench will be featured. Adm. $5 at the door. Table space $6 for 6 ft. table; $8 for 8 ft. table. Reservations for tables can be made by calling *Roxanne at (216) 256-0320.*

YONKERS, NY "WECAFEST 97" will be held 9 AM–2 PM at Yonkers Raceway, Central Ave. and Yonkers Ave. Pre-reg. of all vendors, including tailgaters, is recommended. Handicap accessible, door prizes, forums, food, more. Adm. $6. Call the WECA InfoLine at *(914) 741-6606, or write to Thomas Raffaelli WB2NHC or Jeanne Raffaelli N2NQY, 544 Manhattan Ave., Thornwood NY 10594.*

APR 4–5

ATLANTA, GA The Southeastern VHF Soc. of Cornelia GA will hold their 1997 conference at the Atlanta Marriott Northwest Windy Hill, located between Atlanta and Marietta GA (about 45 min. from Atlanta Hartsfield Internat'l Airport). Contact *Tad Danley K3TD* at *(770) 513-9252* or via *k3td@amsat.org.* The Web site is *www.akorn.net/~ae6e/svhfs.*

APR 6

OELOIT, IA The Denison Rptr. Assn. will host an amateur radio swap meet at the Deloit Community Bldg. in Deloit IA, 7 AM–2 PM. Adm. and tables $2. Talk-in will be on the KØCNM rptr. at 147.090. Reservations for table space may be sent to *Jim Currie KBØTLC,* or *Jim Slechta KAØHFR* at *Callbook* addresses. For more info, send E-mail to *John Amdor KD6MXL* at *johnmxi@netins.net.*

APR 10 AND 24

FT. WORTH, TX VE exams will be administered by the Lockheed ARC and the Kilocycle Club, 7 PM, at the Lockheed Rec. Area Facility, 2400 Bryant Irvin Rd. For details call *Ted Richard AB5QU, (817) 293-6745.* Some testing done by appointment only.

APR 11–12

TUPELO, MS The Tupelo ARC and Booneville ARC will co-sponsor the North Mississippi Hamfest and Computer Expo '97, Apr. 11th, 6 PM–9 PM; and Apr. 12th, 8 AM–5 PM. Location: The Mississippi Bldg. of the Tupelo Furniture Market Complex on Coley Rd. All-indoor hamfest/computer show, flea market, vendors, VE exams. Adm. $5, under 13 free when accompanied by an adult. Tables, $20. Contact *Jack Ellis KI5QV, Rt. 4, Box 198-B, Tupelo MS 38801. Tel. (601) 842-7255.* Talk-in on 147.38(+). Rag-chew on 147.24(+).

APR 12

FREDERICKSBURG, PA Northern Lebanon H.S. in Fredericksburg is the location for the 9th annual Hamfest and Computer Show being sponsored by the Appalachian AR Group. The event starts at 8 AM. General adm. $4, kids under 12 free. Indoor tables $14, tailgating $4. VE exams at 9 AM. Handicapped access. Morning seminars. Talk-in on 146.04/.64. Table reservations are recommended and must be prepaid. Tables not occupied by 9 AM are subject to resale. No refunds. Send check for reservations to *AARG, 105 Walnut St., Pine Grove PA 17963. Tel. (717) 345-3780.* Reservations may also be made with *Lanny Hoffman KD3TS, 337 N. 19th St., Lebanon PA 17046. Tel. (717) 274-2148.*

TRURO, NOVA SCOTIA, CANADA The Truro ARC will celebrate their 50th anniversary with a banquet at the Colchester Legion in Truro. Past and present members are invited to attend and celebrate. Reservations are required. A special QSL card has been issued for this historic event, and club members will operate with the special callsign prefix XK1 for the period Apr. 6th–19th. Contact *Dawn MacKay VE1MAK, 52 Spruce Dr., Truro NS B2N 4X6, Canada. Tel. (902) 893-3908,* or *E-mail dawn.mackay@nsac.ns.ca.*

APR 13

MADISON, WI The Madison Area Rptr. Assn. Inc. will hold its 25th annual Madison Swapfest at the Dane County Expo Center's new Exhibition Hall. Commercial exhibitors and vendors with 6 or more flea market tables will be admitted beginning at 3 AM; other flea market sellers will be admitted at 6 AM. Doors open to the public at 8 AM. New and used electronics gear. Talk-in on the M.A.R.A. rptr. W9HSY at 147.75/.15. Adm. $6 in advance, $7 at the door. Children under 10 admitted free. Flea market tables (2.5' x 6') are $15 in advance, plus adm. Reservation deadline is Apr. 5th. Contact *M.A.R.A., P.O. Box 8890, Madison WI 53708-8890. Tel. (608) 245-8890.*

RALEIGH, NC The Raleigh ARS will present its 25th Hamfest and Computer Fair in the Jim Graham Bldg., NCS Fairgrounds, 8 AM–4 PM. Wheelchair access. ARRL, MARS, ARES, NTS, QRP, and DX mtgs. Pre-reg. $5, $6 at the door. All inside. Tables and booths avail. Free parking. RVs welcome. Hospitality party Sat. night. VE exams, contact *AA4MY, (919) 847-8512.* For pre-reg. and dealer inquiries, contact *Ronnie Reams WA4MJF, 3509 Rolesville Rd., Wendell NC 27591. Tel. (919) 217-0263. Talk-in on 146.04/.64.*

APR 19

BELTON, TX A Ham Expo-Tailgate will be held at Bell County Expo Center starting at 7 AM. Adm. $1. Handicap access. Indoor tailgate spaces $10 at the door; setup begins at 6 AM. Vendor tables $20 ea. (reserve by Apr. 11th). Free elec. Commercial vendor Fri. eve. move-in surcharge, $10 per table. Sponsored by Temple ARC, 1802 S. 13th St., Temple TX 76504. Phone *Mike WA5EQQ, (817) 773-3590; E-mail: mlefan@vvm.com. Expo netpage—http://www.tarc.org.*

APR 20

CANFIELD, OH A giant outdoor flea market will be sponsored at the Canfield Fairgrounds, State Route 46 in Canfield OH, by the 20/9 Radio Club, Inc. Open 8 AM–3 PM. Free parking. Tickets $5 at the door. Inside tables $10 per 8 ft. Outdoor flea market free with admission. Talk-in on 145.275(-), 224.420(-), and 442.750(+). For more info, contact *Don Stoddard N8LNE, 42 S. Whitney Ave., Youngstown OH 44509. Tel. (330) 793-7072.*

APR 26

FLATWOODS, WV The 4th Annual Central WV Hamfest, sponsored by the Pioneer ARA, will be held 9 AM–3 PM at Braxton County H.S., I-79 Exit

67. Local motel available. Free parking. Dealers welcome. Tickets $5, flea market space $10 a table. First-come, first-served, unless reserved. Talk-in on 145.29 and 146.655. Contact *Ed Messenger N8OYY, (304) 462-5312;* or write to: *PARA/Hamfest, P.O. Box 301, Glenville WV 26351.*

HARMONY, NJ The 1997 Chenyville Hamfest will be held at Warren County Farmers Fairground on County Route 519 in Harmony. Open 8 AM–2 PM, setup at 6 AM. Adm. $6. Spouses and children under 12 free. Tables $20, indoor space includes electric. $10 outdoor tailgating space. VE exams $6.25. To pre-register and get details, call *Charlie Kosman WB2NOV at (908) 788-4080.*

SYRACUSE, NY "Spring Fest '97" will be held by the Liverpool Amateur Reptr. Club at the New York State Fairgrounds (Cattle Bldg.). The gate charge for anyone entering the bldg. is $5 per person. The bldg. will be open at 5 AM for vendors, 8 AM for tailgaters and the general public. Hamfest hours are 8 AM–2 PM. Vendors must exit by 5 PM. 8 ft frontage space $5 in advance, $10 at the door. Tables $7.50 ea. in advance, $10 ea. at the door. *Make payable to L.A.R.C.* and mail to *Tom Delasin WA2DAD, 4172A Burning Tree Rd., Liverpool NY 13090.*

APR 27

ARTHUR, IL The Moultrie AR Klub will hold their 35th Annual Hamfest at Moultrie/Douglas County Fairgrounds on the south side of Arthur, just off Route 133 behind the high school. Hours: 8 AM–1 PM. Adm. $4 per person over 14 yrs old. Tables $10 ea. in advance. No exams this year. Contact *M.A.R.K. P.O. Box 91, Lovington IL 61937;* or call for info *days, (217) 543-2178; eves., (217) 873-5287.* Talk-in on 146.055/.655 and 449.275/444.275.

FISHKILL, NY The ARRL Eastern New York Section Convention will be held at the Mt. Beacon Hamfest at John Jay H.S. in Fishkill. Ham radio, computer and electronics flea market. Adm. $5, spouses and kids free. Advance tables $8, $10 at the gate. Tailgating. Bring-your-own-table, $6 a spot. VE exams for all license classes. Talk-in on 146.97(-). Contact *Ken Akasofu KL7JCQ, 316 Titusville Rd., Apt. 4, Poughkeepsie NY 12603-2944. Tel. (914) 485-9617; Fax: (914) 485-2402. E-mail: Ken.Akasofu@bbs.mhv.net.*

MAY 3–4

ABILENE, TX The Key City ARC will sponsor the ARRL West Texas Section Convention and Hamfest at the Abilene Civic Center 8 AM–5 PM Sat., and 9 AM–2 PM Sun. Free parking. VE exams. Wheelchair access. Tables $6 ea. Pre-reg. $7 (must be received by Apr. 29th), $8 at the door. Talk-in on 146.160/.760. Contact *Peg Richard KA4UPA, 1442 Lakeside Dr., Abilene TX 79602. Tel. (915) 672-8889.*

MAY 4

HAGERSTOWN, MD The Antietam Radio Assn. will sponsor the Great Hagerstown Hamfest & Computer Show at Hagerstown Jr. College, Athletic, Rec., & Community Center. Setup Sat., May 3rd, 6 PM–9 PM, and May 4th, 6 AM–8 AM. Volunteers will be available to assist. All vendors responsible for collecting applicable state tax. Proper tax and license certificates should be made available upon request. Outside tailgating spaces $5 per space. Adm. $5, children under 12 free. Tables paid in advance are $15 ea. A discount is available for 11 or more tables. Limited free electric hookups. Contact *ARA, P.O. Box 52, Hagerstown MD 21741. Tel./Fax (301) 791-3010.* VE exams at 9 AM, at no charge, by the Mountain VEC. Walk-ins accepted. For testing info, contact *Leo Patterson KQ8E, (304) 289-3576,* or *Gay Rembold W3DFW, (301) 724-0674.* Talk-in on 146.940/.520 simplex on the day of the event and on the night before.

MAY 10

GREENVILLE, SC A hamfest will be sponsored by the Blue Ridge ARS, 8 AM-5 PM, at the Anderson County Fairgrounds, E of Anderson on Hwy. 29 Business. Flea market, Buck Rogers, K4ABT SEDAN packet conference, VE exams at noon, overnight camping, free parking. Talk-in on 146.01/.61. Advance adm. $4; $5 at the door. Contact *Gene WB4ZBZ,* or *David KE4QQQ, (864) 476-2609, E-mail: ke4qqq@innova.net.*

MAY 15–18

DAYTON, OH The "Four Days In May"™ QRP Symposium on Thursday, May 15th, held in conjunction with the Dayton hamvention©, will kick off QRP activities at Dayton. Full day of activities on Thursday at the Days Inn Dayton South (513-847-8422); includes multimedia QRP presentations, catered lunch, door prizes, tech talks, tutorials by clubs. Thursday registration $30 before May 1, $35 after (if still available). Make checks *payable to "Bob Follett" and send to: Bob Follett AB7ST, 2861 Estates Dr., Park City UT 84060, E-mail: bfollett@ditell.com.* On Fri., May 16th, the QRP-ARCI Awards Banquet will be hosted by FDIM Banquet Chairperson Pete Meier WK8S. Please send $15 banquet ticket fee (US check, MO, internat'l MO) *made out to "Pete Meier"* by May 1st. Mail to *Pete Meier WK8S, 4181 Rural, Waterford MI 48329;* or *E-mail pmeier@tir.com.* Also on the 16th, Preston Douglas WJ2V will host the FDIM QRP Vendor Evening Social. To register, contact *Preston Douglas WJ2V, QRP Vendor Evening Chairperson, 216 Harbor View N., Lawrence NY 11559,* or via *E-mail: pdouglas12@aol.com.*

MAY 16-18

DAYTON, OH The Dayton Hamvention©, sponsored by the Dayton ARA, Inc., will be held at the Hara Arena. Fri., May 16th: Flea market open and bus service avail., 8 AM–6 PM; exhibits, noon–6 PM; forums 1 PM–5 PM. Sat., May 16th: flea market and bus service 7 AM–5 PM; exhibits 8 AM–5 PM; forums, VE exams, activities, 9 AM–5 PM; hamvention banquet at the downtown Dayton Convention Center, 6 PM. Sun., May 17th: flea market 7 AM–4 PM; bus service available 7 AM–5 PM; exhibits open 8 AM–2 PM; forums and activities 9:30 AM–1:30 PM; prize drawings 2 PM. Programs available Fri. at 7 AM in the Hara Arena lobby and in the tent in front of the East Hall entrance. Flea market spaces are sold in advance only; a maximum of 3 spaces per person (non-transferable). Limited to amateur radio, electronic, and related items only. Electricity available in a portion of the last flea market row for $60 a space extra. Tables and chairs not available. Contact the *Flea Market Chairman by FAX at (937) 253-1289, by E-mail at fleamkt@hamvention.org,* or by *voice mail at (937) 276-6932;* allow 30 seconds for the phone routing system to transfer the call. Registration tickets in advance $13, at the door $15. Banquet tickets in advance, $25; after May 17th, if available, $30. Flea market spaces $50/1 space, $110/2 adjacent, $220/3 adjacent; elec. $60 extra each space. Covered tent w/elec. $325 ea.

SPECIAL EVENT STATIONS

APR 18–20

CHARLOTTESVILLE, VA The Albemarle ARC will operate station WA4TFZ, 2300Z Apr. 18th–2300Z Apr. 20th, to commemorate the Charlottesville Dogwood Festival. Operation will be in the General portion of the 80, 40, and 20 meter bands, and the Novice portion of the 10 meter band. For QSL, send QSL and SASE to *Bill Bearden KC4TQF, 237 Falling Rock Dr., Stuarts Draft VA 24477 USA.*

APR 25–26

THOMASVILLE, GA The Thomasville ARC will operate W4UCJ 1700Z–2300Z Apr. 25th and 1100Z–2000Z Apr. 26th, to commemorate the 76th Annual Rose Festival. Operation will be in the lower portion of the General 80, 40, 20 and 15 meter phone subbands, and the Novice 10 meter phone subband. For a certificate, send QSL and a 9" x 12" SASE to *TARC/Rose Festival Station, P.O. Box 251, Thomasville GA 31799 USA.*

MAY 3–4

DANBURY, CT The 1997 Connecticut QSO Party will be sponsored by the Candlewood ARA, 2000Z May 3rd–2000Z May 4th, with a rest period 0400Z–1200Z. Phone, RTTY and CW. For operating rules, contact *CARA, P.O. Box 3441, Danbury CT 06813-3441 USA.* Please remember to send an SASE.

PHILADELPHIA, PA The Olympia ARC will operate WA3BAT from 1300Z May 3rd–2000Z May 4th, to commemorate the 99th anniversary of Admiral Dewey's triumph over the Spanish fleet at the Battle of Manila Bay. SSB/Phone: 3.898.5, 7.248.5, 14.248.5, 21.368.5, 28.368.5, 145.270 FM. CW: 3.710, 7.030/.110, 14.030, 21.040/.110, 28.025. For a certificate, send QSL and a 9" x 12" SASE to *Olympia ARC, Independence Seaport of Philadelphia, 211 South Columbus Blvd., Philadelphia PA 19106 USA.* 73

Free test signals

From Phil Salas AD5X: "Those little MFJ SWR analyzers also make great little portable signal generators for general testing purposes. In order to do their job as SWR analyzers, the units need to simulate a very low power CW transmitter, along with an equally sensitive SWR metering circuit. You can therefore use these little gems for general signal injecting or troubleshooting, as well as for antenna and transmission line analysis.

"In order to achieve a variable RF signal output, I've used a Radio Shack™ #15-578 variable 75-ohm TV attenuator, along with the appropriate adapters, to reduce the signal level to whatever I've needed for the particular troubleshooting job at hand. I also decided to open up the Radio Shack attenuator's case and replace the F-connectors with BNC connectors. Just another twist to make the attenuator even handier! And speaking of Radio Shack, I've found that their #21-506 50-ohm dummy load can be expected to work well up to about 500 MHz. It will handle 10 watts continuously, or even 100 watts for a few seconds at a time. I've put 100 watts into mine a number of times, getting it so hot that I couldn't touch it, and it doesn't seem to have damaged or degraded the unit's SWR in the least. Try not to overdo it, though!"

Hard-to-find variable caps

From John Nix: "If you find yourself in need of a fairly large, fairly expensive variable capacitor for that low frequency antenna tuner project you've been putting off, here's an idea you might want to consider adapting to your own requirements.

"Just as an example, let's assume you're looking for a 1,000+ pF variable cap... not the easiest thing to come by... but don't let that stop you. Variable caps in the 365 to 420 pF range are fairly common, so all you really need to do is to switch in additional 350 pF (or so) good quality (meaning stable) fixed capacitors, ones that will put you in the right range, until you have the value over the maximum value of your variable cap on hand. In other words, if you need a maximum of 700 pF, use a 365 pF variable and a 350 pF fixed cap in parallel... this will give you something in the area of a 380 to 715 pF variable. If you'd like to get up to a 1,000+ pF variable as mentioned before, use a 365 pF variable along with two paralleled 350 pF fixed capacitors, for a total of 730 to 1,065 pF variable. **Fig. 1** shows how to do this using just a two-pole, three-position rotary switch. Of course, you can substitute whatever actual values you wish for the various capacitors, and add more fixed 'jumps' by using a rotary switch with additional poles and additional positions; another pole and another click-stop position are needed for each fixed capacitor 'jump' above that shown in **Fig. 1**. It's worth keeping in mind for future use, even if you don't have an immediate need right now... it can save you some money that might have otherwise been spent on high-priced, hard-to-find high-picofarad variable caps!"

> ***"This sounds like it might be an excellent opportunity for a budding machinist/entrepreneur..."***

Hot stuff!

From Richard Measures AG6K: "The explanation that follows will help you to understand why the electrolytic filter capacitors in the popular Heath SB-220 linear amplifier, and others of similar design, are subjected to a higher-than-healthy degree of heat during 'normal' operation. The SB-220 is typical of many linears in ham shacks around the world, so these tips may well find applicability in yours, regardless of its actual brand-name and model number.

"A major source of heat applied to the electrolytic filter capacitors in the SB-220 is from the eight 30k, 7-watt voltage-equalizing resistors that are directly adjacent to the eight electrolytic filter capacitors used in the high-voltage power supply. A minor source of capacitor heating results from a 60 Hz ripple current flowing through each capacitor's inevitable internal resistance. In the SB-220, the filter capacitor heating problem is compounded by the fact that air cooling from the amplifier's fan doesn't directly reach the capacitors' metal cans... this is because the molded plastic covers that surround and insulate each electrolytic also act as thermal barriers. Some amplifiers use paper slip-on covers, but all use some form of insulating medium because of the high voltage on the metal cans themselves (since they're above ground in almost all cases). In the SB-220, I've seen this plastic insulating material actually melt in the areas nearest the eight 30k, 7-watt resistors! One can only imagine what the temperature inside the cap must be! It's worth mentioning that wet electrolytic capacitors will have their life expectancy reduced by a predictable amount for every degree rise over normal room temperature (70 degrees F). Many electrolytics are also marked as having a maximum permissible operating temperature... a temperature that should never be exceeded under any circumstances. By the way, that doesn't mean that the capacitor can be operated near that maximum without lifeexpectancy degradation, as mentioned before.

"It's interesting to note that the heat produced by these eight 30k resistors can be reduced by 570% simply by changing them to 100k, 2- or 3-watt metal-oxide-film resistors instead. This modification alone should greatly prolong the expected life of the eight filter capacitors in an amplifier like the SB-220. Other resistance values may be used, up to about 150k, provided the resistors themselves can withstand the voltage across them. Metal-oxide-film resistors of the 2- to 3-watt variety are

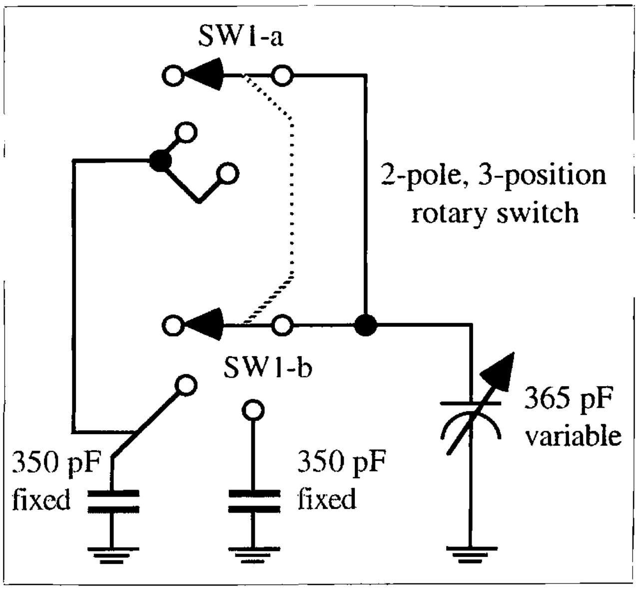

Fig. 1. Paralleled fixed capacitors, added to a variable capacitor via a rotary switch, will provide an (apparent) increased maximum value for the variable—see text.

often only rated at 350 volts maximum across the element, but this can easily be doubled by using two 50k resistors in series (in place of one 100k unit). Spiral-film resistors, if available, can also be used, since they'll withstand higher voltages across them than any other variety of resistor. By the way, I don't recommend using the older carbon composition types: they don't maintain their tolerances well with heat and age.

"Increasing the value of the equalizing resistors across the filter capacitors will also increase the 'bleed-down time' of the capacitors when the power is turned off. Therefore, be especially careful to allow enough time for the charge on the caps to bleed off by watching the voltmeter on your amplifier drop to zero. Then apply a reliable jumper lead from the HV anode terminal directly to ground to provide a sure ground path for the high tension point.

"Here's another caveat about something that can occur in some linears with an automatic shorting interlock switch, such as the Heath SB-220: It will spill the HV filter caps' charge directly into the grid-current metering shunt when a short is applied by the interlock switch action or by an external jumper to ground, if the charge on the caps has not been allowed to bleed off normally. If the meter happens to be in the grid-current position when this happens, it can be destroyed in short order under these conditions! So just opening the HV compartment can potentially (no pun) fry your amplifier's metering circuit—something you wouldn't normally think of unless you've seen it happen. That's another good reason not to leave the multimeter switch in the grid-current position and to not even go into your linear until the caps have had a reasonable time to bleed off their high voltage charge. So again, put the meter in the high voltage voltmeter position and keep an eye on it until it's safe to enter."

Moderator's note: One source for the metal-oxide-film resistors mentioned in Rich's piece is Digi-Key Corporation, 1 (800) 344-4539. As an individual, Rich has done an amazing amount of research into amateur HF amplifiers, their peculiarities and their shortcomings. I've found his "fixes" to be practical, and his procedural outlines should be manageable by the average ham radio hobbyist. As Rich said, please remember that anytime you're working around high voltage components you should take time to think about the safety procedures that must be followed. We tend to become somewhat complacent since most of our servicing is done on low voltage electronics these days, but the high voltage present in tube equipment is just as deadly as it ever was—maybe more so because of our current tendency toward complacency. I know that I have to keep reminding myself to go slowly and cautiously when tube anode potentials are nearby.

Easy in and easy out

From Mark Marholin KE6JJR: "For TS-50S and IC-706 (and probably most other rigs) mobile users, the standard screws used to attach the radios to their mobile mounts are 4mm x 20mm Phillips-head screws. This makes removal of your radio from your mobile mount inconvenient and time-consuming. Sometimes getting even a 'stubby' Phillips screwdriver alongside the radio's mounting bracket can be challenging.

"For a major improvement in this area, purchase 4mm x 20mm steel hex head screws and #4 thumbscrews from your local hardware store or home center. Cut off all but three or four threads on the threaded portion of each of the thumbscrews and screw them into the hex head of the 4mm x 20mm screws. This will be simply a friction fit, but it will hold the thumbscrew part to the hex head screw part temporarily. Now solder the thumbscrew part to the hex head part with silver solder, acid flux (not rosin flux) and plenty of heat. Clean the screws well when cool to remove all traces of the acid flux. Now you have 4mm x 20mm thumbscrews that make it a snap to install and remove your mobile rig from its mobile mount by hand."

Moderator's note: This sounds like it might be an excellent opportunity for a budding machinist/entrepreneur—supplying metric thumbscrews for a variety of uses in the amateur radio market. These are the types of recognizable business opportunities that Uncle Wayne has spoken of so often in his editorials. There are many such "gateways of opportunity," supplying simple but necessary

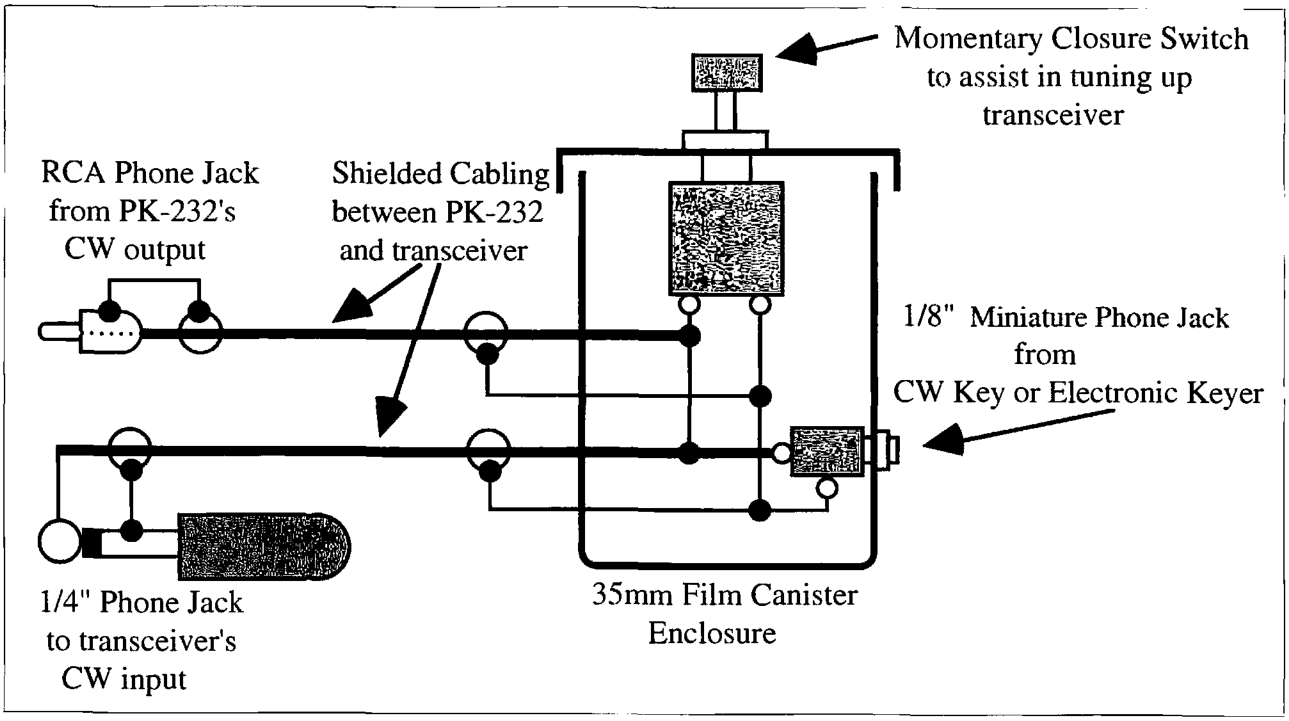

Fig. 2. AD1B's "Tune-up Assistant." See text for full details.

accessories to the amateur marketplace. They can sometimes lead to eventual independence from the need to get up every day and trudge off to the same job at someone else's place of business.

Photo opportunity

From Thomas Hart AD1B: "Being active on all bands from 160 through 2 meters, on a variety of modes, I decided to add a PK-232 terminal unit to my station to augment CW as well as the various digital modes of operation. Since converting over, I've found myself using my straight key and keyer very infrequently, relying instead on my computer and terminal node controller (TNC) for virtually all non-voice communications.

"For those times when I need to manually key the transmitter (for adjusting power output and for antenna tune-up), I've found this simple device (shown in **Fig. 2**) to be more than adequate. Basically, it consists of a discarded 35mm film canister, holding a momentary push-button switch, that can be used to key my transmitter, allowing me to make final adjustments to the transceiver/transmatch combination. There's also a miniature female 1/8" phone jack in the side of the canister for inserting a straight key, bug, or electronic keyer if desired... just for nostalgia.

"The few parts needed are readily available from any Radio Shack store and the layout is noncritical, quick and easy. Simply cut the line that presently connects your TNC to your rig's keying input and insert the circuit shown in Fig. 2 in parallel with that line. The entire project should take only a few minutes to complete... not counting the time needed to go to the store to buy the roll of film! The converted film canister stands on the shelf next to my Kenwood transceiver and has been very useful for my own operating setup. I hope that some variation on it will work for you just as well."

More small bulbs

From Andrew Gretchenuk: "A good replacement bulb for meters and dials in modern transceivers can be found in the type 2182 miniature lamp. The 2182 is rated at 14 volts at 80 milliamperes and has an average bulb life of 40,000 hours (that equates out to nearly five years of constant running!). If operated at somewhat less than 14 volts, the life expectancy will naturally increase. For instance, when operated at 12 volts, the 2182 lamp draws 75 milliamperes and will probably last 20 to 25% longer yet. Long life for our transceiver's bulbs is important, especially if the equipment is left running 24 hours a day, as in the case of most packet BBSs, digipeaters, and network nodes. The 2182 lamp measures about 3/16" in diameter and 7/16" long and comes with sufficiently long wire leads. It would be a good replacement choice for spots where that physical size doesn't preclude its use. Check out the Mouser catalog (tel. 800-992-9943; http://www.mouser.com) as one source for this lamp and keep a few of these bulbs on hand."

More TV

Last time, we examined the history and basic theory behind scanning a television image. Let's continue, this time looking at color and the makeup of the video signal.

The magic rainbow

As soon as fully electronic television began to take off in the marketplace—perhaps even before then—work began on adapting it for color. Borrowing from the old scanning disk concept, CBS created a color TV system that was a hybrid of the old and the new. It used a picture tube to create a monochrome image, with a rotating disk in front of it. This disk didn't scan the image, though. Instead, it was broken up into three sections, each consisting of a color filter for each of the additive primary colors: red, green and blue. The disk was automatically synchronized to the vertical scan rate of the incoming signal, resulting in the successive display of three pictures, one in each color. The human eye, which cannot sense color changes very fast, integrated all three pictures into one full-color image. It worked, but it had limited brightness, due to the light loss through the filters, and there was some flicker. And, just like with the old mechanical scanning system, it took a big disk for the size of the resulting picture to be acceptable.

Ultimately, an all-electronic system created by RCA engineers won out, just as all-electronic television itself had displaced mechanical scanning. But how the heck do you create colors on the face of a tube?

Rare earths

Just as the phosphors in monochrome picture tubes could be made to give off white light (well, OK, bluish-white), it was found that various minerals called "rare earths" would generate different colors when struck by an electron beam. With careful selection, it was possible to create red, green and blue phosphors. The trick now was to scan three separate images, with three separate beams, in one picture tube. How could you do that?

Playing the angles

The answer was simple geometry, combined with some high-precision manufacturing. The colored phosphor dots were deposited on the inside face of the picture tube in a repeating pattern, each group of three next to another. For many years, that pattern was a tiny triangle composed of round dots. Then, in the 1960s, the Sony Corporation invented and introduced their Trinitron™ tube, which put the three colors in stripes, one color next to the other. This resulted in more of the beams hitting the phosphors instead of the space between them (because there was less space wasted), and thus much higher brightness—it gave the company's TVs a tremendous advantage. The basic Trinitron patent has long since expired, and virtually all current sets are made with striped tubes.

A quick detour

By the way, if you're thinking that having the colors next to each other, no matter what the configuration, would produce three images that didn't quite overlap perfectly, you're absolutely right! Luckily, the human eye's ability to distinguish color changes over small distances is very limited. The result is that the eye blurs the three pictures into one full-color image. Heaven only knows what a color TV picture looks like to an eagle. Probably nothing very good. If you want to see what the picture is really made of, get right up to the face of the tube and take a look—you'll plainly see the red, green and blue stripes. The only TV sets that actually overlap color are projection sets with separate projection tubes, one for each of the three colors.

Back to our story

So, you now had the necessary elements to paint three pictures. But, how to scan the three images? At the back of the tube, in the neck, were separate "electron guns," which were just like the ones in a monochrome tube, except that there were three of them next to each other. Behind the layer of phosphors on the tube's face, a metal grille with very fine holes, called the "shadow mask," was placed. The angle of the holes permitted only the beam coming from the requisite gun to enter, so the beam for the green image could only light up green phosphors, and so on. Now, it really was possible to paint three colors at the same time, all independently. But from where was the color signal to come?

Sooo-eeee!

Talk about a bandwidth hog! It was possible to simply transmit three complete TV signals, use three tuners at the set, and be done with it. Possible, yes. Practical, no. First of all, such a scheme would require using up three times the spectrum space of a monochrome signal. Second, it would require three times the transmitter power. Third, three tuners in each set would be mighty expensive. Finally, doing it that way would make the signals incompatible with the millions of existing monochrome sets. Why? Because the mono set would only be seeing a picture whose brightness values corresponded to one color out of three. It would be recognizable, but it would sure look weird.

Another approach

There had to be another way, and there was! Inventing it meant thinking of a color picture in a completely different way: as two separate elements. One was the brightness of each dot on the screen, which was exactly the same as with any monochrome picture. The second was the color value of that dot, which itself consisted of two more elements: hue (such as red, orange, etc.) and saturation (how strong the color was).

The advantage of treating the picture that way, instead of as three separate images, was tremendous. Now it was reasonable to consider sending the image in about the same bandwidth as a monochrome picture. Remember when I said that the eye can't discern fine spatial details of color? Well, that meant you didn't need to send very detailed color information, so the color (or "chroma") signal didn't require a lot of bandwidth, as long as the brightness (or "luminance") bandwidth was high.

Piggyback

But where, oh where, could you put the chroma signal? The answer lay in a bit of spectral cleverness. Television, being a repeating phenomenon—each line repeats at the same rate, no matter what's in the picture—had most of its spectral energy in repeating clumps of frequencies, with very little energy in between them. It was decided that a subcarrier signal (a carrier riding on the luminance signal) could carry the color information. By carefully choosing the frequency of the subcarrier so that it didn't divide evenly into the line rate, the spectral holes could be filled with the color signal. In theory, the two wouldn't interfere with each other!

In theory. In practice, if a signal is there, it's there, and you'll see it. Due to the deliberate nouharmonic nature of the chroma vs. line rate frequencies, the real effect was that each line of video had most of the chroma peaks and valleys in different places, and each frame had them opposite to the last one. The result was that the color signal appeared as a slight herringbone pattern, hard to see because it tended to average out over two frames. If you want to see what it looks like, get a black-and-white TV with a manually adjustable tuner, and turn the fine-tuning control in the direction of maximum picture sharpness (usually clockwise). Keep turning it a little more, and you'll see the herringbone pattern. You may also see squiggly lines that move with the audio portion of the broadcast, because another subcarrier carries the sound, using FM.

Exactly how the color information for the entire visual spectrum is encoded onto one subcarrier is a fascinating topic, and we'll explore it next time. Until then, 73 de KB1UM.

HAMS WITH CLASS

Visiting local schools

It's always nice learning about what hams are doing throughout the country to help promote amateur radio to young people. It's important to share ideas with each other so we can all benefit from the successes we've been fortunate enough to achieve. My friend Bob Raffaele W2XM from Albany, New York, has always been interested in getting children involved with the hobby. He recently sent me the following article he wrote in hope that readers of this column would get some ideas that they could use in their local schools.

Bob writes: "Most of us get so much satisfaction from ham radio that we want to share it with those who are not yet involved. For those who want to make a presentation to school-aged kids, I hope this encourages you. School kids are curious and quick to learn. However, there are obstacles. In general, kids are more than a little impatient and undoubtedly hard to impress. I've dealt mostly with 6th graders. They know about cellular phones and the World Wide Web; they will not be awed by a demonstration of your HT and a description of the DX you can work from home.

"Hams communicate via keyboard and CRT, voice, telegraphy, and television. They talk with astronauts, DXpeditioners, and fellow hobbyists of all ages. Hams are pioneers in communications technology; they assist in emergencies; and many have rigs, and HF or packet stations, right in their cars. To help children to appreciate our world of amateur radio, we'd like to teach them about all these things... and more.

"In our enthusiasm, however, we sometimes have a tendency to cause kids to expect more than we can deliver at the moment. Let's not build up their expectations, only to let them down. There is no sadder sight than a classroom full of disappointed middle-schoolers. Playing it safe, this presenter uses 40 SSB, 15 SSB, and 2m FM for most live demonstrations. On-the-air QSOs are only a small part of a comprehensive lesson on ham radio.

"Nathaniel KB2HPX and I have planned a presentation that fills two to three hours on each of two days. I've adapted this lesson for 6th graders because at this grade level they know enough geography and math skills to benefit from the interactive learning."

Bob goes on to explain that since he and Nathaniel teamed up to do their presentations in local schools in 1992, they've been very well received. But recently the demand for them in the classroom has decreased. They seem to have met up with what many of us in the classroom are starting to encounter... the inevitable comparison to the very popular Internet.

We who are concerned about the recruitment of young people into ham radio need to be ready to change our old motivation techniques when they really don't work like they used to.

Bob continues: "On-line access to information and pictures, and the ability to transfer large quantities of data quickly and reliably, are aspects of communications where the Internet beats amateur radio hands down (as long as electrical power and telephone service are available and uninterrupted). The Internet is an appliance; many people use it, but few understand it. Ham radio is a communications service and an educational hobby that can be so totally engrossing it can easily become a 'way of life.'

"Perhaps an environment in which both newcomers and veterans are being enriched and in which technology is being advanced should be called a very successful educational institution, and not just a 'hobby.'

"Here's a lesson that works well in a classroom and includes operating a low-band rig. Forty meters and 15 meters are the bands of choice. The antenna is a 40m dipole, modified to enhance dual-band operation.

"With hand-held rigs, small antennas, repeaters allowing distant contacts, autopatches, and local hams standing by to encourage the kids, a 2-meter contact can be great. Our VHF antenna is a vertically-mounted coaxial dipole that is placed outside. The antennas should be installed and tested before the demonstration.

"Kids will be intrigued to find you talking on the air as they enter the classroom that day. Using this 'teaser' as an introduction is a good idea only if the demonstrator is not performing solo. Someone has to explain what is happening.

"It is explained that the only things required for the exchange of voices are invisible radio waves and devices to emit and capture them. A display of antennas can be set up so the students can see that ham antennas need not be expensive or large and cumbersome.

"Students can calculate the lengths of the antennas with the help of formulae that you provide. You can teach the meaning of 'frequency' as being a 'location on the dial.' Once 'frequency' is in their vocabulary, the kids are ready for some algebra and division: Let the math begin!"

W2XM has learned to work with the teacher to include amateur radio in other curriculum areas. Any reader who wants lesson plans to use in different subject areas can write to this "Hams With Class" column or to Bob Raffaele at E-mail: bobw2xm @tu.albany.ny.us.

Bob and Nathaniel have learned to use QSL cards and the "Archie" comic book published by the ARRL in their presentation. They seem to have mastered the importance of doing lively demonstrations, keeping the pace fast, and having lots of visual materials for the children.

Bob has so many good ideas to share about his experiences in the classroom. We wish him continued success as he continues to persevere in trying to reach youngsters in local schools.

California balloonin'

During a recent visit with Mike Henkoski KC6CCC in San Clemente, California, I had the opportunity to participate in a unique experiment. Mike had designed an FM ATV transmitter and amplifier for the 2 GHz band. Now he wanted to use a high altitude balloon flight to test out the range of his 1-watt transmitter in combination with his latest ground station configuration. Back in November he had flown just such a transmitter onboard a rocket that sent it up to 53 miles high above the Black Rock Desert in Nevada with phenomenal results (watch future columns for the story).

The payload

Mike's payload was a very lightweight Styrofoam™ package (2 pounds total) consisting of a small exciter board on 2.442 GHz, a 1-watt amplifier, a homebrew circular patch antenna on the bottom of the package and a color TV camera (Computar pinhole). Four D-size lithium cells [made by SAFT, available from Avex Electronics (800) 345-1295] provided power for the system to give him nearly seven hours of operating time. *Note: The 2 GHz transmitter and amplifier are products designed for commercial surveillance and retuned for the amateur band. For more information on these products, check out their Web site at: http://microtekelectronics.com.*

"As the wind gusted, Lisa nearly went for a ride!"

The ground station

The receive setup consisted of a 60-inch satellite dish originally designed for the Ku band [KTI brand with an F/D of 0.41, available from Skyvision (800) 543-3025]. Mike mounted a Microtek 2 GHz receiver board on the dish along with a Tecom dual-patch circularly-polarized antenna located in its focal point, designed to slightly underilluminate it.

Photo B. Lisa Taylor prepares to launch the balloon from a park near San Clemente.

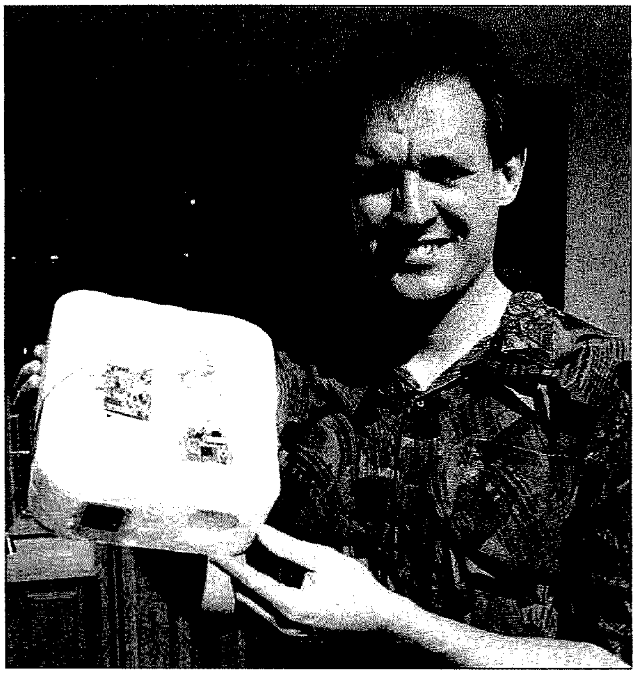

***Photo A.** (All photos by Bill Brown WB8ELK.) Mike Henkoski KC6CCC holds the 2 GHz ATV payload. The exciter board, color camera and patch antenna can be seen.*

The flight

February 1st turned out to be a typical sunny California day just perfect for launching a balloon. Mike KC6CCC, Duane Snipes WB6GGF, Bill WB8ELK and Lisa Taylor set out for a park just east of Mike's house to set up the ground station. In addition to the 60-inch dish sitting next to Mike's truck, we were able to link the launch (as well as the received downlink from the balloon during the flight) to the KC6CCC ATV repeater on top of Santiago Peak. This unique all-microwave repeater operates with an input on 10.4 GHz and an output on 3.480 GHz and will be a subject for a future column. Mike linked the launch activities up to the repeater via a special link receiver on 2.418 GHz. To cover the majority of ATVers in the region, one of the local ATVers took the output of Mike's repeater and retransmitted it out via the WA6SVT ATV repeater (also located on Santiago Peak with a 434 input and 1253.25 output). The flight coverage would involve two ATV repeaters and four frequency bands!

As Mike and Duane set up the ground station and tested the links to the ATV repeaters, Jim Porep KC6TFV and Curt Toumanian N6TWB (our chase crew) arrived on the scene. We started the balloon inflation and final checkout of the payload. Just before liftoff, Lisa (holding the balloon) nearly went for a ride herself as a couple of wind gusts kicked up. Fortunately, things quieted down and the balloon took off nicely without her.

Photo C. (l to r): Mike KC6CCC adjusts the receive dish while Duane WB6GGF and Lisa watch the downlinked video.

Although the package was spinning around quite a bit (Dramamine will be in our travel kit next time), the transmissions from the balloon were snow-free most of the time and in beautiful color. As the balloon gained altitude, we could see the California coastline from San Diego to Malibu, as well as several islands, including Catalina. Just before the balloon burst at an altitude of around 95,000 feet, we could clearly see the blackness of space and the curvature of the Earth. We could see a large portion of southern California extending from Malibu all the way to the Salton Sea. Even though the payload was well over 50 miles away, the reception was still snow-free a good deal of the time, with some deep fades. Although the large dish had a narrow beamwidth, it was possible to bring in a great picture most of the time.

When the balloon burst, we could see the package flip over and saw bits of the balloon fly past the camera. The parachute descent was smooth and we were all amazed at just how low on the horizon we could still see decent video. Apparently the signal was "knife-edging" over a nearby range of mountains, and we could see a snowcapped mountain and a small town below the payload just before it landed.

Using cross-bearings from the launch site, Mike WA6SVT's QTH, and the chase crew, we determined that the payload had landed in a particularly rugged area just east of Santa Rosa Mountain, about 10 miles south of the town of Anza. Unfortunately, it has not been recovered as of this writing.

Although the payload was lost, the flight was certainly a successful demonstration of the capabilities of microwave FM TV.

Photo D. (l to r): Jim KC6TFV and Curt N6TWB prepare to chase the payload with their mobile 2 GHz ATV receive station.

QRP

Number 60 on your Feedback card

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

April showers bring May flowers, but they also bring the Dayton Hamvention®! This year, the QRP forums will be larger than ever. Last year, we completely filled the banquet room on Saturday night!

Here's this year's information directly from the source, Bob Gobrick VO1DRB/WA6ERB, FDIM Publicity Chairperson:

Four Days In May QRP Symposium—the amateur radio QRP event of 1997

The QRP Amateur Radio Club, International (QRP-ARCI) proudly announces the second annual Four Days In May QRP Symposium to be held on Thursday, May 15, 1997—the first of the four festive days of 1997 Dayton hamvention QRP activities. Mark your calendar for this extra bonus day and register early for this not-to-be-missed QRP event of the year.

Amateur radio QRP presentations, workshops and demonstrations will be the focus of the full-day Thursday activities to be held at the Days Inn Dayton South (513-847-8422). Last year, this sold-out event had a "standing-room-only" crowd of 100 enthusiastic pre-registered attendees. For 1997, the FDIM QRP Symposium will be moved to the hotel's larger ballroom facility, so make your reservations early before it is sold out again. FDIM QRP Symposium attendees will start their day with a wake-up coffee social and then plunge into a morning of multimedia QRP presentations by renowned QRP authors and designers. At midday, attendees are treated to a catered lunch and QRP door prizes. Then it is back to an afternoon of exciting QRP technical presentations. Topping off this first day will be an evening of guest QRP tutorials sponsored by regional QRP clubs. The 1997 Four Days In May QRP Symposium will be the talk of the 1997 Dayton hamvention.

The Four Days in May QRP extravaganza then continues with the annual Friday night QRP-ARCI Awards Banquet honoring QRP dignitaries for their service to the amateur radio community. Following the awards banquet, a special evening has been set aside for the FDIM QRP Vendor Social where prizes will be drawn. Saturday will also be special this year with an evening for QRPers to meet the many regional North American and international QRP clubs—bring your banners! QRP Club awards will be presented to those who submit their pride-and-joy QRP construction projects for judging.

> **"Last year, this sold-out event had a 'standing-room-only' crowd of 100 enthusiastic QRPers."**

Four Days In May QRP Symposium: frequently asked questions

• QRP Symposium Presenters—Please submit your QRP technical manuscripts to FDIM Technical Paper Chairperson Bruce Muscolino W6TOY/3 at P.O. Box 9333, Silver Spring MD 20916-9333; E-mail: w6toy@erols.com. Presenters' papers will be bound into the 1997 FDIM QRP Symposium *Proceedings*. All attendees receive the *Proceedings*.

• FDIM QRP Symposium Registration Fee—Registration for the Thursday, May 15, 1997, FDIM QRP Symposium will be $30 if prepaid by May 1, 1997, and $35 after that date or at the door. At the door, registration may be limited if we once again sell out. Please register early to guarantee a seat. Registration will cover a full day of QRP Symposium activities, which include the QRP technical presentations, the 1997 FDIM QRP Symposium *Proceedings*, the scrumptious QRP luncheon, those famous "special" Symposium bag stuffers and, finally, an endless QRO coffeepot.

Please send your $30 registration fee (US check, money order, or international money order) made out to "Bob Follett" by May 1, 1997, to: Bob Follett AB7ST, FDIM Registration Chairperson, 2861 Estates Dr., Park City UT 84060. E-mail: bfollett@ditell.com.

• QRP-ARCI Awards Banquet—This not-to-be-missed Friday, May 16, 1997, event is once again being hosted by FDIM Banquet Chairperson Pete Meier WK8S. Please send your $15 banquet ticket fee (US check, money order, international money order) made out to "Pete Meier" by May 1, 1997, to: Pete Meier WK8S, 4181 Rural, Waterford MI 48329. E-mail: pmeier@tir.com.

• FDIM QRP Vendor Social—A tradition was started at FDIM 1996—a special evening was established to officially introduce our QRP vendors from around the world. All are invited to attend this wonderful Friday, May 16, 1997, evening social. Preston Douglas WJ2V will once again be our gracious host. QRP vendors: For registration information, please contact Preston Douglas WJ2V, QRP Vendor Evening Chairperson, 216 Harbor View N., Lawrence NY 11559. E-mail: pdouglas12@aol.com.

Bob Gobrick concludes: "On behalf of the entire FDIM team, I invite you all to join us for the QRP event of 1997—the Four Days In May QRP Symposium at the 1997 Dayton hamvention. Questions? My E-mail is 70466.1405@compuserve.com. See you all there!"

So there you have it—all the information you need to join us next month. I highly recommend the Four Days in May for all QRP operators. And don't forget: While you are enjoying the Four Days in May, your wife can be off happily shopping at the Dayton Mall. It's within walking distance of Days Inn South!

Rooms for Dayton

As in the past, Myron is handling the rooms for the hamvention. You can contact Myron at (330) 477-5717 to inquire about the status of open rooms. There is usually a waiting list, so don't wait too long.

QRP-ARCI dues

One more time, just in case you missed it: The cost of joining the QRP-ARCI is $17 for US hams. To renew your membership, the price is $15 for US hams. New membership for Canadian hams is $20; renewals, $18. DX members: the price of new membership is $27; renewals, $25. Remember, though, that these prices include air mail delivery of *The QRP Quarterly*. Send your renewal or new membership request to me at P.O. Box 508, Massillon OH 44648.

There are no special forms to fill out. All I need is your check or money order and your address. Watch your handwriting, though, please: make Us and Vs look like what they are supposed to be.

If you were a member years ago, be sure you let me know. If you don't, you'll get a new membership number. So if you joined the club in 1972, please include your old QRP-ARCI number. Remember, you are a member for life in the QRP-ARCI.

Net worthy

Much to the displeasure of my wife, I keep way too much paper lying around the house. So, to prevent drowning in any more, I've started to surf the World Wide Web in my search for technical data.

If I'm looking for datasheets on semiconductors, I start by pointing my Web browser at Harris Semiconductor. They are at: www.semi.harris.com.

Looking for a special-purpose IC? How about a battery charger chip for your latest QRP rig? Then by all means check out Maxim products. They specialize in portable (low current) ICs and are on the World Wide Web at: www.maxim-ic.com.

Micrel Semiconductor also has its own Web page. They are located at www.micrel.com. Micrel handles low drop out regulators, power supply control chips, and power MOSFET drivers.

Need something from Texas Instruments? Then check 'em out at www.ti.com. On the other hand, if you have no idea where to find that special or unusual part, then a peek at the *EITD* online (the *Electronic Industry Telephone Directory*), with its 30,000 listings, is a must. *EITD* is hiding with *Electronic Component News* at: www.ecnmag.com/eitd.

"That shoots my 'paperless' shack in the butt, doesn't it?"

Most of the Web sites have the datasheets for every part that the specific company makes. You can usually view these datasheets online. However, I like to download them for later use. If you do, you should know that the datasheets are stored in different formats.

By far the easiest to use is Adobe Acrobat. It's free and easily obtained at a zillion sites on the Web. Most of the time, you can get a copy at the same time you download the data files. The best part about Adobe Acrobat is its ability to download a datasheet from the Web for use on either Macintosh-format or Wintel machines. Of course, Adobe Acrobat allows you to print out datasheets, too, if you desire. Then again, that shoots my "paperless shack" in the butt, doesn't it?

Next month

I have a special project for you the next time we meet. I'm not going to tell you that you won't be able to live without this, but it is a lot of fun to build and really does something useful. As a matter of fact, it's not so much a project to build as it is a learning experience...

Until next month, see you at Dayton Hamvention 97!

NEVER SAY DIE

Continued from page 59

requiring specialized equipment and teachers.

In God's Image

Hmm, here goes Wayne again, stirring up the religiously inspired. The ARRL is absolutely right, amateurs should not discuss religion or politics, because in these areas belief is stronger than reason. Indeed, belief is so strong that many people can't tell it from reason, so any attempt at reasoning just makes them angry.

Well, that's never stopped me from upsetting people before, so why should I start now?

The *Bible* says man is made in God's image. Naturally women have a bone to pick over this. Maybe a rib. But since every person is different, I don't understand the "image" concept. Are we talking a Japanese Sumo wrestler? A Hottentot? Liberace? Tom Thumb? Are we talking a one-month-old zygote or a 120-year-old woman?

The people who die and go to heaven, and then come back (NDEs), are consistent in reporting that there is a God, though for some strange reason they seem to lose any interest they'd previously had in the organized religions. None of their reports mention anything about God being in man's image. Or woman's.

Well, we've made an enormous amount of scientific progress in the last hundred years, but little spiritual. Most of our major religions are based on ideas 1,500, 2,000, 2,500, and more years old—ideas expressed in the *Bible*, the *Koran*, the *Talmud*, the *Baghavad-Gita*, the *Vedas*, and so on. I've been reading some very interesting books about how these ideas developed, but I'm sure that devout believers in any of these sacred texts would get very upset from reading about their history.

Okay, so stone me as a heretic. My ancestors were thrown out of Scotland for being religious nuts. They moved to Ireland, becoming the Scotch-Irish. The Irish put up with their baloney for a while and then they, too, threw them out. So they came to America.

How does God handle the billions of other solar systems in our galaxy? And the billions more solar systems in the billions of other galaxies? Did God have a father? If not, where did God come from? Everything has to have a beginning. If there really was a big bang (and the more you look into that whole idea, the less water it holds), was God there before it? So what was God busy doing before there was a universe?

If our universe is expanding, what's it expanding into? Is Earth expanding too? If the universe is expanding, wouldn't Earth have to also be expanding, right along with it?

Now I can see why I should write about DXing instead of religion.

Von Däniken. Again!

Yes, I know, you're a whole lot more interested in who won the last ARRL Directors' election than reading or even thinking about the Sphinx. After all, the professional Egyptologists already know everything there is to know about the Sphinx, right? And the pyramids, too.

Well, having visited the Sphinx a couple of times, and having read more and more about it recently, I no longer trust the opinions of the professional Egyptologists as to its age.

Erich von Däniken's latest book, *The Eyes of the Sphinx*, is a fun read about ancient history. And it's very well documented. He demolishes the experts (a.k.a. prestigious scientists) on the Sphinx and the pyramids.

For instance, none of the experts have come up with a reasonable explanation of how the pyramids could have been built. Von Däniken discusses all of the proposed theories, and destroys them. He cites the theory of Professor Davidovits, an archeological expert, who says the giant stones were not quarried miles away and brought to the site, but were poured, just like concrete. A set of hieroglyphs found in 1889 described the manufacture of the concrete, listing 29 minerals (and where they could be found) and several natural chemicals as the ingredients. When Professor Davidovits mixed up a batch of this cement according to the old recipe, he got a harder concrete which dried faster than modern concrete and was much more

Depending on when you read this, the annual science fair season is either in full swing or just completed. Every year, in most localities, there is a round of science fairs that progresses from the school level to an area fair, to a regional or state fair, up to the international fair. At each level there is a sorting-out process in which some students are selected to go forward and others are not (we never say "lose" because that's not the issue). I usually judge three to six fairs depending on my available time. This year, I did not do as many as in the past because I teach Visual BASIC (a computer language) on Saturday mornings at our local community college.

If you have any technical ability, or if you are trained in any of the sciences or mathematics, then I recommend that you get involved in science fair judging. It's really rewarding to see kids who work in a disciplined manner to ferret out some bit of truth about Nature. While few of them will ever earn a Nobel Prize, or even take up science as a career, there is a distinct learning process going on. Students who negotiate the rigors of even high school science learn to think critically, and to organize facts and data.

Science fairs are not only personally rewarding, but they can also steer youngsters into amateur radio. Perhaps your local club ought to sponsor a special prize, a scholarship, or even just a certificate for the "best of fair." It would certainly get some publicity for the hobby. It would especially be useful if the prize is restricted to students who do something related to radio, or who are amateur radio operators, or something else that is relevant. Most science fairs have a time for special judging by professional societies and other interested groups. The local fair coordinator can get you the information.

If you are a high school student, or have a high schooler in your household, or know and mentor (Elmer?) a student, then you might want to copy the material below and put it to good use.

Winning a science fair

Science fairs are about science, so scientific method counts for a great deal. When I wrote about this subject one time before, a reader (of a different magazine) wrote me a harsh letter and complained that a young friend had been rejected at a science fair because she did not have a stated hypothesis. The claim was made for her that the project was a perfectly valid environmental project and was based on good data. It probably was, but if it doesn't have some hypothesis at risk, then it is doubtful science at best.

"If it doesn't have some hypothesis at risk, then it is doubtful science at best."

A hypothesis is a falsifiable statement of what you are looking for. The term "falsifiable" means that it is capable of being proven false. Indeed, it is often easier to falsify a null hypothesis, i.e., the statement that something cannot occur, than it is to falsify the hypothesis itself. Here's one example. Suppose the hypothesis is that "All cats are gray in color." You can inspect 10,000 gray cats and still not be sure that all cats are gray. Even a single not-gray cat disproves the hypothesis. The example is trivial, and a bit weak, but you get the idea.

Another example—but please, please, please don't try this experiment at home. Suppose the hypothesis is: "Kerosene in an open dish cannot be ignited by tossing a lighted match into it." You can toss a thousand matches into it and see them doused without knowing for sure that the hypothesis is correct. But, if you rephrase the question to: "Kerosene in an open dish can be ignited by a lighted match," a different situation is found. If a single match lights off the kerosene, then the original hypothesis ("cannot") is falsified.

The hypothesis should be written out before the experiment is designed and conducted. Furthermore, when planning the experiment, decide what data constitutes sufficient proof of the hypothesis and null hypothesis. If data collection involves some ambiguity, make a prior decision on how to count each datum. For example, if the relevant data are temperatures, and you classify "above 100 degrees" and "below 100 degrees," then specify beforehand where readings of exactly 100 degrees will go. Some people will place all of the exact readings in one class or another, while others alternate back and forth (i.e., the first 100 degree reading goes in one class, the next in the opposite class). Still others randomly assign the data point to one class or the other.

Do enough trials of the experiment to ensure that the results are significant. Doing three or four trials is probably not sufficient. Perhaps 20 or 30 is better. No one expects high school students to have the resources and time to do some more complex experiments with the number of repetitions that statisticians would like—or that professional scientists would use—but "only a few" is clearly suspect.

It is also critical to do your own work. While that should go without saying, there are always those who have someone else do the work and submit it as their own. Sighhh. Of course, sometimes judges make errors. I recall one youngster, whom I knew personally, who built an electronic project too well. Some judges claimed that he had to have had his father do it for him, because the quality of construction was too good. But I knew the kid had done a lot of projects other than the science fair project, so I intervened and convinced them that his father did not do it. Indeed, he probably didn't know how—he was an accountant with no amateur radio or hobbyist electronics background. The kid's project might as well have been in Greek for all his father knew about it (same with the boy's mother).

Another good trick is to keep a complete notebook on the project. Professional scientific or engineering notebooks are available, but are too costly for most high school projecteers. The standard in science is to use a bound notebook so that other people can tell if pages—perhaps *embarrassing* pages—were removed. One of those speckled black and white "composition notebooks" is just fine at the high school level.

Make all entries in the notebook in ink. Do not attempt to erase erroneous entries. Cross them out, in ink, note the date of the correction, and place your initials by the correction. Close to the same spot write in the correct data, if available.

Make good use of statistics. If you don't know anything about statistics, then get an introductory book. I can immodestly recommend my own book: *The Art of Science*. It has a lot of very good information for the budding scientist, and is well within the intellectual reach of even average high school students. That old bromide about "you can prove anything with statistics," meaning that you can propagate rubbish, or "there are liars, damn liars and statistics," is essentially hogwash. There is only good use of statistics and bad use.

Also, learn what "significant figures" means. If you measure a potential of 1 volt and a current of 3 amperes with the usual measuring instruments, the answer $R = E/I = 1/3$ is not "0.333333333" (or however many digits your calculator can carry), but "0.33" or "0.333" at most; in some cases, it might even be "0.3." The judges are not only not impressed with such seeming precision as "0.333333333," but might be sufficiently *un*impressed to count off significant points for such sloppiness.

The display that you prepare should be as nice as possible. If you have the resources, use your

computer graphics and word processor programs. Mount everything on foam-backed poster paper (or even use one of those three-panel "science fair" displays made from foam-backed poster paper). If you don't have the resources, then hand write—or print—everything as neatly as humanly possible. Judges are generally not impressed enough with the display to award a higher place for bad science, or reduce the place for good science, but in borderline cases the display can make the difference. And if you are good enough to go to the regional or state science fair appearance becomes a lot more significant. At that level, all of the competition is good.

Above all, know your subject and be prepared to answer some questions. If you don't know the answer, then don't try to scam the judge—it won't work. "I don't know" is an acceptable answer if it is the truth, especially when followed by "...but I intend to find out." The essence of good science is the Confession of Ignorance, coupled with the integrity to admit it out loud, and the energy to go find the answer. After all, the professional scientist spends most of his or her time out on the frontiers of knowledge, and out there Nature is very unforgiving of a "know-it-all" attitude. *"Y gwin erbyn y byd"* ("Truth prevails against the whole world"), the war cry of the Iceni (Briton) Queen Boudicca (ca. AD 61) applies to science—but only for those who have the integrity to seek it out.

New book for computer types

If you are into programming or building computers, whether for control of amateur radio, some other practical project, or just for yuks, then there is a book that you need to see. Have you noticed all those accessories that work off the parallel printer port? There's a gazillion of them. Ever wondered how they do that trick, and how you could do it? Then take a look at *Parallel Port Complete* by Jan Axelson. It contains the hardware and software details for programming and interfacing to the parallel port. I've got a copy to review, and it looks great! It can be bought for $39.95 (includes Visual BASIC diskette), and is available from Lakeview Research, 2209 Winnebago Street, Madison WI 53704; phone: (608) 241-5824; FAX (608) 241-5848; E-mail jaxelson@lvr.com. The cover image and additional information can be found at Web site http://www.lvr.com/ppcpress/htm.

NEVER SAY DIE

Continued from page 61

resistant to environmental factors. It wasn't long before a French company started making concrete using this old recipe, and Lone Star has introduced the harder, faster-drying mix in the U.S.

A microscopic examination of a rock sample from the Great Pyramid by Davidovits turned up traces of human hairs.

You can see why I found the book so fascinating. It's published by Berkley Books, ISBN 0-425-15130-1, 278pp, $12.

Von Däniken makes a good case for the Sphinx being up to 10,000 years older than believed by the experts, and the same for the Giza pyramids. The experts disagree, mainly because they say that the technology required to build these enormous structures was impossible that early.

Encouraged and excited by this book, I next tackled Zacharia Sitchin's *When Time Began*. This Avon pocket book runs 410pp, ISBN 0-380-77071-7, and costs only $7. I've got four of Sitchin's books to read. He's done an amazing amount of research in archeology and ancient texts and his books are thoroughly illustrated with these references, so his interpretations of history seem well founded. Interesting stuff, and not what you're taught in school.

It is upsetting to Egyptian historians to admit that the major Egyptian monuments predate Egyptian civilization and thus have to be the product of some other people. Or maybe non-people (aliens).

Oh well, I'm sure that there's no possible connection between endless ancient texts about aliens and the current spate of abduction reports, UFO sightings, the shadowy figures behind the Fed, the Council of Foreign Relations, the Bilderbergs, the Illuminati, and so on. That's all the usual conspiracy hokum. No, let's ignore all that nonsense and worry about the sunspot cycle and when our HF bands are going to come back to life.

Weird Forces

Von Däniken, in his new Sphinx book, explains how the "pyramid effect" was discovered by Antoine Bovis in the 1930s. This is the strange effect which

Communications Simplified, Part 16

Peter A. Stark K2OAW
P.O. Box 209
Mt. Kisco NY 10549

So far we've covered a few of the basic antenna types—the dipole, 1/4-wave vertical, and the yagi beam. Let's look at some more general concepts.

Types of feedline

When an antenna consists of two identical parts, such as the two halves of a dipole or the driven element in a yagi, it can be fed by a balanced line. The two sides of the antenna get equal, but opposite, voltages. For low-power applications, 300-ohm twinlead could be used, but for higher powers, or if line losses are important, an open-wire line is more common. This consists of two conductors, kept apart by insulated spacers every few inches. These spacers have less loss than the continuous strip of plastic used in the twinlead.

But when the antenna consists of unlike parts, such as a vertical antenna and its ground plane, you should use an unbalanced line, such as a coax cable. You can mix and match by using a balun to match a balanced load to an unbalanced line, or vice versa. With a transmitting antenna, however, you must be sure that the balun can handle the power. The balun can be a transformer, as discussed in our transmission line chapter, or it can be made from coax cable.

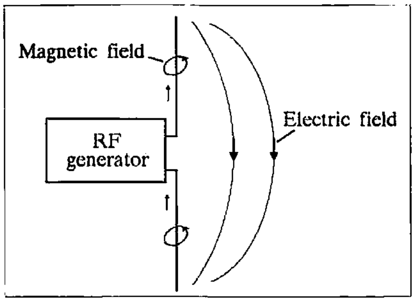

Fig. 1. Fields around a dipole.

People sometimes use a coax cable to feed a dipole; although this works, it greatly distorts the pattern of the antenna, because the coax shield now becomes part of the antenna, and itself radiates.

"There is one concept, often forgotten, that is crucial to success."

The counterpoise

In the electric and magnetic fields of **Fig. 1**, we specifically refer to a dipole, and we show the electric field extending from one end of the dipole to the other. A similar thing occurs with a vertical antenna, except that this time the electric field extends from the top of the vertical whip down to the ground plane under it, as shown in **Fig. 2**. In other words, the ground plane (and the coax shield it connects to) is an integral part of the antenna.

In general, any antenna that directly generates an electric field needs two parts between which the field can extend. If only one part of the antenna is up in the air, then the other part has to be down at the bottom somewhere, so it can act "against" the top part. It is therefore often called the counterpoise.

This is a concept often forgotten by amateur antenna builders, but it is crucial to success. If an antenna does not supply its own counterpoise (such as the other half of a dipole, for example), then an external counterpoise (usually grounded) must be provided.

Loop antennas

Two paragraphs ago, we used the phrase "any antenna that directly generates an electric field." There *are* antennas that do not.

We mentioned that radio waves consist of an electromagnetic field, which is a combination of an electric field and a magnetic field. There are antennas which generate (or detect) mainly the magnetic field; they let the buildup and collapse of the magnetic field generate the electric field which is ultimately necessary to transmit the signal through the air.

A simple example is the loopstick antenna used in almost all AM broadcast receivers. It is simply a short rod of ferrite (an insulating rod which contains metal powder), with a coil wound around it. As the magnetic component of the electromagnetic field passes through it, the coil generates a voltage. The advantage of such an antenna is that it can be quite small—even though a half wavelength at the AM broadcast band is on the order of 1,000 feet or so, the

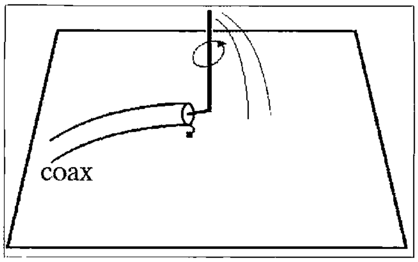

Fig. 2. Fields at a vertical antenna.

loopstick antenna is usually just a few inches long.

There are also several models of commercial loop transmitting antennas. They are not as efficient as some other antennas, but they feature small size. For example, a dipole antenna for the 20-meter (14 MHz) amateur band would be about 34 feet long; a loop antenna for that band is less than one tenth that size.

Collinear antennas

In introducing directional antennas, we discussed using multiple radiators whose signals add in some directions, and cancel in others. Our prior examples used radiators which were parallel to each other; these radiators could also be placed end to end, in which case the antenna is called a collinear antenna, because all the radiators are on the same line.

A common example consists of two or three vertical dipoles, placed one above the other. A receiver at the same height as the collinear transmitting antenna will get the sum of the dipoles' signals, but the signals heading for a receiver at a slightly higher or lower altitude will partially cancel. The effect is to take the dipole's normal vertical radiation pattern, and squeeze it. The normal radiation pattern wastes some signal by sending it down into the ground and up into the clouds; the collinear antenna reduces the radiation in those directions, and sends it out more horizontally.

Nonresonant antennas

You probably know that in a resonant circuit, the capacitive reactance and the inductive reactance are equal, and they therefore cancel. That is, a resonant circuit appears as a pure resistance because the reactance is canceled out. The antennas we've discussed so far in this chapter were resonant also; that is, their length (some multiple of a quarter wavelength) made them appear as a pure resistance load.

DETOUR

When you calculate the length of an antenna in wavelengths, remember to consider the speed of the signal in the antenna wire—the velocity factor. The velocity factor of a plain wire depends slightly on the diameter of the wire, but it is about 0.95, so a 1/4-wavelength antenna would be about 5% shorter than 1/4 of a wavelength in air.

END OF DETOUR

Many antennas, however, are nonresonant, or perhaps resonant at some frequency other than where we want to use them. This adds a capacitive or inductive reactance, which means that there will be some mismatch to the resistive Z_o of the line that feeds them. The common solution is to add just enough of a capacitance or inductance to the circuit to cancel out the reactance of the antenna.

"This trick is often used to shorten an antenna."

This trick is often used to shorten an antenna. For example, a 1/4-wave vertical antenna for the 27 MHz CB band would be about 102 inches long, a bit unwieldy for most mobile operators. The antenna can be shortened, but then it has a capacitive reactance. This can be canceled out with a loading coil (inductance) at the base or near the bottom of the antenna. Likewise, a 1/4-wave whip for a 2-meter amateur handie-talkie would be about 19-1/4 inches long; the antenna can be shortened but then appears capacitive. Many such radios use a rubber ducky" antenna, which winds the antenna in a coil and thus adds inductance to make it resonant.

The disadvantage is that this greatly reduces the efficiency of the antenna. Shortening an antenna by 50%, for example, reduces its efficiency by more than 50%. This doesn't matter much in most receive applications, but is important in a transmitter because the extra inductance tends to heat up and absorb power that should be transmitted.

Feed methods

So far, we've seen antennas with the feedline connected in the middle (as in the dipole or the driven element in the beam) and at the end (in the vertical antenna). Antennas can also be fed at other points, such as slightly off the middle, or at the 2/3 point. In general such antennas do not provide a resistive load, and so some extra capacitance or inductance is needed to make them a good load for the transmission line.

Modern cellular phone antennas are an interesting example of a combination of different feed methods to make a collinear antenna. Most mobile cell phone antennas look like **Fig. 3**. If we break down the antenna into its parts, we see a 1/4-wave vertical at the bottom, with a 1/2-wave antenna above it, making a collinear antenna. But the 1/2-wave antenna at the top is fed at its bottom end rather than in the middle like a dipole. A short inductor between the two antennas takes some of the signal from the bottom antenna and couples it into the top antenna.

Antenna gain

We have shown that directional antennas concentrate the power in a desired direction, and reduce the power going off in undesired directions. This implies that the directional antenna puts out a

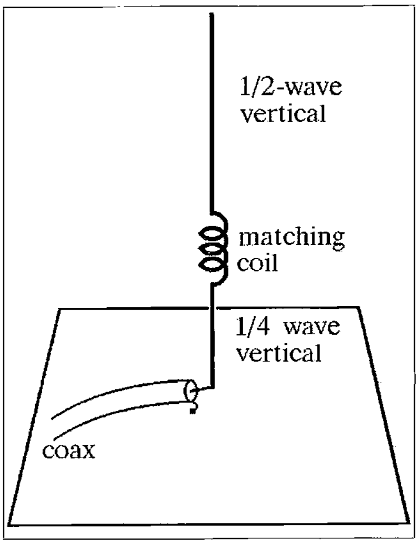

Fig. 3. A common cellular antenna.

stronger signal in its desired direction than a nondirectional antenna would. This improvement is called an antenna's gain. So if one antenna puts out a signal that is 3 dB stronger than that of a nondirectional antenna, we say that it has 3 dB gain. The catch, of course, is that we have to aim the directional antenna correctly.

Well, there is actually another catch, too. Every antenna is directional—there is no such thing as a truly nondirectional antenna, since even a simple dipole or 1/4-wave vertical transmits nothing off its ends. So to be able to do any meaningful comparisons, we have to invent a nondirectional antenna first.

Enter the isotropic antenna. This antenna is impossible to build, but it is useful to imagine it anyway. We assume that the isotropic antenna is (1) perfectly efficient, with no losses, and (2) perfectly nondirectional. All the power it gets from the transmitter is sent out into space equally in all directions.

So let's connect the isotropic antenna to a transmitter with some transmission line. If the power going into the isotropic antenna is P watts, then the Effective Radiated Power or ERP coming out of the isotropic antenna is also P watts.

The idea of ERP becomes important when we consider a directional antenna. Suppose the directional antenna aims its signal so that in some desired direction its signal is a thousand times as strong as the isotropic antenna would be. The word "effective" implies that only the power actually going toward the receiver is useful or effective, so the Effective Radiated Power of this directional antenna is then also a thousand times as large. A 1-watt transmitter feeding such an antenna would put out as strong a signal in this one desired direction as a 1,000-watt transmitter using an isotropic antenna; the 1-watt transmitter and its directional antenna would then be putting out an ERP of 1,000 watts. What this points out is that it is not a good idea to stand in front of a very directional, high-gain antenna, even if the transmitter power is fairly small, because the ERP could still be large.

Back to the isotropic antenna. Suppose we send P watts into it, to be radiated into space in all directions. Let's then build a large sphere around the antenna, and collect all the power it radiates—we should then get our P watts back. (Don't worry about how we're going to do this—this is only a theoretical exercise anyway.)

Since this is an isotropic antenna, every part of the sphere gets an equal amount of power. If the sphere has a radius of R meters (the common unit of measurement for this calculation), its surface area is $4\pi R^2$ square meters. Splitting the P watts into $4\pi R^2$ little pieces, each one square meter in size, tells us that the power hitting each and every square meter of the sphere's surface is

$$\frac{P}{4\pi R^2} \text{ watts per square meter.}$$

This number is called the power density at that distance from the antenna. More generally, since an isotropic antenna getting P watts also has an ERP of P watts, we would write this as

$$\text{power density} = \frac{\text{ERP}}{4\pi R^2} \text{ watts per meter}^2$$

"This antenna is impossible to build, but useful to imagine."

Let's try an example. The power density of a 10-watt signal being transmitted by an isotropic antenna (which has an ERP of 10 watts), calculated 1,000 meters away (about 2/3 of a mile), is

$$\text{power density} = \frac{\text{ERP}}{4\pi R^2} = \frac{10 \text{ watts}}{12{,}566{,}360 \text{ m}^2} = 7.96 \times 10^{-7}$$

which is about 0.796 microwatts per square meter.

Let's now switch to a dipole, still assuming little or no loss in the antenna itself. The same 10 watts of power is now being concentrated broadside to the dipole, with little or no power coming off the ends of it. A receiver broadside to the dipole will now get more of a signal than it got with the isotropic antenna.

Broadside to the antenna, a dipole transmits 1.64 times more power than the isotropic antenna. The dipole therefore has a gain of 1.64 over an isotropic antenna, and the ERP is now 16.4 watts. Translated into decibels, we get

$$10 \log \frac{1.64}{1} = 10 \times 0.214 = 2.14 \text{ dB},$$

so the half-wave dipole has a gain of 2.14 dB over an isotropic antenna. To remind us that the comparison is with an isotropic antenna, we write that as 2.14 dBi (i for isotropic).

Obviously, then, an antenna with high gain has to be very directional, since we never get something for nothing—what looks like gain is just the antenna aiming most of the radiated power in some preferred direction, at the expense of other directions.

Let's continue with our example. Suppose our 10-watt signal were radiated with a test antenna having a gain of 3 dB over a dipole; we say that its gain is 3 dBd (d for dipole). If the antenna has gain, then it is directional and so we must aim it toward the receiver; hence we must talk about the gain in its major lobe.

So we might then ask—what would be the power density 1,000 meters away (in the major lobe, obviously)? We already know the power density for an isotropic antenna, so we need to convert dBd to dBi. If our test antenna has a gain of 3 dBd (3 dB over a dipole), and the dipole itself has a gain of 2.14 dBi (2.14 dB over an isotropic), the test antenna has a gain of 5.14 dBi (you add the two dB ratings).

Using the standard formula for converting power gain into dB, we work it backwards to get a power gain of about 3.27:

$$5.14 \text{ dB} = 10 \log \frac{P_{test}}{P_{isotropic}}$$

$$0.514 = \log \frac{P_{test}}{P_{isotropic}}$$

$$\frac{P_{test}}{P_{isotropic}} = 10^{0.514} = 3.27.$$

In other words, the power radiated in the desired direction (the major lobe) of the antenna will be 3.27 times that produced by an isotropic radiator, and so will the power density. (And our ERP is now up to 32.7 watts.)

In our example, the power density would then be

$3.27 \times 7.96 \times 10^{-7} = 2.60$ microwatts/meter^2.

An easier way to get to this same number is to use the ERP in the numerator of the power density formula, like this:

$$\text{power density} = \frac{\text{ERP}}{4\pi R^2} = \frac{3.27 \times 10 \text{ watts}}{12{,}566{,}360 \text{ m}^2} = 2.60\ \mu\text{w/m}^2.$$

Signal strength

The above calculation gives us the power density a certain distance from the transmitting antenna. However, there are commercial signal strength meters which measure the strength of a signal not as a power density, but in units of volts per meter, and it would be useful to be able to convert from one to the other.

Just as we normally calculate power as

$$\text{Power} = \frac{V^2}{R},$$

so we can calculate the power density as

$$\text{Power density} = \frac{\text{field strength}^2}{R}.$$

But what is R? R is the resistance that the signal goes through in space. Say that again?

This is another concept that requires some more advanced physics. Let's just say that free space (really vacuum, but air is similar enough) has a *characteristic wave impedance* which, for all intents and purposes, is like the resistance R in an electric circuit; its value is 377 ohms.

In this equation, the power density is measured in watts per square meter, while the field strength is measured in volts per meter. To go from a power density to field strength, we have to rearrange the equation to:

$$\text{Field strength} = \sqrt{\text{Power density} \times 377 \text{ ohms}}.$$

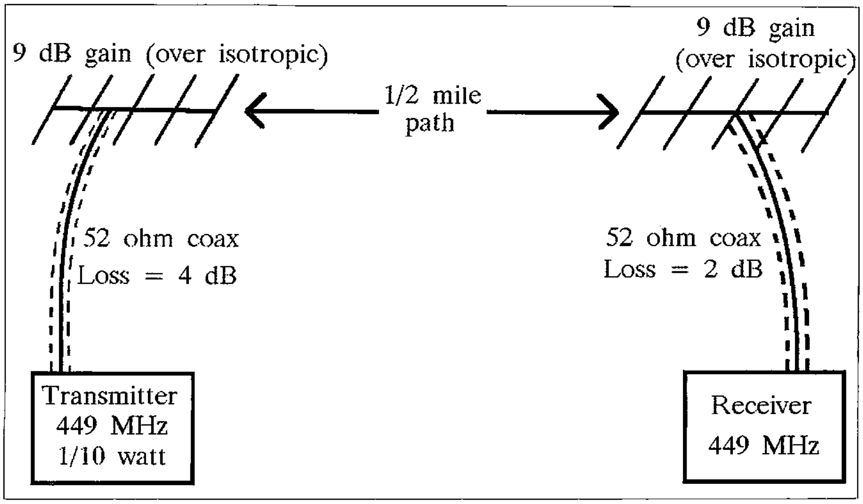

Fig. 4. A practical example from ham radio.

In our example, for instance, we had a power density of 2.60 microwatts per meter^2. The field strength is therefore

$$\text{Field strength} = \sqrt{.00000260 \text{ watts/m}^2 \times 377 \text{ ohms}}$$

$$= \sqrt{0.00098}$$

$$= 0.031 \text{ volts/meter.}$$

Like some other concepts in antenna work, field strength is somewhat theoretical. It is based on the idea that, if you could somehow stick two voltmeter probes into the air, exactly one meter apart, the meter would measure a voltage of (in this case) 0.031 volts. This is not really possible, of course; actual field strength meters measure the field strength by measuring the output from a calibrated antenna.

Field strength calculations can be useful if you ever get your hands on a calibrated field strength meter, but otherwise are not very useful.

Capture area

As you remember, power density is the amount of power that hits a one-square-meter area at some distance from the transmitter antenna. Let's now place an antenna at that point, and make the antenna exactly one square meter in size. If the antenna can capture all the power hitting it, it will receive the same amount of power. For example, if the power density was 2.60 microwatts per square meter, as in our previous example, a one-square-meter antenna would receive 2.60 microwatts of power. If that antenna was two square meters in area, then it would receive twice as much power, etc.

The catch is that the actual physical area of an antenna doesn't always match exactly the amount of power it captures. Some antennas simply don't capture enough of the signal hitting them, while others capture more signal than their size would indicate—they seem to "reach out" into space around them to capture some signal that would otherwise pass on by. So, rather than talk about their physical area, we consider the effective or working area.

The effective area of the antenna is called its capture area. Once we know the capture area, we can compute how much signal the antenna actually receives from the formula

received power = power density x capture area.

The greater the capture area of a receiving antenna, the greater the amount of power it picks up out of the air and sends to a receiver.

As with so many other antenna concepts, the idea of a capture area is purely theoretical. For instance, if it really did what it sounds like it does, namely capture all the power existing in a certain area of space, then a second antenna placed behind the first antenna would pick up no signal at all, and we know that is not true. Similarly, putting a reflector behind a dipole would do nothing because there would be no signal there to reflect, whereas we know that reflectors are commonly used in beam antennas. Still, capture area is a useful

concept because it allows us to calculate other antenna parameters. Specifically, it lets us know how much RF signal a given antenna will pick up and deliver to the receiver.

Measuring the capture area, however, is difficult, so we usually work backwards. Instead of estimating capture area and using it to calculate the gain, we measure the gain and use it to calculate the capture area. The gain of an antenna can be measured by comparing it with that of an antenna with a known gain (such as a half-wave dipole). Once we have that, we calculate the capture area from the following equation:

$$\text{capture area} = \frac{\text{Gain x wavelength}^2}{4\pi}$$

where Gain is the gain compared with an isotropic antenna (expressed as a number, not as dBi), and the wavelength is simply the wavelength of the signal which the antenna is trying to pick up.

Let's justify the equation. It's easy to see why the Gain term is in it—if you double the gain of an antenna, that means it picks up twice the signal, which means that it has twice the capture area.

But why the wavelength^2 term, and why is it squared? Let's consider an example. Let's assume that we have a 3 dBi antenna of, say, 2 by 3 feet. Let's now build an identical type of antenna, but for half the frequency. This new antenna will also have 3 dBi gain, since it is the same type of antenna. Yet every dimension of the new antenna has to be twice as large (because the wavelength is twice as large), and so it has a capture area four times as large. So, although the gain has stayed the same, the wavelength has doubled and the capture area has gone up by a factor of 4. So the capture area is proportional to the square of the wavelength.

Practical example

Fig. 4 shows a typical problem from amateur radio. It shows a 0.1 watt transmitter on 449 MHz, feeding a 9-dB-gain beam through a coax which has 4 dB loss. At the receiver, 1/2 mile away, a similar antenna feeds a receiver through a 52-ohm coax having a loss of 2 dB. Under these conditions, how much signal will the receiver get?

Our calculations go like this:

1) Transmitter power is 100 milliwatts into the coax.

2) The antenna has 9 dB gain, but there is 4 dB loss in the coax cable feeding it, so the total power gain is only 5 dB (in the desired direction!). A 5 dB power gain is a power ratio of 3.16, so the power actually radiated toward the receiver is the same as an isotropic antenna would radiate if it was fed with

3.16 x 100 = 316 milliwatts.

In other words, the ERP is 316 mw or 0.316 watt.

3) A half mile is 1609/2 meters, or 805 meters. The power density at that distance is thus

$$\frac{ERP}{4\pi r^2} = \frac{0.316\ \textit{watt}}{4 \times 3.14159 \times (805)^2} =$$
0.0388 microwatts/meter^2.

4) 9 dB antenna gain on the receiver is a power ratio of 8. (Here's a shortcut to figure that out: 9 dB is 3 dB + 3 dB + 3 dB. Since each 3 dB power gain doubles the power, the power increase is 2 x 2 x 2, or 8.)

The wavelength at 449 MHz is

$$\frac{3 \times 10^8 \text{ meters/sec}}{449 \times 10^6 \text{ cycles/sec}} =$$
0.668 meters/cycle.

With a 0.668 meter wavelength and a gain of 8, the receive antenna's capture area is

$$\frac{\text{Gain x wavelength}^2}{4\pi} =$$
$$\frac{8 \times (0.668\text{ m})^2}{4 \times 3.14159} = 0.284\text{ m}^2$$

and so the received power at the receiver's antenna is

received power = power density x capture area

= (0.0388 μw/m^2) x 0.284 m^2

= 0.011 microwatts.

5) Another 2 dB is lost in the receive coax line; we translate that to a ratio of 1.59 using the equation

$$2\text{ dB} = 10 \log \frac{P_2}{P_1}$$

so the power arriving at the receiver is only

$$\frac{0.011\text{ microwatts}}{1.59} =$$
0.0069 microwatts.

6) Since $P = V^2/R$, we can find the actual voltage at the 52-ohm receiver input:

$V^2 = P \times R$

$V = \sqrt{P \times R}$

$= \sqrt{6.9 \times 10^{-9}\text{ watts} \times 52\text{ ohms}}$

$= 5.99 \times 10^{-4} = 600$ microvolts.

"Figures lie, and liars figure"

Time to tell the truth. The above numbers are all nice and exact—but in practice, things never quite work out like that. There are a number of other factors which don't show up in the math, such as

•What is between the transmitter and receiver antennas?

•Do they have a clear line of sight between each other, or are there obstructions? The above math assumes a line of sight.

•What about the curvature of the Earth—if the antennas are low enough, the Earth may obstruct the path between them.

•Are there any reflections from other objects? Nearby buildings or hills can provide reflections, but so can the earth below! Earth reflections are less likely with vertical polarization, but they can still occur. And reflections can either add to the signal, or cancel part of it; either way, the actual signal strength at the receive antenna can be drastically different.

•How about the coax, antennas, and connections—are they in good shape, or are there additional losses due to old age, moisture, rust, or other factors?

•How well are the antennas aimed?

•Is the polarization of both transmitter and receiver antennas the same?

•And yes... did the antenna manufacturer tell the truth in specifying 9 dB gain?

Since there is so much variability in these factors, it is usually a good idea to assume that the results could be off by a factor of 10 or more. In other words, a real-life system had better provide ten times more power than the calculations indicate is needed. Still, such calculations do give you a rough idea of the *minimum* reasonable power that might do the job.

Path loss

In the above example, we started with a transmitter output of 100 milliwatts and wound up with only 0.0069 microwatts at the receiver. This is a total loss of

$$\text{Loss } in\ dB = 10 \log \frac{0.0069 \text{ microwatts}}{100 \text{ milliwatts}}$$

$$= 10 \log \frac{6.9 \times 10^{-9} \text{ watts}}{1 \times 10^{-1} \text{ watts}}$$

$$= 10 \log (6.9 \times 10^{-8}) = -71.6 \text{ dB}.$$

Let's see what the signal had to go through on its way from the transmitter to the receiver: a cable at the transmitter; a transmit antenna; half a mile of air; a receive antenna; and some cable at the receiver. Let's then add up the losses in each of these:

Cable at the transmitter	-4 dB
Transmitter antenna	+9 dB
1/2 mile of air	-X dB
Receive antenna	+9 dB
Cable at the receiver	-2 dB
TOTAL	-4 + 9 - X + 9 - 2 = +12 - X dB

But we already know that the total loss is 71.6 dB, so

$$+ 12 - X \text{ dB} = 71.6 \text{ dB}$$

$$X = 83.6 \text{ dB}.$$

In the above example, the antennas actually contributed an 18 dB gain (9 dB for each antenna), while the cable loss added up to 6 dB (4 dB at the transmitter, 2 dB at the receiver). This adds up to a total gain of 18 - 6 = 12 dB. In other words, we had an effective gain of 12 dB in the antenna systems, and still lost 71.6 dB in the transmission; this means that the loss in the 1/2-mile path was actually 71.6 + 12 = 83.6 dB. This is called the path loss.

"Did the antenna manufacturer tell the truth?"

The path loss is actually dependent only on the distance and the frequency. It is calculated by assuming that isotropic antennas are used at both the transmitter and receiver, and there are no other losses in the coax cables. We then use the foregoing equations to calculate, step by step, the received power in relation to the transmitted power.

Alternatively, we can combine all of the above equations into one big equation which gives the path loss directly in dB:

$$\text{Path loss } in\ dB = 10 \log \frac{(4\pi)^2 \times \text{distance}^2}{\text{wavelength}^2}$$

where both the distance between the transmitter and the receiver, and the wavelength, must be given in meters.

The path loss is useful not only in cases where we want to get a signal from one place to another, but also in cases where we don't. For example, suppose a 2-meter receiver is located 1/5 mile (322 meters) away from someone else's transmitter on a nearby frequency; in other words, the nearby transmitter might interfere with our efforts to receive a weak signal. How much interference will the transmitter cause to the receiver? The path loss is a guide to how much the transmitted signal will be attenuated in the 1/5-mile path:

$$\text{Path loss } in\ dB = 10 \log \frac{157.91 \times (322 \text{ m})^2}{(2 \text{ m})^2} = 66.1\ dB.$$

This means that if both the transmitter and receiver have isotropic antennas and no loss in the coax, the received signal will be 66.1 dB weaker than the transmitted signal. In an actual case, you would have to add in any antenna gains, and then subtract cable or other losses, so the actual signal loss might be smaller once these are taken into account.

Quartz Crystals

An overview of these frequency controllers.

Hugh Wells W6WTU
1411 18th Street
Manhattan Beach CA 90266

Hams have been fascinated by quartz crystals since their first use. They and other people involved in radio have used quartz crystals for many years, perhaps without understanding the material.

Quartz has been recognized for at least 7,000 years and was originally used as jewelry. Around 1880 Professor Pierre Curie discovered the piezoelectric effect of quartz. This effect is the one used in radio crystals; it refers to the vibration of the crystal in the presence of an electric field.

Dr. Walter G. Cady took out a patent in 1920 on quartz as a means of controlling and measuring radio frequencies. At the time, most transmitters were self-excited and lacked frequency stability. With few stations and lots of frequency spectrum to work with, the instability was of little concern.

However, today it is another matter. Frequency stability and control are extremely important with the crowded bands. Quartz crystals have provided the means of controlling frequencies easily. Not too long ago, a radio required a crystal for every discrete frequency; today only one or two crystals are required in a frequency synthesizer to provide the stability required for all of the frequencies generated by the synthesizer.

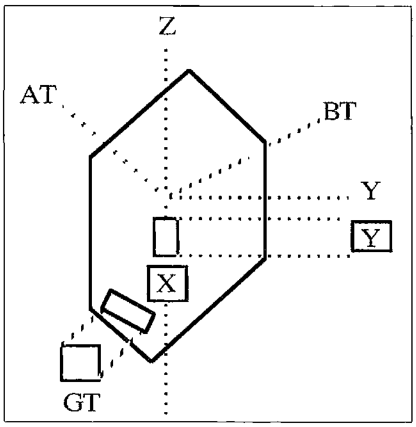

Fig. 1. Some of the different cuts available from a quartz bar.

Synthetic quartz

At one time, all of the quartz used for radio crystals was natural quartz material. Most of the world's supply of radio grade quartz was obtained from South America, and specifically from Brazil. But with a diminishing supply of high grade radio quartz and with increased demand, the development of synthetic quartz increased rapidly. Synthetic quartz, also called "cultured" quartz, was developed in 1845, even before piezoelectric effects were known.

Synthetic quartz is grown using hydrothermal techniques. Polycrystalline quartz is dissolved in a hot alkaline solution and then re-crystallized. Fragments of natural quartz are used as seed crystals to start the process by providing the model for crystalline structure growth from the solution.

The difference between natural and synthetic quartz is minimal as far as users are concerned, and usually involves imperfections in the crystalline structure of the synthetic material. These imperfections are detected and discarded at the time of material grading, before making usable radio crystals.

It is interesting to note that the structure of synthetic quartz is considerably more uniform than natural quartz. The purity of synthetic quartz has provided a higher yield of radio grade quartz than was ever obtained from natural quartz. The final result is a lower cost to the user.

When a crystal is ordered from the factory, the user seldom knows much more than whether the crystal is a fundamental or overtone type. **Fig. 1** shows some of the different cuts from the quartz bar. Each of the cuts has a name, such as AT, BT, CT, GT, etc. The various cuts exhibit different characteristics, which crystal manufacturers take advantage of to produce a crystal suitable for each application.

The crystal bar has three main axes, X, Y and Z. These axes are really directions and are related to the physical property of the material (**Fig. 2**). The Z axis is the easiest to identify because it runs the long way from end to end of the bar. The X axis runs in a direction through the corners of the bar and 90 degrees from the Z axis. The Y axis is a direction through the flat side of the bar and 90 degrees from both the X and Z axes. All of the specific crystal cuts are oriented from these axes.

Quartz use applications

The first usable cuts made from a quartz bar were from the X axis. Later the Y cut was introduced because it was easier to excite in an oscillator circuit than an X cut. However, the Y cut stability tended to be poor and it could change frequency abruptly. During World War II, crystal cuts such as AT, BT and CT were developed to reduce the effects of

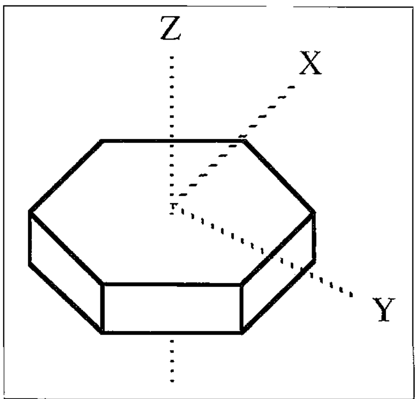

Fig. 2. Quartz bar slice, showing the X, Y and Z axes.

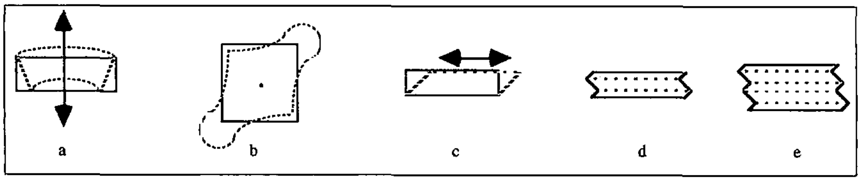

Fig. 3. Relative frequency range and mechanical movement: (a) Fundamental flexure mode 10 kHz - 100 kHz. (b) Fundamental face shear 180 kHz - 1 MHz. (c) Fundamental thickness shear 1 - 20 MHz. (d) 3rd overtone 5 - 61 MHz. (e) 5th overtone 50 - 125 MHz.

temperature and abrupt shifts in frequency. The AT cut is now the most popular for radio applications, but BT, CT and GT cuts are used extensively to meet stability and overtone requirements as a function of temperature and excitation.

A quartz crystal is cut with a saw running in a slurry containing diamond dust. Originally only one saw blade was used, allowing one crystal blank to be cut at a time. Now, a gang saw is used so that many crystal blanks can be cut in a single pass. Once cut, each blank is graded and finished to customer requirements.

Quartz responds to the effects of an electrical field by creating a mechanical movement (piezoelectric). The relative frequency range and mechanical movement are shown in **Fig. 3**. Fundamental low frequency crystals with their large mass vibrate to create the appearance of a pillow. At higher fundamental frequencies, the crystal appears to squirm (rotate about its center line). During overtone operation, the crystal appears to vibrate in shear. The number of shear layers produced are odd in number; that three layers produce the third overtone (third harmonic of the fundamental). Five layers would produce the fifth overtone, etc. The overtone frequency produced, although not controlled by the fundamental mode, is a near multiple of the fundamental (about 25 kHz per overtone higher). When being produced, the crystal is processed for the end use frequency and overtone mode of operation with no concern as to what fundamental properties it might have.

In operation, the quartz crystal functions just like a coil and capacitor in a resonant circuit and can function as either a series or parallel resonant circuit. Fig. 4 shows the equivalent circuit of a crystal which can be used to define the operation of the crystal exactly. The inductance L represents the mass of the crystal, the capacitance C1 represents the resilience, and the resistance R represents the frictional losses. Capacitor C2 represents the crystal electrodes across the crystal as a dielectric. Capacitor C3 represents the series capacitance of the crystal and the electrodes. Depending upon the mode, the circuit can represent either a series or parallel resonant circuit. When the combined reactance of C1 and L are inductive and equal to the reactance of C2, the crystal will operate in the anti-resonant mode (parallel resonance). When the reactance value of L equals C1, the crystal will operate in the resonant mode (series resonance).

When operating a crystal in an oscillator circuit, capacitor C2 may be paralleled with a trimmer capacitor to cause a small change in the crystal's anti-resonant frequency. If the crystal is operating in the overtone mode, either series inductance or capacitance will cause a crystal frequency shift. External frequency adjustment must be used sparingly as crystal stability will be affected. **Fig. 5** shows the reactance curve of a quartz crystal and the small difference between the resonant and anti-resonant points. Notice that the resonant (series) frequency is slightly lower than anti-resonance (parallel). In the resonant mode, the crystal exhibits a low impedance across its terminals, and a high impedance across its terminals when in anti-resonance.

One of the biggest user concerns about quartz crystals is the aging factor. In other words, how much will the crystal drift after it is placed in operation? Quartz crystal aging applies to the cumulative change in frequency, which results in a permanent change in the operating frequency. The rate of change is the fastest during the first 45 days of operation. Many interrelated factors are involved in aging, some of the most common being internal contamination, excessive drive, surface change of the crystal, various thermal effects, wire

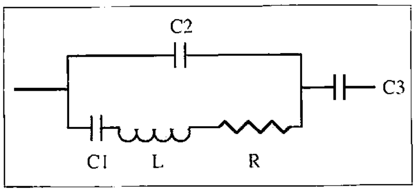

Fig. 4. Equivalent circuit of a crystal which can be used to exactly define the operation of the crystal.

fatigue and functional wear. Proper circuit design incorporating low operating ambients, minimum drive level and static pre-aging will greatly reduce all but the most severe aging problems.

Vibration

Quartz crystals vibrate when operating due to their piezoelectric characteristic, although the amount of vibration is quite small in relation to the physical size of the crystal. Even though small, the vibration causes stresses in the structure, which generates heat. If not kept within limit, the internal stress can cause permanent damage through rapid aging and/or fracturing. Excessive oscillator drive can cause severe stresses to occur. Once fractured, of course, the crystal is no longer of any value.

Vibration of the crystal also creates heat which can adversely affect the operation and stability of the crystal. Frequency drift is the usual symptom of heat. To keep the crystal temperature down, the oscillator drive level must be kept as low as possible, usually below 1 mW for crystals used as a standard frequency reference. Overtone crystals may require 1-2 mW of drive, while fundamental crystals operating below 10 MHz may require up to 10 mW. The drive level should be cut by 50% of the above indicated values when the crystal is used in an oven.

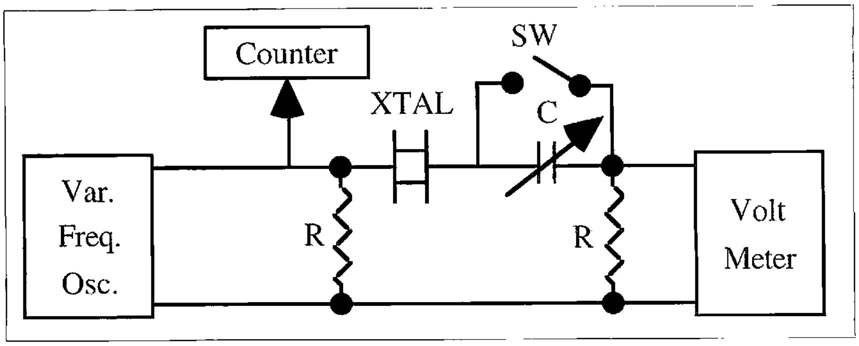

Fig. 6. Crystal test circuit.

The amount of crystal drive is usually related to the amount of crystal activity required, and in this case refers to the ability of the crystal to vibrate. Some crystal test oscillators have a meter in the circuit to indicate the relative strength of activity. The amount of crystal activity indicated by a meter is vague, but nevertheless provides a reference.

Many things control the amount of activity that a crystal will exhibit. For the older style pressure-mounted crystals, dirt and mounting conditions were a major factor. Modern hermetically sealed crystals are not affected by the environment. Therefore, manufacturing techniques, the Q factor of the cut and frequency will affect the drive level requirement. Of importance, though, is the ability of the crystal to start easily in the circuit and maintain a given frequency. The amount of drive applied should be just high enough to create reliable oscillator stability and operation. A large drive value could cause fracturing or excessive aging.

Testing a crystal

Parameters of a quartz crystal can be tested by placing the crystal into a passive network, as shown in **Fig. 6**. A variable frequency oscillator is used to drive the crystal, which is mounted in a pi network of equal value non-inductive resistors. An RF voltmeter is placed on the output to measure the signal transferred through the network. For phase angle measurements, a vector voltmeter may be placed in parallel with the crystal. Being passive, the crystal will respond to the drive frequency at both its resonant and anti-resonant frequencies. Actually, the crystal operates/responds as a filter. Using this network, it is possible to measure the phase angle of the voltage across the crystal (zero degrees equals resonance, 180 degrees equals anti-resonance), determine the crystal impedance and equivalent resistance and determine the crystal's load capacitance. The load capacitance can be determined by placing a capacitor in series with the crystal while it is connected in the network and then measuring the voltage vector across it. As an example, the frequency of the oscillator is set to the anti-resonance frequency of the crystal (180 degrees of phase shift across the crystal), then the value of the series capacitor is adjusted until a phase angle of 180 degrees is obtained across it. The total phase angle between the oscillator and network output is 360 degrees. The value of the series capacitor is equivalent to the load capacitance value (typical values range from 20 to 32 pF).

Not all of the parameters are needed to use the crystal in an oscillator; but the more that are known, the simpler it is to design the oscillator.

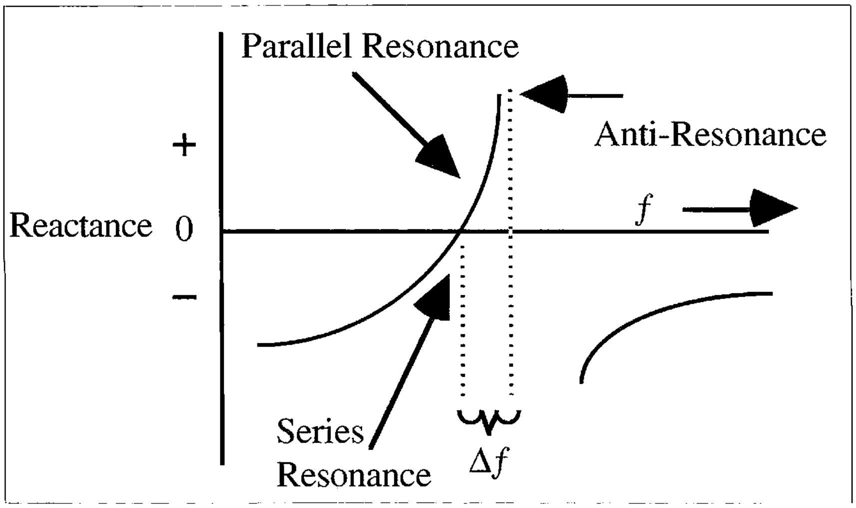

Fig. 5. The reactance curve of a quartz crystal.

10 Meters Lives!

Don't let the sunspot cycle fool you.

Phil Salas AD5X
1517 Creekside Drive
Richardson TX 75081

Have you tried 10 meters lately? I know. I know. We're at or near the bottom of the sunspot cycle and 10 meters is useless—or *is* it?

I've been finding this band opening up frequently. It often opens from the late morning through the afternoon. I've also found it open occasionally to as late as 10:00—at night! One recent Saturday evening I got on 10 meters at 8:00 p.m. and worked K2YJL/mobile in Kentucky running a Uniden 2510, NØKXL in Kansas running a Uniden 2510, and KF4BGR in Florida running an Emperor TS-5010. K2YJL told me he has confirmed 170 countries over the past two or three years operating mobile with his Uniden 2510 and Hamstick™ antenna! I suspect that 10 meters has *always* had openings, even during lows in the sunspot cycle. Most rigs nowadays have scanning capability. Go ahead and put your radio on scan so you'll find out when the band opens. Incidentally, the belief that 10 meters is dead has resulted in some great deals on the above-mentioned rigs. To give you a personal example, I recently traded an unused microphone for a mint condition HTX-100!

OK, you've scored that 10-meter rig from a less-than-savvy, but happy, previous owner (he thinks *you* got the short end of the deal). Now you need an antenna or two to get going.

For 10-meter base station operation, I recommend a high horizontal antenna. I've found that a high horizontal antenna usually outperforms a ground-mounted vertical or ground plane antenna by several S-units.

Recycle that, good buddy!

Look for used CB antennas at hamfests. A dipole made from two slightly shortened CB whips back-to-back at 20-25 feet up in the air will do a great job. For the dipole center, use a PVC "T" attached to the top of a PVC or aluminum mast attached to your chimney with a cheap hardware-store chimney mount.

To attach the CB whips to the PVC "T," use PVC reducers and 1/8-NPT brass adapters as shown in **Fig. 1** (all available from your local hardware store). As it turns out, 1/8-NPT is the same as a slightly tapered standard 3/8 x 24 antenna thread. You can chase the 1/8-NPT threads with a 3/8 x 24 tap but this isn't really necessary unless you'll be screwing and unscrewing the elements frequently.

Pick the "T," reducers, and adapters to fit your mast. The 3/4" PVC "T" shown has an inside diameter of one inch, because it must pass over the one-inch outside diameter of 3/4" PVC pipe and so it will take a one-inch OD aluminum mast. The CB whip bases screw directly into the 1/8-NPT thread.

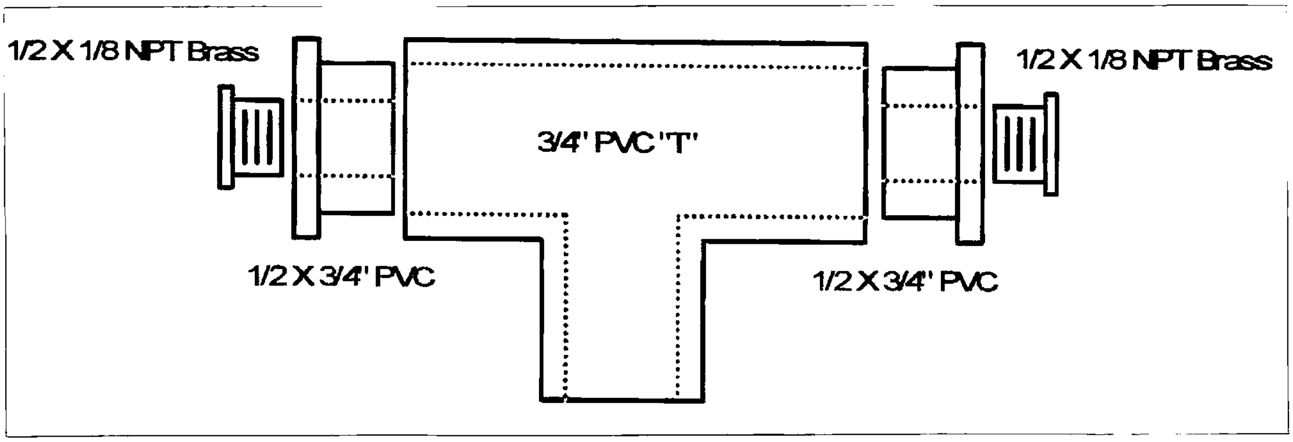

Fig. 1. Dipole center piece.

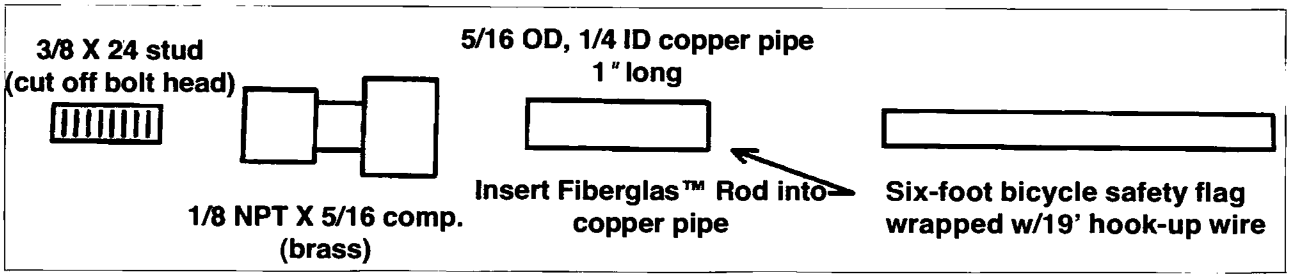

Fig. 2. Mobile antenna details.

To attach your coax, drill and tap holes in each of the brass adapters to take a #6 brass screw. Attach a solder lug to each adapter with brass screws (use brass or copper lockwashers). Solder the shield to one solder lug, and the coax center conductor to the other solder lug.

Alternately, you can just drill a small hole in each brass adapter and solder a wire to the hole to use as the connecting point for your coax (solder to the brass adapters *before* they are mounted in the PVC, or you'll have a melted PVC mess on your hands!).

If you're a real purist, you can also add a balun, but that's not really necessary if your coax exits the antenna at right angles and stays that way for a while.

Goin' mobile

When you're shopping for those used CB antennas for your base station dipole, think about a *third* CB whip for your car. Operating mobile will add another exciting dimension to your ham fun. The Uniden, Radio Shack, Lincoln, Emperor, etc., rigs are all small enough to fit easily in all cars. My Uniden 2600 mounts vertically on the transmission hump in my Geo Metro and causes no problems to the passenger (normally the ever-critical spouse). Incidentally, the CB antennas need to be shortened about four to five percent to put them on 10 meters. An MFJ or Autek SWR analyzer will permit you to get everything perfect in an amazingly short time!

Mobile antennas for 10 meters can be made inexpensively by shortening CB antennas as mentioned above—but you can "roll your own" low profile (six feet) 10m mobile antenna for even less!

As you can see in **Fig. 2**, a mobile antenna can be built from a 6-foot Fiberglas™ bicycle safety flag (around $3 at discount stores), 19 feet of #22-24 hookup wire, a one-inch-long piece of 5/16" OD (1/4" ID) copper pipe, a 1/8-NPT x 5/16 compression brass adapter, a 3/8 x 24 bolt, and some 3/8" heat-shrink tubing.

To build this antenna, solder one end of the hookup wire to one end of the one-inch-long copper pipe. Put some epoxy on one end of the Fiberglas rod and slide this end of the rod into the copper pipe. Next, insert the copper pipe into the 5/16" compression fitting and tighten. Screw a 3/8 x 24 stainless-steel bolt into the 1/8-NPT end of the brass adapter and tighten securely (the 1/8-NPT tapered thread makes a nice interference fit). Cut off the head of the 3/8 x 24 bolt and file off the rough edges as necessary so it will screw into a 3/8 x 24 mount. Now, wrap the wire evenly around the whip and hold the end of the wire in place temporarily with masking tape. Mount the antenna on your car and check the resonant frequency with your SWR analyzer.

"Operating 10m mobile will add another exciting dimension to your ham fun!"

If the resonant frequency is too low, you can either remove some wire or compress the turns at the top of the antenna. If the resonant frequency is too high, compress some turns around the center of the antenna. With just a little effort, you can adjust the turns and turn spacing to resonate this antenna right where you want it. Incidentally, the SWR at resonance will probably be around 1.5:1. Since most radios aren't bothered by a 2:1 SWR and the cable loss will be negligible, you really don't need to worry about this "high" SWR. However, if you want a perfect 1:1 SWR match, connect a 25 pF 500 WVDC silver mica capacitor from the base of the antenna to ground. Make sure you make the antenna adjustments with the capacitor in place.

When the antenna resonates where you want it, add a few pieces of heat-shrink tubing along the length of the antenna to hold the wire in place. You now have a flexible, low profile, and low wind resistance 10-meter mobile antenna for less than $7! This same method works for other frequency band antennas, too.

I turned my Uniden 2600 into a dual-band 10- and 12-meter rig by adding the Chipswitch™ to it, so I also needed a 12-meter mobile antenna. The Chipswitch (available from Chipswitch, 4773 Sonoma Hwys, Suite 132, Santa Rosa CA 95409-4269, FAX 707-539-7571 or phone 707-539-0512), permits continuous operation between 24.5 and 30 MHz for Uniden and Lincoln 10-meter rigs. For my 12-meter mobile antenna, I started with 20 feet of wire and was easily able to get the antenna to resonate in-band.

I also built a 15-meter mobile antenna which required 25 feet of wire. For frequencies below 10 meters, the base matching capacitor becomes more important for keeping the SWR reasonable. I needed 50 pF on 15 meters for a 1:1 SWR.

Ten meters is not as dead as many folks think—and it's easy (and inexpensive) to get on the band. I've given you some hints on obtaining inexpensive 10-meter rigs, and information on building inexpensive base and mobile antennas. When the sunspots finally start to appear, you'll have a head start on all the fun.

HOMING IN

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92633

New ideas never cease

Friendly competition, international goodwill, emergency rescues, self-policing, and wildlife management—what do they have in common? All are important uses for radio direction finding (RDF). Whether your interests in ham radio are technical, social, or public service, RDF can play an important part.

When I talked to *73*'s then-editor Bryan Hastings NS1B in the summer of 1988 about a monthly RDF column, he was interested but skeptical. He asked, "Do you really think there is enough material for a full year of columns?" I nervously assured him that I had a long list of topics.

Next month's "Homing In" will be Number 100. With your help, this department has presented stories of transmitter hunters in action from cities and towns all over the country. There have been reviews of new commercial RDF gear and projects to build at home; also, the first detailed coverage by a major ham magazine of APRS, LoJack™, and Teletrac™ has been on these pages. There was even a turtle-tracking expedition. Despite all this, my list of potential topics is longer than ever. Technical innovations are coming at an increasing rate and T-hunters are always finding new ways to have fun.

If you are new to *73* and want to see what you have missed in "Homing In," you will find a complete chronological index at my site on the World Wide Web (http://members.aol.com/homingin/). Don't forget the forward slash at the end of the address. If you don't have Web access, send me a self-addressed stamped envelope and I will mail you a copy.

"Some hams from China are proposing a new type of ARDF contest they named the Technical Session."

***Photo A**. Want outdoor fun for your ham club's picnic, hamfest or Scout troop? Hold an IARU-style foxhunt! A new rules proposal makes it easier than ever.*

T-Hunts—grass roots growth

As it was when the first "Homing In" appeared, mobile hidden transmitter hunting is still the most popular use of RDF by hams in the USA, and it's growing. I regularly hear from clubs that have just begun to sponsor T-hunts. A good example is the Silver Creek Amateur Radio Association (SERA) of Doylestown, Ohio, near the cities of Akron and Canton. According to Jim Korenz N8PXW, SERA holds hunts once a month, except in winter. They start from a shopping center parking lot in Doylestown or Barberton.

"Most of our hunts are not too sophisticated," Jim says. "They run about 20 or 30 miles maximum. Parts of the area are rural but it's still fairly urban. Most of the time, the person with the fox is in a car by the side of the road or in a park."

Simple 2-element quads or yagis are most popular for 2m RDF in N8PXW's area. Jim prefers his home-built Roanoke Doppler with a wideband antenna set of four magnetic-mount whips (see "Homing In" for April and June 1995). Having learned about microcontrollers on the job, he decided to see if they could augment his setup. "I acquired a Motorola GPS board in Dayton and decided to link the two together," he told me. "I increased the clock frequency from 8 kHz to 64 kHz. This gave me 7 bits of angle data. I got the eighth bit from the clock chip. I latched the data with a 74LS374 octal latch and fed it to a Motorola 68705P3 microcontroller by way of the 8-bit data port.

"The processor converts the 256 counts into 360 degrees, puts the number into an ACSII message, and transmits this data via RS-232 to a display processor for the GPS," N8PXW continues. "That display processor is also a home-built 68705P3 unit, which receives the NMEA format messages from the GPS, parses the data, and sends the values to the LCD display. It also receives the Doppler data, adds the GPS-determined heading for the vehicle, and displays the signal bearing relative to true north.

"The GPS processor outputs the latitude, longitude, and bearing as an ACSII message from another RS-232 port. The data is sent only when the vehicle speed is greater than 5 mph and three or more satellites are seen by the GPS. I tried to average the bearing data with the processor, but the eyes seem to do a better job."

As experienced hunters know, the performance of Dopplers versus RDF beams depends on the nature of the hunt. "The Doppler usually works very well," Jim says. "On my first hunt, I arrived about 20 minutes before anyone else, but I placed second because the hunt was scored by mileage, and mine was one mile longer than the winner. The worst experience with the Doppler was when I was within a half mile of the T in a dense forest of large trees. All the indicator did was continuously spin around in circles with no obvious direction."

SERA hams have learned that a prepared group of T-hunters helps to minimize malicious QRM on local repeaters. "Last year we had a jammer who would put out whistles and dead carriers," says N8PXW. "At first he was on maybe once a week, but by Christmas he was on all the time, including midnight and early mornings. So four teams started looking one night. Home stations with beams said he was south of Doylestown, so we took

off and ended up in the country with no signal to hunt. Now I know what it feels like to be a private eye—a lot of sitting on lonely roads with people going by saying, 'What are you doing out here? It's 20 degrees!'

"A couple of nights later, the whistler was on pretty solid again," Jim continues. "I could hear him on the input from home, so we went out again. I got out on the freeway past the local airport and the Doppler kicked in, pointing due south. I got three good bearings and then the signal stopped for the night. The readings crossed in the city of Massillon.

"We all went down there the next night. I couldn't detect the signal from the south and east of Massillon, but some of the other guys picked it up from the west and north. We didn't find it. However, one of our young hams got on the repeater next morning saying, 'My dad was out in Massillon, real close to the jammer.' We haven't heard the QRM since."

For the latest SERA hunt schedule, send E-mail to: w8wky@amsat.org. If you are in the area, call on the 147.39 repeater.

ARDF—a new attitude

On-foot radio-orienteering (ARDF) is the fastest growing form of competitive direction finding outside the USA. In many countries of Europe and Asia, it is a school sport with regional, national, and international championships. North America has a long way to go to catch up to the level of ARDF activity in International Amateur Radio Union (IARU) Region 1 (Europe/Africa) and Region 3 (Asia and South Pacific). Nevertheless, this year's spring thaw will bring out ARDF enthusiasts in several cities of North America.

At the ARDF Working Group meeting in Bulgaria last year, a new age category, Veterans, was officially added to European events. In it are men age 56 and older. Seniors (men ages 19 to 40) must find all foxes on the course to win. Contestants in other categories, including Veterans, need to find only four.

With the addition of Veterans, there are now four categories for males and only one for females (see **Table 1**). The four-to-one ratio did not sit well with some delegates. A formal proposal was put forth one month later to have four categories for women as well, with the same age ranges. The proposal, written by OK2BWN and DL5NBZ, would require those in the M20 category (men ages 19 through 40) to find all five foxes. Males and females in all other categories need find only four, except for D56 (women 56 and older) who would have to find only three.

Is the proposal fair or is it discriminatory? That will be debated by the Region 1 ARDF Working Group when it meets in Germany this September. Meanwhile, you can read the complete proposal text at the "Homing In" Web site.

A serious impediment to the growth of stateside ARDF is the mandatory logistics and organizational effort. IARU's official "Rules for Championships in ARDF" is 12 pages of fine print that specifies in great detail how courses must be set up and competitions must be run. Following these rules requires carefully synchronized transmitters, individual timing and starting of competitors, plus other restrictions that make it necessary to have a staff of non-hunters to oversee the event.

2m IARU championships must use AM transmitters and MCW fox signals, which are incompatible with the equipment and skills of most new hams. The courses are large (at least 500 acres), so only true athletes have a chance of winning. With the realization that these rules and restrictions are discouraging many ham hobbyists from trying ARDF, some hams from China are proposing a new type of ARDF contest that they named the Technical Session.

	VHF Class (IARU Rules)	Technical Session (BA1HAM Proposal)
Categories	Juniors (boys under 18) Seniors (men 18 to 40) Old Timers (men 41 to 55) Veterans (56 and older) Women (any age)	Youngsters (boys under 14) Gentlemen (men 15 to 55) Old Timers (56 and older) Ladies (any age)
Site	Predominantly wooded	Any kind of field
Total course distance	5 to 10 kilometers	1 to 3 kilometers
Number of foxes	5	8 to 12
Min. fox separation	400 meters	5 meters
Verification method	Distinctive punches at foxes	Unique control numbers
Dummy controls?	No	Yes, 2X to 5X number of foxes
Fox placement	Visible with red/white flags	Concealed, invisible
Mode	2 meter AM	2 meter FM simplex
RF carrier	Keyed and modulated	Modulated
Transmitter power	0.25 to 1.5 watts	100 to 200 milliwatts
Antenna polarization	Horizontal	Vertical
Foxes heard at start	All	At least half
Identification	8-12 WPM CW, MOE, MOI, etc.	Slow CW, single character
Timing	1 minute on, 4 minutes off	3 seconds on, 30 seconds off
Synchronized?	Yes, in numbered sequence	No, slight timing variations
Map	1:20,000 orienteering	Simple with roads and buildings
Start method	Five minute intervals	All together

Table 1. Comparison of rules between the traditional IARU two-meter foxhunt and the proposed Technical Session. The total course distance is the minimum path from start to each transmitter and then to the finish.

Chen Ping BA1HAM has circulated a draft proposal. If adopted, a Technical Session would be added to regional and national championships. It would be separate from the existing 80m CW and 2m AM events, with separate competitor categories and prizes. **Table 1** shows my comparison between rules for the traditional 2m run and the Technical Session. The proposal text can be downloaded from the "Homing In" Web site.

Technical Session courses would be smaller than those of other IARU foxhunts, so they could be held in city parks and school grounds. Besides the obvious convenience, a small course makes the outcome more dependent on RDF skills and less on the ability to run fast. Other features would make it possible for visitors and observers to be on the grounds during the event and for contestants to use commonly available VHF-FM receivers and scanners.

Note that age categories are slightly different from mainstream IARU foxhunts, to recognize the differences in technical abilities between children and teenagers. Furthermore, entrants in all Technical Session categories are expected to find all foxes; the number is not reduced for any category.

As an additional incentive to improve RDF abilities, foxes would be truly hidden, with no prominent flags nearby. Numbered markers replace the present orienteering punches. Competitors would write down the number on their cards when they find a fox. To make sure that hunters use their RDF gear instead of just their eyes, there would be many dummy markers in the field. Hunters who write down a dummy number on the card instead of a correct number will score lower.

The Chinese are by far the strongest ARDF competitors in IARU Region 3. They took individual and team gold medals at the Championships in Australia last summer. BA1HAM is Chairman of the IARU Region 3 ARDF Committee. Thus you can be sure that the Technical Session proposal will be given serious consideration by radio-orienteers worldwide.

I like the proposal, because it sanctions foxhunts in local venues with commonly available equipment. However, I would like a more descriptive name such as Short Course or FM Event. Furthermore, I suggest that voice identification be permitted to replace CW for some or all foxes at the event organizers' discretion. Voice memory ICs are plentiful and inexpensive, making talking foxes more practical than ever. They would encourage non-hams and no-code licensees to try ARDF.

The only problem that I envision is security of the marker numbers. Runners should be cautioned to keep their cards concealed so that others on the course cannot see the marker numbers written on them. Course marshals must be watchful to prevent collusion among team members by sharing of numbers. Do you have any ideas for a simple but more secure verification system?

Let's try it

The Technical Session structure is ideal for a foxhunt at the site of your next hamfest or club picnic. So why not hold one? Let's try the proposed rules and see how they work. If you can't put out a dozen foxes, try it with a half dozen or fewer. Here's how to do it:

Visit the site in advance to choose a starting area and a finish area. If everyone starts at the same time, the start and finish can be at the same place. Putting the start/finish area at the center of the venue will encourage hunters to scatter instead of follow one another.

It is not necessary that all foxes be copyable from the start point, but at least half of them should be. The entire hunt area should be free of hazards such as highways, railroads, and dangerous animals. Mark on the map any area with hazards so that no one will venture there.

Make up carry-along cards to give each hunter. There should be a square on the card for each fox, into which the hunters will write the control number for that fox. Standard orienteering cards by Silva have 20 squares and are ideal for this purpose.

The easiest way to make foxes for a Technical Session is to borrow some handie-talkies. Older models such as the Icom IC-2A are perfect, because bells and whistles such as CTCSS are unnecessary. Voice ID can come from an audio chip; on/off timing can be synchronized by a CMOS 555 timer IC. For more controller ideas, see the "Homing In" Web site.

Foxes should transmit for only a few seconds, about twice a minute, sending a distinctive letter in CW or voice. It is OK if transmitters occasionally QRM one another, but try to randomize the timing so that this does not occur on every transmission. Use multiple frequencies only if equipment limitations such as rock-bound transmitters prevent foxes from all being on the same frequency.

Ideally, foxes should begin to cycle just as the hunt starts, so no one can hear them earlier. The versatile PicCon controller described last month can be programmed to start and stop at predetermined times, but most other fox controllers cannot. It may suffice to hold the hunt on an obscure frequency that is not announced until starting time. Forbid hunters from turning on their receivers until then.

Make up about fifty 4-by-6-inch index cards with different 3-digit numbers on them, to be used as control cards. Put the foxes out well in advance so potential hunters won't see you deploying them. Place a control card within six feet of each fox, secured to prevent it from blowing away in the wind. Put out and secure the remainder of the cards at interesting places where hunters might guess that a fox would be located.

Have each hunter register on a roster. Add columns to the roster for start and finish times and number of foxes found. If you have a large enough number of participants, break them into categories with separate prizes for each, to even the field. The Chinese proposal for categories is in **Table 1**, but you could choose differently, as determined by your club's demographics and its opinions about fairness.

Instruct the hunters that they must not turn on their equipment until they begin to hunt. Tell them the hunt frequency and the number of transmitters, plus how the foxes are modulated and identified (voice, CW, letters, numbers, callsigns, and so forth). Give out maps of the hunt area showing boundaries, roads, buildings, terrain features and any forbidden areas.

Start the hunt and begin timing. Make sure you have sufficient help at the finish line to write down exact ending times of each finisher on his or her card and the roster. (The time of finding each fox is not important, just the time that the hunter crosses the finish line.)

Primary scoring criteria is the number of foxes correctly identified by control number. The secondary criterion is time. In a 12-fox hunt, the first to find all twelve wins, followed in time order by all who find twelve, then in time order by all who find eleven, and so forth.

Please let me know what you think of the Chinese proposal. I especially want to hear from clubs that actually try out the Technical Session. I will pass along your results and suggestions to the ARDF Committees of Regions 1 and 3. Send E-mail to: Homingin@aol.com or postal mail to the address at the beginning of this article. Who knows? Maybe there's a future ARDF World Champion in your town!

"The entire hunt area should be free of hazards such as highways, railroads, and dangerous animals."

Above & Beyond

VHF and Above Operation

The VHF/UHF beam antenna

This month, let's cover the construction of an antenna for the 70 cm (432 MHz) amateur band. I didn't want to put together a long-boomer type of antenna with 25 to 32 elements. I wanted to construct a 10- or so element beam on a boom length of six feet. A modest antenna by any measure—not a killer beam. The target price to beat when making a comparison to a commercially available similar antenna was $90 to $100.

I found a good starting point in an article in the May 1989 issue of *Ham Radio Magazine* (pg. 9, K1FO). The task begins by putting together a shopping list of the major components: 1-inch aluminum boom material and a selection of two different tubing sizes for the elements. A larger size is needed for the driven element and still another smaller size for all the others. The ratio of the larger to the smaller diameter should be about 2:1. That is, if 1/4-inch tubing is used for the driven element, the "T"-match section used for the feed arrangement should be 1/8-inch-diameter. The entire antenna is constructed using the 1/8-inch material for all elements except, of course, the driven one. This is constructed from 1/4-inch aluminum rod or tubing. Only a short piece less than 14 inches long is needed for the construction of one antenna.

Other materials recommended in the article were some fasteners to hold the elements in place and an insulating rod to insulate the driven element from the boom. A bracket needs to be constructed out of a small scrap of aluminum to hold an "N"-type female coaxial connector. To this bracket and connector a 1/4-wavelength coax balun is attached which in turn makes connection to the 1/8-inch "T" part of the antenna feed system.

The feed system of the antenna is attached to 1/2-inch insulating standoffs bolted to the bottom bolt holes of the "N" connector. The connector and its mounting bracket are positioned on the boom so as to place the ends of the standoffs and the attached 1/8-inch "T" rods over the center

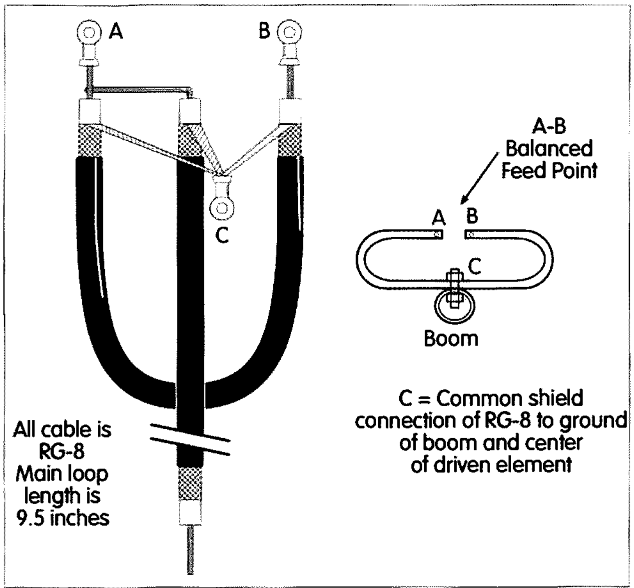

Fig. 1. RG-8U coax balun for 432 MHz is 9.5 inches long, converts 50Ω unbalanced to high-Z balanced configuration.

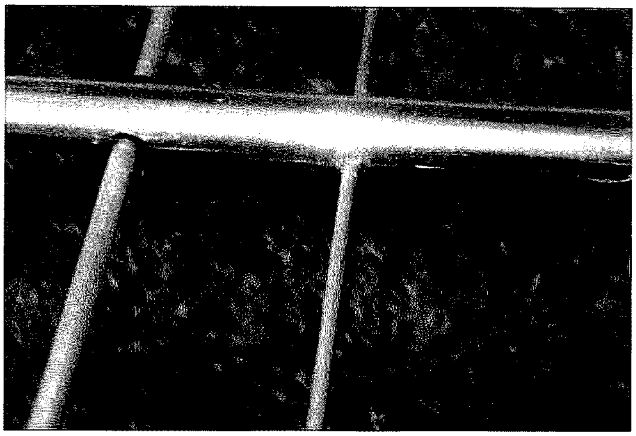

Photo A. *Close-up of new antenna construction showing black-insulated driven element and lighter color (silver) Auveco push-on retainer for smaller driven one.*

of the 1/4-inch driven element. The ends of the 1/8-inch rods are pounded flat to accept a 6/32 screw to attach them to the standoffs. The far ends of the 1/8-inch rods are held in place with a strap made from 1/4-inch-wide thin aluminum bent over to the elements and held in place with the 6/32 screws.

The RG-8 coax feed is fitted with a balun of 1/2 wavelength of coax. To figure out how long 1/2 wavelength is, divide your desired frequency into 300. That is, 300/432 = wavelength in meters, or in this case, .694444 (or more commonly, 70 centimeters) for one wavelength. Divide 70 cm/2 = 35 cm. At 2.54 cm per inch, 35/2.54= 13.77 inches multiplied by the velocity factor of coax (.69) = 1/2 wavelength of coax for our balun 9.5 inches long (see **Fig. 1**).

Wow! Lots of things to accomplish in the construction of this 432 MHz 10-element beam, and we haven't even started to drill holes. Let's look at the assembly of the components and examine the process. I started out to locate a source of 1-inch aluminum thin wall tubing and small-diameter material suitable for the element construction. On my first telephone call, I was able to locate tubing in 12-foot lengths of 7/8-inch material for $7. There was no stock of small-diameter tubing at this source, so I had to make other calls to attempt to locate the material for the elements.

I was trying to keep the materials sourcing in my local area in order to limit excessive mileage costs from picking up all the components needed. I felt that since I lived in a reasonably large manufacturing area spotted with hi-tech materials suppliers, such supplies should not be too hard to find. However, locating small-diameter tubing proved to be difficult. I was able to locate 1/4-inch and 3/16-inch solid aluminum rod at one dealer, but finally ended up purchasing 1/8-inch solid rod at another. All material was in 12-foot lengths. Total cost for the small diameter rod, $8.25.

Materials still on the shopping list included insulating bushings for the driven element; hold-down fasteners for the elements; small bits and pieces like nuts and bolts; and a "U"-bolt bracket to hold the antenna boom to the mast pipe. And, we still needed to construct a coaxial balun 1/2-wavelength long.

Well, according to documentation on this antenna which was reprinted in *The ARRL Handbook* from the original old *Ham Radio Magazine*, the fasteners for the elements could be obtained at any well stocked hardware store. They were made by Auveco Products. *However*, if I had known all along what I know now—that Au-ve-co stands for Automotive Vehicle (products) Company—my search for the fasteners would have been made more than a little bit easier.

I called hardware wholesalers and came up blank trying to find these fasteners. They are similar to the push-on retaining nuts used in the construction of a child's wagon, except that they do not incorporate the hood of the jam nut. The desired fasteners are like a shakeproof washer that has

internal fingers bent out in a cone shape of a particular diameter. This cone shape enables these washers to be slipped over a rod to firmly grasp it in position. Each element is then centered between two such devices to become locked in place (see **Photo A**).

Not only was I unable to locate the fasteners, but I also couldn't find anyone who thought I was sane. The largest hardware stores, in business for some 100 years, didn't know what I was talking about. If they didn't know, I was in trouble. Well, somewhere in my travels I had learned that these fasteners were not part of the normal nut and bolt trade but were instead automotive in nature. My first phone call to a large automotive parts warehouse landed me the phone number of a specialty nut and bolt firm, not listed in the Yellow Pages, that was located in another city and stocked automotive hardware. One call to them put me in touch with reality—they had stock of quite a number of Auveco fasteners.

Unfortunately, amidst all the excitement of getting ready to take my trip over there, I forgot to bring along samples of the elements and the diameters I needed to deal with. So just to be safe (and especially since I'd had to take time off from work to go to this place to begin with), I decided to ensure the success of the project by purchasing a small stockpile of fasteners in various sizes. Cost, $28. I most certainly overbought and will have these fasteners around for some time. I just wanted to cover all the bases.

This "run for the fasteners" trip took my memory cells back to the very early days when we used (steel) electrical conduit for boom material. The elements were 1/8-inch brass brazing rods and the method of attachment was simpler. We drilled a slightly undersized hole in the boom and then shoved the brazing rod through it, making a tight fit. Then, we drilled a second hole offset 90 degrees through the top of the boom for insertion of a sheet metal screw slightly off center from the brazing rod element. The sheet metal screw secured the brazing rod by jamming its threads along the side.

Electrical conduit (steel) for boom material was very inexpensive ($1/10 feet). Brass brazing rod or even aluminum clothesline solid wire could be used for elements. I used brass brazing rod 1/8-inch in diameter. If I remember correctly, the brass rod was a little short for 2-meter elements and I had to solder on some small-diameter tubing to lengthen them. However, for 220 and 432 MHz these smaller elements allow simple construction. Because this was to be a very economical beam antenna (costs held to a minimum), construction techniques were dictated by the materials on hand. Jamming sheet metal screws to hold elements tight to the boom will eventually result in rust, but the method works and will last quite a long time.

The rusty connection will not disturb basic antenna operation but will in time become a simple diode. This diode in many cases

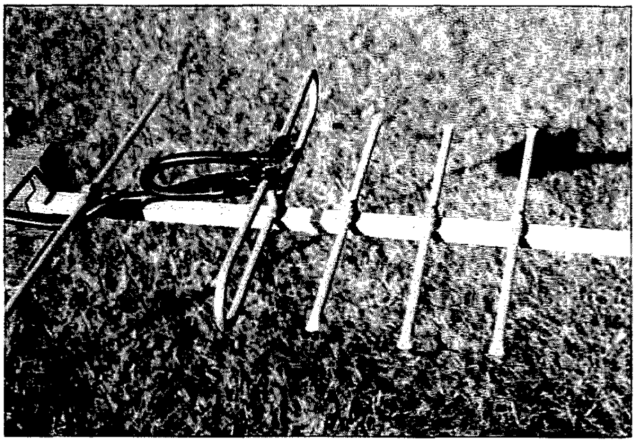

***Photo B.** Repaired 432 MHz beam antenna with balun attached. Antenna with broken elements was purchased at a swap meet for $1.*

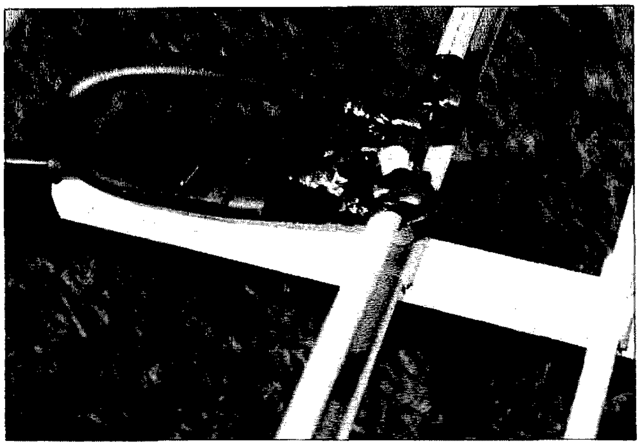

***Photo C.** Close-up of new balun assembly for salvaged antenna, constructed from 9 inches of RG-8 coax.*

will actually become a very good mixer. When joined with some metal (the elements), it allows two transmitters to mix together to produce an interference product. While the product is not very strong, it is capable of being detected by the very sensitive receivers we use for communications today. The modulation that is passed is usually that of the capturing (strongest) signal being mixed.

This mix product can be sufficiently strong to be received quite a distance from the mixing device. The only cure is to remove the rust (mixer) or to bond the metal together to eliminate the rusty connection.

I once came across an example of this in the commercial realm, involving a city emergency frequency and a radio taxi company's commercial one. The problem went unnoticed for many years because at that time mobile transmitters were not left on all the time but instead were activated only when needed. Because the offending transmitters both need to be on the air to observe the mix products, it took quite a bit of air time to discover just what signals were mixing. The mixing culprit in this case turned out to be a city water tower that was assembled with nut-and-bolt construction.

Now, these bolts were quite large and over the many years since construction had become rusty and painted over. This condition made the water tower a better transmitter at VHF than some conventional low-power transmitters. Turning on both transmitters and DFing to the water tower on the interference product became simple. The solution to this perplexing problem was to weld the bolts themselves to the metal water tower structure. Amateur locations can be just as susceptible to this type of problem as commercial radio sites are.

Well, what conclusion did I reach from trying to build a beam antenna and from all the effort needed for home construction? Being a junk box addict, I still opt to construct my own antennas when possible, but I will temper the construction methods used and not go every time for the ideal components to use.

The up side of this whole construction affair was that my partner in electronics experimentation Kerry N6IZW had picked up a small 400 MHz beam at a swap meet for $1 (see **Photo B**). It was missing the driven element and matching section, but I constructed a balun from a short section of RG-8 (**Photo C**) and replaced the broken element with some scrap aluminum. Testing the antenna showed resonances at the 432 MHz SSB frequencies (1.2:1) and still a good match (1.5 to 1) up into the 440 MHz FM region.

That's it for this month. Has the newly constructed antenna functioned well? Well, no: I haven't constructed the feed arrangement yet. When it's tested, I will let you know. Is it better to purchase a small antenna or construct one? This time around, it was too time-intensive to build, so we bought used instead. Next time, who knows? 73, Chuck WB6IGP.

Build a Colloidal Silver Generator
continued from page 25

Colloidal Silver Generator Parts List	
Component	Radio Shack #
Transformer, 24V 450 mA	273-1368
Switch	275-634
AC cord	278-1255
Fuse Block	270-739
1/4 A fuse	270-1002
Bridge rectifier, DIP	278-1181
7806 regulator	276-1770
Green LED	276-022
Neon lamp	272-707
1,000 µF 50 V capacitor	272-1047
270 Ω resistor	271-1314
Plastic box	270-224
Binder post jacks	274-661
Fine (.999) silver is available from Holtzer & Miller Co., (800) 462-7747	
Bare circuit boards are available from FAR Circuits, 18N640 Field Court, Dundee IL 60118, (847) 836-9148	
Parts kits, silver electrodes, and assembled and tested circuits are available—contact the author for details	

Laser Backscatter Tester Parts List	
Component	Radio Shack #
741 op amp	276-007
10 k pot	271-282
.1 µF capacitor	272-1069
.01 µF capacitor	272-1065
Switch, double pole	275-636
Battery snaps	270-324
Solar cell*	276-124
Plastic box	270-224
0-1 mA meter**	270-1754
680 kΩ resistor***	N.A.
*The plastic bubble used to package the solar cell is used for the sample tray.	
**This meter is marked "0-15 VDC" but includes an external 15 k resistor. DO NOT use the external resistor.	
***Radio Shack does not carry a 680 k resistor. It is available from other sources, or connect a 470 k and a 220 k in series.	
Visible diode LASER module is available from M.P. Jones & Associates, Inc., (800) 652-6733. The part number is 6996-LZ.	

Disclaimer

As an ebonics-speaking friend of mine might say, "I don't want no f— trouble from de mf— FDA." This is mostly an electronics-oriented journal, so If someone you know wants to mess around with silver (or other metal) colloids, and is too ignorant to hook three little batteries together to make 'em, you can probably help them by building this simple circuit.

The alternative health-care ("this is a food supplement, not a medicine") field is no more honest than our commercial medical industry—it just isn't backed with the strong arm (a.k.a. swat teams) of the law, as enforced by the FBI, FDA, NIH, WHO, and so on through the Washington alphabet.

With the exception of a warning by Dr. William Douglass in his Second Opinion *newsletter, everything else I've read has encouraged people to take silver colloids internally. Douglass, whom I respect, even though he doesn't answer his mail, says silver is a dangerous toxic metal. If there are any studies which show silver to be toxic, I haven't seen them referenced yet—maybe you can research this and let me know.*

Meanwhile, I am not recommending that you chugalug silver colloids, nor is the author of the article. If you do it and find wonderful health benefits, that's your decision. If you swallow the stuff and your teeth turn black, I don't want to hear any whining. If it kills you, well, we all have to go sometime, right?

I'm working on a booklet on how to make and use silver colloids, so I'd appreciate anything you can find about using it, pro and con. This is yet another case of where, despite a bunch of evidence supporting the value of silver colloids, the medical industry has refused (as far as I've been able to find out) to research their potential—presumably because the results could not be patented and sold for egregious profits...Wayne.

NEVER SAY DIE
Continued from page 63

keeps meat put in a pyramid-shaped container from rotting and which also sharpens razor blades. If the effect is a delusion, then it is able to delude an electron microscope. Check page 176ff for details. Okay, smarty, how can a small cardboard or Plexiglas pyramid sharpen a razor blade or mummify meat?

The normal scientific approach is to declare that all researchers claiming such an unexplainable effect have made errors.

So how about dowsing? Thousands of years of dowsing studies are all flawed, right? Sure.

Then we have the work of Wilhelm Reich and his orgone generators. Our beloved government put Reich in prison (where he kind of died) and destroyed his laboratory and orgone generators. A friend of mine, Dr. Charles Dockum, with whom I worked on a Guggenheim Grant project for the Guggenheim Museum on Fifth Avenue, built

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

New technology

With all the recent comings and goings in the amateur radio market, it's exciting to be able to talk about one of the most innovative technologies to come down the pike in years.

We are all familiar with the common types of modulation forms in use to transmit radioteletype over the air. The classic, most common, method is frequency shift keying, of course, with a MARK and SPACE signal used to represent the two states of the RTTY loop. With the traditional method of encoding Baudot five-level code at 60 words per minute, or 45.45 bauds, each pulse lasts 22 mSec, and has a square waveshape.

It has come to my attention that cutting-edge amateurs have been able to impress a second digital signal on the flat top of each 22 mSec pulse. This allows a phase shifting signal to ride on top of the amplitude modulation of the radioteletype signal. The utility of this quickly becomes obvious when a logarithmic form of encoding is used, with inversion of the impressed amplitude on the wave top.

A practical application currently under investigation allows a computer-linked, object-oriented graphic to be fixed in linkage to the frequency-shift-keyed signal. By splitting this object off during reception, real-time graphics are now possible over a low-bandwidth, 45.45-baud signal.

I look forward to being able to tell you more about this technology, officially called the Amplitude/Phase Ratio, Inverse Log, Fixed-Object-Oriented Linked System, within the next several months. Stay tuned!

On a more direct note

Hugh Phillips K7XM writes that he is looking for a good standalone RTTY program to use with his (late) AEA PK-232. Well, Hugh, several programs, including LanLink, PakTerm, and PaketPet all come to mind. Each has its own flavor, and each its advocates and critics. But that's, as I tell my children, why Baskin-Robbins has 31 flavors. Check out the various programs available in the RTTY Loop Software Collection—I'll remind you how later—and see if one, or more, doesn't suit your fancy.

Another message from T. John Lewis VE3LGS, addresses the problem of the ham not living in the United States. He says: "I have been an avid reader of RTTY Loop for many years but in the past few have gotten away from real RTTY to the 'fad' modes. I would like to get back on RTTY. I have several TUs just gathering dust which work perfectly. I see that you have a program called AUTORT on a disk you mail out to persons who send an SASE and US$ to you by mail. Since it is impossible to get US stamps here in Canada without driving to the USA, I wonder if there is another easier way. Is there an Internet address where it can be downloaded?"

John, although I have been trying to get a number of programs up "live" on the RTTY Loop home page, space considerations prevent me from having them all on-line at the same time. After all, there are more than 20 Mb of programs and data, quite a bit more than the space allotted by my Internet Service Provider. I understand the problem, though, of folks who may want just one program, or who have problems with stamps or mailers. If you need just one program, I can attach it to an E-mail reply, presuming you can download binary files from the Web. If you only have a text service, such as some of the "freemail" servers, you may not be able to retrieve such files. They are a bit long to UUENCODE, so getting a disk the old-fashioned way may be your only solution at that point. If you have a question, drop me a line. Let's talk.

As the communication wave spreads out from the Internet, there is bound to be some confusion among those not familiar with amateur radio. I received the following questions, which I have massaged a bit for the purposes of generality, and present them here, with answers. Maybe one or two of these will help you in discussing digital matters with friends and coworkers.

> *"This new technology is officially called the Amplitude/Phase Ratio, Inverse Log, Fixed-Object-Oriented Linked System..."*

Q. Is there a way of accessing some of the ham resources on AOL and CompuServe if you have another Internet service provider? AOL and CompuServe are only available overseas through an expensive phone call.

A. While both AOL and CompuServe are normally accessed via their own telephone networks, both can now be accessed by subscribers via the Internet as well. I would advise checking the Internet home pages of each service (http://www.aol.com and http://www.compuserve.com, respectively) to look into these options. Offhand, I don't see why Internet access should not be available to non-USA users.

Q. I am about to retire and go sailing. While I am practicing my Morse code and may succeed in getting an amateur license before I leave, may I operate an SSB radio aboard ship while yet unlicensed?

A. Not on amateur bands, you can't! Get that ticket first!

Q. May I operate an amateur radio aboard the boat while unlicensed using only those frequencies which have been allocated for marine SSB telephony?

A. Amateur is amateur and marine is marine. One has nothing to do with the other. If you want to operate on amateur frequencies, you need an amateur license.

The bottom line is not to confuse the two services. The radios may look alike, and the signals may sound alike, but they are different animals.

And finally, I received a question about a PK-80 given to a ham who did not pass along his name. He wondered if this unit, originally designed for the Radio Shack TRS-80, would work with a current PC-type computer. You know what? I don't know! As I recall, the PK-80 was a simple interface, which depended on software programming to perform the digital conversions. Offhand, I don't see why, with suitable software, the PK-80 wouldn't work with a PC. I look forward to reader input on this one.

I mentioned the RTTY Loop Software Collection. This sixteen-disk (as of this writing) collection of RTTY software and utilities features a wide variety of programs of interest to digital amateur. On-line amateurs can check out the list on the RTTY Loop home page at http://www2.ari.net/ajr/rtty/. If you cannot connect, a self-addressed stamped envelope to the post office box above will get you a printed listing. Either way will fill you in on the details of how to obtain any of the disks of the collection. I welcome your comments, questions, suggestions, and critiques at the P.O. box, or via E-mail at ajr@ari.net.

Next month, I'll try to pry my tongue out of my cheek, or have you not understood the opening paragraphs yet?

Continued from page 81

a small orgone generator and used it to cure a wide range of illnesses for friends. They're very easy to build, by the way.

More hokum? Or anomalies worthy of investigation?

The government certainly isn't going to fund research into weirdom like this, nor are any large corporations, so that leaves it up to independent researchers. And since there are no experts in these fields, researchers are going to be amateurs, not professional scientists. But then, virtually every major new discovery in science has been made by an amateur, and all have been ridiculed and humiliated by the scientific elite (a.k.a. prestigious scientists) every inch of the way.

Another Gloom & Doomer

The Survival of Civilization by John Hamaker. Hamaker-Weaver Publishing, R1 B158, Seymour MO 65746; ISBN 0-941-55000-1, 1982, 218pp, $12. Hamaker is all upset over the rapid increase in CO_2 levels, predicting the end of the world. I want a second opinion. But he does make a good case for remineralizing the earth. A very good case. Ever since listening to the Dr. Wallach *Dead Doctors Don't Lie* tape, I've been looking for more information on the loss of minerals from our topsoil.

As Hamaker points out, to look at them you can't tell the difference between crops grown using NPK (chemical) fertilizers and remineralized crops, but one is healthy and the other sure isn't. So what's remineralization? This has to do with grinding up rocks to replace the minerals which have either been leached out of the soil, plus the minerals plants have extracted and which have not been returned. Once the farms were "played out" the farmers had to start using commercial fertilizers to keep their crops growing. The problem is that this robs us of the minerals our bodies need to keep healthy.

How effective is remineralizing the soil? The USDA ran a test with seven steers fed the usual fodder and another seven fed the exact same diet with 3.5% cement kiln dust added. The dust-fed animals gained 28% more weight and ate 21% less feed. Imagine how healthy you and your family might be if you were getting all the minerals your body was designed to use, but which you haven't been getting in your supermarket food!

The Federalist Papers

John Jay wrote that "Nations in general will make war whenever they have a prospect of getting anything by it." Pacifists should face up to that reality. Wars are prevented by making it too dangerous for others to attack you. Weakness produces subjugation, not peace. Our forefathers had no illusions about people. Madison wrote, "Enlightened statesmen will not always be at the helm." Amen! The Constitution was designed to take that into account and limit the damage that foolish leaders could do. When the Constitution is observed, it works pretty well. When federal judges ignore the Constitution or get particularly creative in interpreting it, we sure get into a heap of trouble. (My thanks to Thomas Sowell for bringing up the subject.)

History has continually confirmed John Jay's observation. As much as pacifists hate the idea, history has shown that strength is the best guarantor of peace, not unilateral disarmament—but can you think of any peace movements which have operated on this principle?

The idea, unsupported by history, that if people get to know one another they won't fight, has been kicking around peace movements for ages. So how come the Hutus in Rwanda were so easily incited to murder around 800,000 of their erstwhile friends and neighbors, the Tutsis? And just a couple of generations ago the Germans were able to wipe out millions of Jews and Gypsies? And so on.

So let's smile and be friendly Americans, but carry a big stick, to coin a phrase.

Sharks!

While in Aspen skiing, in January, Sherry bought some books at a secondhand store. One of them was a book that I've been wanting to buy for some time, *Sharks Don't Get Cancer* by Dr. Wm. Lane; Avery Publishing, 1993; 192pp; ISBN 0-895-29520-2; $12. Lane makes a very convincing case for shark cartilage being able to cure just about any cancer, as well as arthritis, psoriasis and macular degeneration.

As with other non-pharmaceutical remedies, the medical industry has been fighting this as quackery. Lane points out how reactionary the industry is. Despite endless claims for the Heimlich maneuver for choking victims, the American Red Cross refused to accept it for ten years, continuing to endorse back-slapping, which causes a stuck object to be even tighter stuck in the throat.

The money in the trillion-dollar medical industry (the most profitable industry in the US) is in drugs which can be patented, so if an illness isn't to be cured with a drug, there's no organization to research the proposed cure. Well, you ask, how about the National Cancer Institute? Surely they'll check out any proposed cancer cure, right? Wrongo. It turns out that the NCI "does not deal in cures for cancer, but only in the mechanisms of cancer." Maybe that helps to explain why so many reported cancer cures have been completely ignored by the NCI. And since about 50% of us are going to have a personal brush with cancer at some time in our lives, maybe we need to better educate ourselves and depend less religiously on our doctors.

Shark cartilage isn't patentable, so there's no pharmaceutical company to pony up the $231 million it costs to get a new drug okayed by the FDA, so you'll have to buy the stuff in health food stores as a dietary supplement.

But first, for heaven's sake read the book. It could save your life. Or, better yet, wait until you are almost dead from cancer or crippled with arthritis and *then* spend the $12.

ZL Media Flurry

When the results of an international test showed their students placing 14th in the world, the New Zealand media raised quite a fuss. But when American students placed 14 places below that, our media just ignored the matter. As the costs of communications and transportation keep dropping, much better educated workers in other countries are, more and more, going to be replacing American workers.

If you are an employer you know what I'm talking about. Finding educated workers with any motivation is getting to be almost impossible.

The bottom line is that your children are not going to get a decent education in a public school. At the very least you should be doing some home schooling to make up for this sorry situation, which is being vigorously protected by the teachers' unions.

Privacy Please

If someone is interested in assuming your identity all they have to do is get your name, current address, Social Security number, your previous address, your mother's maiden name, your birth date, and so on. This is all now available from Lexis-Nexis (Box 933, Dayton OH 45401) via their P-Trax data base. Yes, you can protect yourself. Call 888-965-3947 and request that your name be deleted. They'll tell you how to request the deletion in writing. If the wait is too long on the above number you can try 800-543-6862 and contact Andrew Bleh (blay) at extension 3385. His manager is Bill Fister at extension 1365.

Let me know how you make out.

Self-Abusers

Sherry pointed out that virtually all of the troubles I've had with employees stealing or causing me other serious problems has been from self-abusers. Smokers and alcoholics, who don't care enough to take care of themselves, are not likely to be good employees. This is a pretty good rule.

State of the Art

In late January I got a call from Art Bell W6OBB asking if I was game to appear on his talk show again. Sure. I knew what I was getting myself into, but the end seemed to justify the means. We talked for five hours, from 2 to 7 a.m. Eastern time. We started out talking about amateur radio and then wandered into cold fusion, my theories on aliens, how to make money, my list of books you're crazy if you don't read, the Bioelectrifier, silver colloids, and then more amateur radio. By the end of the day we'd had over a thousand phone calls asking for more information. These tapered off over the next few days, but then the mail began to pour in, if you call 300-400 letters a day a

Continued on page 84

FCC FCC Issues Issues

Imagine using your newly issued amateur radio callsign on the air, only to find out that someone else also has the same callsign! Of course, that's not supposed to happen. But it did, to at least a handful of newly licensed hams in the southeast US. The FCC blames the callsign snafu on computer problems.

The foul-ups started happening in mid-October. That's when the FCC issued the same callsign to several people who had just passed their license tests. Louise Williams KF4MTE of Newberry SC is a case in point. She was assigned KF4MTO on October 23rd—that same callsign wound up being issued seven days later to another woman in North Carolina. Two days after that, on November 2nd, KF4MTO was again assigned, this time to a woman in Tennessee. At least two other South Carolina hams had similar experiences.

The Commission was having computer problems for about a week, just before Gate 2 vanity callsigns were issued. A spokesman said he has no idea how many licenses may have been issued to more than one person. It's possible that there might be more hams who are unaware that they are operating with a license holding the wrong callsign. But the Commission's database has been corrected so that there are no callsigns with more than one holder. In the case of more than one person getting the same callsign, the last person to be assigned the callsign got to keep it.

An FCC spokesman says it appears that the problem of multiple people issued the same callsign is apparently limited to first-time licensees only.

Thanks to South Jersey Radio Assn. *Harmonics*, January 1997, which got it from *ARRL Electronic Letter & Newsline, Inc.*

Revamping of Emergency Broadcast System

The Emergency Broadcast System, or EBS, will soon give way to the Emergency Activation System, or EAS. The current EBS was instituted under President Kennedy in 1963 as a way of using telecommunications to alert the public to an emergency. This was a year after the Cuban missile crisis and its original intent was to allow the president to address the nation at a moment's notice in an emergency. Currently, stations put a test pattern or tone on the air and then announce that a test is under way. An eight-second, one-kilohertz tone signal follows. Finally, the audience is told that in the event of an actual emergency they would be given Civil Defense Instructions.

The current EBS relies on a daisy-chain notification system, where one station receives the warning and then sends it on to the next station. That means if one station's equipment fails, others may not get the warning. The new Emergency Activation System depends more heavily on an approach similar to the World Wide Web. In the new system no station relies on just one source to receive the broadcast warnings. Rather, digitally encoded signals will activate computers at radio and TV stations and download emergency warnings.

From the January 1997 *PARKing Ticket.*

FCC Web Site

The FCC's Office of Public Affairs recently announced the establishment of a new page on the Commission's Internet Web site that will provide worldwide access via the Internet to live and recorded audio broadcasts of selected FCC events. The Commission began by broadcasting its December (1996) meeting through a RealAudio link on the FCC's home page. This site will also include a schedule of events, a comment form and an E-mail address to solicit ideas on how to improve or add to its usability. The site is http://www.fcc.gov/realaudio/.

RE: Insurance Claim #KNEBSO4GON

I am writing in response to your request for additional information.

In Block No. 3 of the accident report form, I put "poor planning" as the cause of the accident. You said in your letter that I should explain more fully, and I trust that the following details will be sufficient.

I am an amateur radio operator. On the day of the accident, I was working alone on the top section of my new 80-foot antenna tower. When I had completed the work, I discovered that I had, over the course of several trips up the tower, brought up about 300 lbs of tools and spare hardware. Rather than carry the now unneeded tools and material down by hand, I decided to lower the items in a small barrel by using a pulley which, fortunately, was attached to the top of the tower.

Securing the rope at ground level, I went to the top of the tower and loaded the tools and materials into the barrel. Then I went back to the ground and untied the rope, holding it tightly to ensure a slow descent of the 300 lbs. of tools. You will note in Block No. 11 of the accident form that I weigh 155 lbs. Surprised at being suddenly yanked off the ground, I lost my presence of mind and forgot to let go of the rope. Needless to say, I proceeded at a rather rapid rate up the side of the tower. In the vicinity of the 40-foot level, I met the barrel coming down. This explains my fractured skull and broken collarbone. Slowed only slightly, I continued my rapid ascent, not stopping until the fingers of my right hand were two knuckles deep into the pulley.

Fortunately, by this time I had regained my presence of mind and was able to hold tightly to the rope in spite of my pain. At approximately the same time, however, the barrel hit the ground and the bottom fell out of it. Without the tools, the barrel now weighed 20 lbs.

I refer you again to my weight in Block No. 11. As you might imagine, I began an abrupt descent down the side of the tower. Around the 40-foot level, I met the barrel coming up. This accounts for the two fractured ankles and the lacerations of my legs and lower body. The encounter with the barrel slowed me enough to lessen my injuries when I fell onto the pile of tools, and fortunately only three vertebrae were cracked. I am sorry to report, however, that as I lay there on the tools, in pain, unable to stand, and watching the empty barrel 80 ft. above me, I again lost my presence of mind. I let go of the rope.

TNX, *ARNS Bulletin*, February 1997, with additional TNX to *RadioActive*Notes.*

70 Cm Band Loss in Guatemala

Hams have lost out to commercial users of the 70 cm band in Guatemala, and the cost could be interference to ham radio satellite operations worldwide. This is because Guatemala now intends to put commercial operations across the band—commercial signals that will probably include the 70 cm satellite subband.

Manfred Kolbe TG9IKE reports via the *AMSAT News Service* that on Monday, November 18, 1996, the *Diario de Centro America* published the new law regulating all telecommunications in Guatemala. Part of the law removes ham radio access from all frequencies above 146 MHz except for tiny slivers in the gigahertz region.

The new law was created by a commission from the state-owned telecommunications company GUATEL, which consulted the Radio Club of Guatemala about the project. The commission was quite astonished to learn that ham operators operate some 20 satellites for global communications, and even more so when Guatemalan hams supplied a list of amateur satellites with operating frequencies and modes. The existence of the Amateur Satellite Service was also brought to the attention of the CEO of GUATEL. Also told was the chairman of the committee of Congress in charge of the new Guatemalan telecommunications law. He was even presented IARU and ITU documentation.

But even with all of this documentation, the decision was made to run the hams off and turn the spectrum over to moneymaking operations. As a result, the 70 cm band in Guatemala, which is composed of the frequencies between 430 to 440 MHz has now been declared available for commercial use only.

And it's not only Guatemalan hams who will face problems because of the change. There is likely to be heavy interference to Amateur Satellite Service operations in Region 2 when the transponders on various hamsats pick up commercial signals and rebroadcast them on other bands. Even for low orbiting satellites this will affect an area in southern Canada, all of the USA, Mexico, Central and South America down to Chile and Argentina. Taking into account the future operations of the Phase 3D ham satellite, the situation may even get a lot worse.

Lifted from *SARA* (Socorro Amateur Radio Assn.) *News*, January 1997, with TNX to *Newsline Radio*, CBBS Edition #1008, 12/6/96.

NEVER SAY DIE
Continued from page 83

pour. Since I had to open and answer them all, it was a pour for me.

But why am I the only one out there getting on talk radio and promoting amateur radio? There are thousands of talk shows and you're just sitting there like a lump on a stump, not doing your bit. Look, the ARRL has shown pretty clearly that *they're* not going to do anything to help get the public interested in amateur radio. The few promotions I've seen have been feel-good stuff for hams, not information for the public. The public doesn't remember a lot of what CB is,

much less has ever heard of ham radio.

Yes, I know all the excuses. Rationalizations to explain why nothing is being done. Sure, kids are into the Internet. They're into computer games. Yatata yatata. Kids have always been interested in lots of things, but that didn't stop them from getting hooked on ham radio. I somehow managed to get involved with hamming even though I was also involved with dating, roller skating, reading books, photography (I spent endless hours in the school darkroom), singing (with the St. Paul's choristers, the Erasmus Hall Choral Club, and the Philharmonic Choir of Brooklyn), seeing every movie that came out, the Boy Scouts, and so on.

In high school I not only rehearsed every day with the Choral Club, I belonged to the Savoyards, where we put on Gilbert & Sullivan operettas, the book club, the camera club, and the radio club. I had plenty to do without amateur radio, but there I was, busily putting together ham and audio equipment in my workshop. I did that for years.

So don't whine to me about how kids are too busy today for amateur radio. What we need is a selling job. We're not pushing the product, so we're going to go out of business. You can't sell any product unless the public knows about it. That means visibility. National and local visibility. Are your ham club meetings announced in the local papers and on the community radio and TV announcements? How about posters in the local schools? On any local bulletin boards. On the Internet, for that matter? In Peterborough the local A&P has a bulletin board near the store exit.

How about getting after your ARRL director to get the League to do some national promotion? When is the last time you saw a story about the fun and adventure of amateur radio in a national magazine? Or a local paper, for that matter? Yes, I know, I'm repeating myself. Well, I *have* to, since you haven't done anything to make things change. And I'm going to keep after you to lean on the directors, to do all of the promotion you can locally, and to get your more talkative members into your local schools to acquaint the 5th graders with what we have to offer. Otherwise you're going to have to make do with CB fallout. That what you want?

Plenty of big organizations have blundered themselves out of business, so the ARRL could easily be blown away. The National Computer Congress ran the biggest show in the computer industry, often drawing around 100,000 attendees, packing New York, Las Vegas, Dallas, Atlanta and Chicago hotels. But they ignored the personal computer and were wiped out.

We need to get millions of kids interested in high-tech careers, and amateur radio is one of the easiest ways of doing that—but only if they're made aware that the hobby exists.

The people writing to me are subscribing to *73*, but they also want to know what books I can recommend they read to understand the fundamentals of electricity and radio. I've asked you to let me know which are the best books you've found so I can let them know. I haven't heard from you yet. Tsk.

Parenting

The most important skill we can build is in parenting. The one mark most of us leave behind is our children. Unfortunately, the parenting skill is no more intuitive than any other. And since this is probably the most important thing you're going to do in your life, the more you can learn about this skill the better. After all, when you make mistakes with your kids you are usually making permanent mistakes which will to some degree cripple them, or at least rob them of their full potential.

The cover feature on the February 3, 1997, edition of *Time*

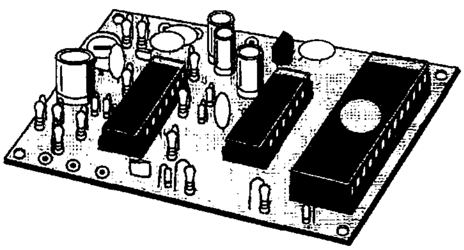
New Products



New Hamtronics CWID Module

Ever since Hamtronics, Inc., introduced its slick low-power CMOS COR-4 module several years ago, customers have asked if they could get just the CWID part of the unit. They had different applications in mind: not just amateur repeaters, but beacon stations, commercial and public safety 2-way radio base stations, broadcast satellite uplinks—and so on.

Here it is: The new CWID-2 module features small size, ease of assembly and maintenance, versatility, and a thorough manual which describes how to take advantage of all the available options.

The CWID-2 uses all CMOS logic and operates on 7-15V at only 3 mA. It's easy to fit into existing enclosures because it's only 1-3/4 x 3-1/8 inches. The factory-programmed EPROM saves assembly time and allows longer messages than did their earlier diode-matrix type CWID module—up to 200 characters. The CWID-2 can also be set to repeat a message continuously for beacon operation.

For more details, write Hamtronics, Inc., 65-F Moul Road, Hilton NY 14468-9535. Phone (716) 392-9430 or FAX (716) 392-9420 and ask for a complete catalog.

Stop That Interference!

Don't let strong radio signals ruin the game (or sitcom, or soap) for you. Use the MFJ-711 high pass TVI filter between your cable and VCR or TV and wipe out TVI coming from broadcast, commercial, two-way, amateur and CB radios operating below 30 MHz.

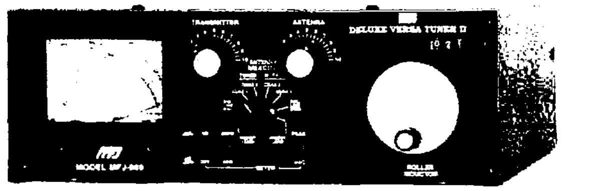
The MFJ-711 is protected by MFJ's famous "No Matter What™" one-year unconditional warranty, and it's only $24.95! See your dealer, or contact MFJ Enterprises, Inc., at 300 Industrial Park Road, Starkville MS 39759; phone (601) 323-5869 or FAX (601) 323-6551; order by calling toll-free (800) 647-1800.

It's a perfect gift for anyone who's tired of watching a messy TV screen—think Father's or Mother's Day—so use your highlighter and leave this copy of *73* in a prominent place!

191 AM Radio Log

The National Radio Club's 17th edition of their AM Radio Log is now available. Its 312 pages list the US and Canadian AM broadcast stations by frequency from 530-1660 kHz, with a cross reference by call letters and city. The listing includes the call, address, format, networks, phone, day and night powers, antenna, time zone, and slogans. With 191 listed stations on 1230 kHz, a person could make a career out of logging everything on one frequency. The list comes on 8-1/2" x 11" paper, punched for a binder. The club also has lists available of Latin American, European, and all other stations. Box 164, Mannsville NY 13661.

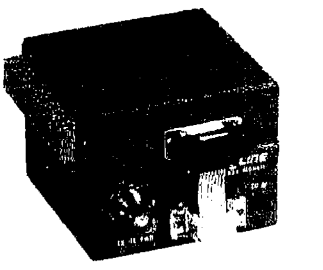
Absolute Minimum SWR



MFJ presents the world's only 300W AirCore™ roller inductor antenna tuner—the MFJ-969! It has all the great features of the MFJ-949E, plus the widest matching range of any full-featured antenna tuner and continuous 6m through 160m coverage. MFJ's AirCore roller inductor, a three-digit turns counter and spinner knob gives owners of the MFJ-969 exact inductance control; you get absolute minimum SWR, something you just can't get with a tapped inductor.

MFJ's QRM-Free Pre-Tune™ lets you pre-tune your MFJ-969 off the air into a built-in dummy load without causing QRM, making your actual antenna tuning faster and easier. There are scads of other features, and they all fit neatly into a scratch-proof black box less than a foot square—and it's only $179.95. For more information or the name of your nearest dealer, contact MFJ Enterprises, Inc., at 300 Industrial Park Road, Starkville MS 39759; call (601) 323-5869; FAX (601) 323-6551; visit the Web site at http://mfjenterprises.com; or order toll-free at (800) 647-1800. Check it out. Absolutely.

New Skyline-RTU

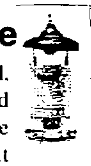


RF Neulink introduces the new Skyline-RTU synthesized VHF transceiver, designed to make remote data control reliable and simple. Each RTU is a fully integrated subsystem that includes a transceiver, RS-232 modem interface and a digital/analog I/O board, all in a 3" x 3" x 2.5" steel enclosure.

The radio modem platform is the NEULINK 9600V, a high-speed 9.6 kBps 2-watt transceiver modem. Up to 64 channels can be programmed into internal memory. With its 65,000 unique ID codes, this synthesized VHF modem can be configured for point-to-point and point-to-multipoint networks. Frequencies available are 136-174 MHz, 218-230 MHz, and 260-280 MHz.

For additional information contact RF Neulink, 7610 Miramar Rd., San Diego CA 92126. Call (800) 233-1728 or (619) 549-6340; FAX (619) 549-6345; E-mail: rfneulink@aol.com

From Russia, with Low Noise



Svetlana Electron Devices, Inc., announces its EF86/6267 audio small-signal pentode. Manufactured in St. Petersburg, Russia, it's perfect for first gain stage in phono, guitar, or microphone preamps: The voltage gain in pentode connection is greater than 400. The EF86/6267 is designed for low noise, low microphonics, and low heater-cathode hum induction.

It's internally shielded, and the solid metal shield canister improves structure rigidity—you'll find it superior to the screen shields used in older versions of EF86. To learn more about other features of the EF86/6267, contact Svetlana at 3000 Alpine Road, Portola Valley CA 94028. Phone (415) 233-0429 or FAX (415) 233-0439.

PROPAGATION

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

As this is being prepared (late January), the solar flux is still at a *very* low level (75) and there is no sign of improvement in propagation conditions that would lead to encouraging news for DXers in the immediate future. Conditions in April are likely to provide GOOD days on the 7th-10th, 14th, 15th and 22nd. POOR days are likely to be the 1st, 2nd, 18th, 19th, and 26th-29th. FAIR days are expected on the 4th, 5th and 24th. Days trending *adversely:* 11th, 12th, 17th, 25th, and 30th. Days trending *favorably:* 3rd, 6th, 13th, 20th, and 21st.

There is a possibility of very upset geophysical conditions on Earth on the 18th and 19th and the 26th through the 29th. These could be weather/atmospheric- or magnetic/ionospheric-related, or possibly combinations of these effects. As you can see, it is an interesting mix: five days trending adversely and five days trending favorably. There are seven Good days, three Fair days, and eight Poor days, so April represents an almost 50-50 split between favorable and unfavorable conditions. Therefore, you will have to keep a sharp lookout to make the best of opportunities, and continually monitor WWV at 18 minutes past any hour for the latest updates on magnetic field, ionospheric and solar flux values as they change—to either help or hinder.

10-12 meters

Generally Poor, except for occasional transequatorial propagation with F2 openings on the best days—most likely South and Central America.

15-17 meters

DX to Africa and Latin America on the Good days possible, with short-skip out to about 1,000 miles or so in the U.S.

20 meters

Your best band for DX openings around the world from dawn to dark, and openings to the Southern Hemisphere after dark in evening hours. You can expect excellent short-skip during the daytime to 2,500 miles or so.

30-40 meters

These bands ought to be open for DX from just before sunset to just after sunrise. Signals from the east should peak until midnight, and after midnight to other areas. Daylight short-skip of about 500 miles will be possible, and nighttime short-skip to 1,500 miles or more will be available.

80 meters

Occasional DX to various areas of the world should be possible between sunset and sunrise when QRN levels permit on Good (G) days (see calendar), as well as short-skip during hours of darkness to 1,500 miles or more.

160 meters

This band ought to begin to come alive again during the hours of darkness when QRN permits. Try the days marked (G) on the calendar for best results. DX toward the east until midnight, and to other areas afterwards until dawn. Short-skip to 1,500 miles will prevail when the band is quiet.

HAM HELP

We are happy to provide Ham Help free on a space-available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double-spaced, on a full 8-1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully. A 1, for example, can be misread as the letters I, i, I, or even the number 7. Specifically mention that your message is for the Ham Help column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Needed: Owner's manual, schematic diagram, or service manual for a Bearcat Model BC-8 scanner. Please contact *Glenn Torres KB5AYO, 584 Central Ave., Reserve LA 70084.*

NEVER SAY DIE

Continued from page 85

had to do with educating babies. It pointed out that there are windows of opportunity for kids to develop their brains. If they don't get the right stimulus at the right time, their brains do not develop normally and never will.

When I learned to horseback ride I found that virtually every intuitive response was wrong. Ditto when I learned to ski. Well, the same goes for bringing up kids, so if you don't get busy and start reading before you get involved with the most important project of your life, you are going to do irreparable damage.

The damage—permanent damage—can start even before conception. I've a number of really great books on this subject on my list of books you're crazy if you don't read, and I'll be adding a few more. Eventually I hope to have the time to write a book on the subject, but I'm not sure there are enough people who care how their kids turn out to make it worth my time.

How early should you start reading to your child? How about before birth? Music, too. One book I recommend explains how you can teach your child over a hundred words before it is born. Will your baby have heard Beethoven's and Sibelius' symphonies a bunch of times before being born? Rock music? Not if you've read what playing it does to plant growth! Yes, there's a book I recommend on that, too.

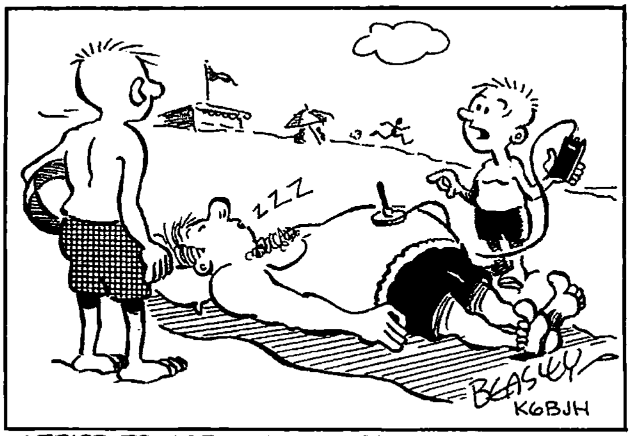
If you don't do anything to change our school system radically you're going to want to find a private school, and probably get your kid started at two or three years of age. Something like the Sudbury Valley School, with Montessori ideas thrown in.

Well, enough on that for now.

Eating It Raw

When I mentioned on the Art Bell show that I've shifted to a mostly raw food diet, and that I've found a great combo is to chop up (I use the Cuisinart) raw broccoli, cauliflower, and carrots into small crunchy bits, and then add some of my coleslaw dressing, I got a bunch of requests for the dressing recipe. In case you missed it a few months ago, it's simple and full of healthy stuff. Mostly. Take five parts plain yogurt, two parts apple cider vinegar, two parts extra-virgin olive oil, one part honey, one part light mayonnaise, salt and pepper to taste, and lace generously with celery seeds. My, it's good! It also makes a good dip for raw veggies. You can chop up cabbage and you've got coleslaw. It's a sauce, a dressing, and a dip.

73 wants your feedback... we've been improving *73* for the past months with more articles, easier reading type, etc. And honestly, we *need* your feedback (in detail) if you have any critique either for or against the subtle changes that we've made. We know we can't please everyone everytime, but if you tell us what you want *73* to be, we'll at least try to head in the direction for further "improvements" that might be most appealing to you. Thanks.



I TRIED TO USE HIM AS A PARABOLIC REFLECTOR, BUT I THINK HE'S CURVED THE WRONG WAY !!

Never say die

Wayne Green W2NSD/1

220 Pffft?

I am pleased to report that every club newsletter I've seen that mentioned the potential loss of 144 and 450 MHz to the Low Earth Orbit (LEO) companies has 100% supported the ARRL position. I like to see solidarity like that, no matter how wrong-headed. Obviously none of the newsletter editors has read my editorial views on this subject, nor have any of their club members tuned them in. Figures.

For any newcomers, and for readers with particularly short memories, I reported that when the LEOs decided to go for our 144 and 450 bands for their satellite use, the ARRL met with them and, instead of trying to reason or come to some compromise, the League representatives threatened to have their members make life miserable for the LEOs if they didn't stop trying to take our bands.

The LEO reaction was predictable. It was the same as I would have reacted. The LEO group got mad and any chance of their backing down was blown. So I was sort of amused to read that the LEOs have added our 220 MHz band to their list. Maybe, if our paper dragon blusters some more, they'll add our 1296 MHz band to their list. Hey, it's worth a try.

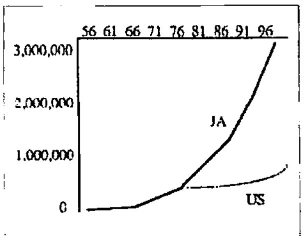

Fig. 1. Comparison of growth of amateur licenses in Japan and the U.S.

Let's look at the game board. It's a map of Washington and the goal is influencing Congress. On one side we see an army of well-heeled lobbyists surrounding the appropriate committee members, waving wads of "reelection" cash at them—on the other, an old ARRL lobbyist ham sitting there with no budget, wondering what in hell he can do.

Of course, if we had three million hams, as they do in Japan (with half our population), that would be another story.

How serious are the LEO guys? Their plan is to provide a service which will virtually eliminate the need for wires or coax into businesses and the home. Over three quarters of all the satellites planned to be orbited in the next few years are for this service. We're talking pocket telephones which will let us talk to anyone on earth. We're talking high-speed digital data and video. And all this means bandwidth (spectrum), which has to come from somewhere, and guess which "service" has the least political clout to protect its spectrum?

Who needs emergency ham communications when there are hundreds of low earth orbit satellites to relay voice, data and video to anywhere on earth? Tornadoes, earthquakes and other disasters aren't going to affect this system. So what other ham services does that leave, for us to cite as a reason for our being allocated badly-needed spectrum? We're up in the trillion dollar range.

Sure, in WWII days the ham population helped save the country's bacon by providing 40,000 radio and electronics technicians and radio operators. And before the ARRL gutted our growth with their monumentally stupid push to expand membership 30 years ago we hams were busy experimenting and pioneering new modes of communications. We were providing a very valuable service in exchange for our ham bands. Worse, if our growth hadn't been suddenly stopped, we *would* have around five or six million hams today, and most of 'em would be youngsters bent on high-tech careers, just as it was before the 1965 catastrophe.

It's going to take millions of technicians, engineers, and scientists to design, build, sell, install, operate, and service the coming world communications network. And most of these chaps are *not* going to be Americans. Not with our school system.

So can you see why the LEO group, with billions of dollars at stake, is snickering over the ARRL power play? Or why I call the League a paper dragon?

Instead of urging the hundreds of ARRL member clubs to write nasty letters to the LEO group, we might stand a better chance of survival if the clubs (a) started electing members to their state House and Senate so we'd start having some political clout, and (b) push their local school boards to institute an eight-year course in the fundamentals of electricity, computers, and communications for any student interested in being able to cope with the needs of the 21st century work force. Instead they're trying to fight an unwinnable battle which could hasten our destruction.

But I'll bet I won't see any hint of this scenario in any ham club newsletters.

On the bright side, I don't see any commercial needs for our HF bands, so I'm waiting anxiously for the sun spots to return and propagation to pick up. Amateur radio has provided me with a lifetime of enjoyment, learning and adventure. If we blow this one, I'm going to miss it.

Who are these LEO companies that the League has threatened? Well, there's Teledesic, which is planning to loft 840 satellites. That's Bill Gates and Craig McCaw. There's Iridium with 66 satellites and backed by Motorola, Raytheon, Lockheed Martin, Sprint, and 13 others. Globalstar plans 48 satellites, backed by Loral Space and Communications and Qualcomm Inc. Orbcomm plans 28 satellites, backed by Orbital Sciences and Teleglobe. That adds up to around 1,000 more satellites.

The biggest, Teledesic, will be an "Internet in the sky" and aims to replace the need for fiberoptic cable systems. These new services will allow hand-held phones, pagers, remote phones, the keeping track of trucks and planes, the remote monitoring of anything, FAX, etc. And that's what the 21st century is going to be like. We'll get used to it.

East vs. West

Take a look at the graph. It compares the growth of amateur licenses in Japan and the U.S. in recent years. The American no-code ticket resulted in an uptick of U.S. licenses. But look at what's been going on in Japan. While we have around 700,000 licensed hams on the books, Japan has now over three million! And that's with *half* our population.

One sees the difference just by looking at the Japanese ham magazine. It's well over 400 pages a month and packed with interesting-looking construction projects and technical articles. A couple of generations ago we had a section of Manhattan with a half dozen or so ham stores all in the Cortlandt Street area. Boy, did I haunt those stores. In Tokyo I just couldn't get over the Akihabara section of town where there are hundreds of stores selling electronic parts, all swarming with Japanese youngsters buying 'em by the bags full. We don't have anything like Cortlandt Street anywhere in our country anymore—with Cy W2BNW selling surplus gear, Blan The Radio Man, Harrison Radio, and so on. Sigh.

With ham clubs in every school in Japan it's no wonder they have so many hams. And, as used to happen here, a high

LETTERS

From the Ham Shack

Ken Dumminger N8VWZ, Fremont OH. (See April's "Never Say Die.") Recently, Kenwood announced that they were changing their dealer structure to sell through more outlets. The amateur radio community was in an uproar regarding this policy. I read messages on packet that indicated that Kenwood would be selling radios at truck stops, etc. The economics is quite simple. If you are a manufacturer and your products aren't selling then you have to find new arenas in which to sell before you go out of business. When you connect to these manufacturers' Web pages you find that many of them have diversified and are selling to other markets (e.g., marine, etc.).

What I am trying to say is that in the foreseeable future we in the ham community are going to be told that our spectrum is worth a lot of money to the general public so the FCC and Congress are going to sell it to the highest bidder. Based on recent sales of spectrum by the FCC, the commercial radio community is willing to pay large sums of money to get this spectrum. An example of this is what has happened to the broadcast industry. They negotiated with Congress to lock in their spectrum for the purpose of the new digital HD TV broadcast. Recently it was announced that NBC was purchasing new transmitters for their future and the other networks are doing the same.

This leaves two other organizations that have a large amount of spectrum: the military and the amateur community. I am sure that the military isn't going to give up any spectrum, or if they do it will be minimal. This leaves only the amateur spectrum. In the past we haven't paid a cent for our spectrum, but Congress and the FCC have a wealth of buyers at their doorstep with new technologies. Where do you think they are going to look for new spectrum? It doesn't take much to figure this one out.

We as a lobby group are losing our position. The drop in membership of this fraternity is becoming alarming. We are not licensing new hams in other than Technician Class. We are hung up on the "code issue" to the point that we are willing to lose everything rather than adjust to the new markets. I am 50 years old. I have been working with my local club to get membership. Bottom line is why do I want to become a ham and pay big bucks for equipment when I can communicate either with cell phones, the Internet, or inexpensive GRS radios from Radio Shack. Young people see no need for the hobby. Older people are driving up and down the highway using cell phones and can get on the Internet for the price of a meal and can connect to anyone or anything. Even the public service people are getting so sophisticated that their need for the ham community for emergencies and public safety is becoming minimal. I recently heard a Red Cross official state that in their emergency plan they have decided to use cell phones rather than hams. While we can debate this issue for quite a long time, the simple fact is the public is going around us.

We are spending so much energy regarding classes of license and the importance of code that we have convinced the public that it is so difficult to participate in amateur radio that most don't want to get involved. Elmering is almost a lost art. Most of the interested people cannot even find an Elmer. They just go buy a book and take the test. Code, for the most part, is only used to keep people out of the hobby rather than bring them in. Older hams are reluctant to give on this issue because they have the bands and enjoy operating with less interference. The use of Morse Code for all practical purposes is gone. Most ships don't even have radio rooms. The military dropped the code years ago. I could go on and on, but the bottom line is the fact that very little licensing is being done on the level that we need to justify the spectrum. "If you snooze you lose," seems to be the position at the FCC.

The FCC is even looking at their staff. You are seeing announcements of people who are leaving the FCC to take jobs in the private sector. We are seeing the requirement for paperwork dropping. No renewal notices, instant licensing, etc. Even the testing has gone VE. What is going on? Simply, the FCC is an organization that is going to collect fees and sell spectrum. The new people at the FCC are interested in the bottom line. The technical aspect is going or already gone.

In closing, I would like to say that I enjoy amateur radio. I enjoy the activities and the technology. However, am I going to spend months learning code so that I can get permission to use the low bands? Why should I? Amateur radio is a hobby and I don't have the time to spend. I have a business and a family, plus I am involved in my community. Most of this is more important than getting a higher class license. I have no problem taking a test as to what I know... I have typing skills and a computer which is very fast. Why can't I use that and take a typing test rather than learn to reinvent the wheel? Why aren't the astronauts required to learn code to be able to fly our space ships?!

Troublemaker... Wayne.

Mike Miller WA8YKN, Richmond IN. I read the interesting report from George Bergstrom of Rancho Cordova, California, in the Letters column of the March issue, which included George's circuit for his "blood purifier." While this perhaps overly-complex circuit will probably work fine and give the same results as the other methods used to produce the same output, I feel I should point out that it violates the first rule of bioelectric experimentation. It is important that *any* device which is attached to the body via low-resistance electrodes be *battery powered!* There should be no potential anywhere in the circuit higher than that which is needed to achieve the required current flow. The Bergstrom circuit is operated from the 120-volt AC power line. There is always the possibility that someone may improperly wire the circuit, which could lead to a tragedy. Even if everything is properly connected, you should keep in mind that your *life* depends on the integrity of the transformer wire insulation every time you connect it to your body! Electrocuting experimental subjects can generate bad press. There are politicians who are waiting to do the bidding of the drug lobbyists, so let's not give them a reason we can easily avoid.

Mike's right. Batteries are cheap and lawsuits aren't. How many of you would bet your life on how well your AC line is grounded?... Wayne.

Scott Rorex KI5FC, Imboden AR. In your March editorial you asked that we let you know if we are interested in doing anything about the young ham situation. I am interested. This is what has happened here so far. Our children are seven and nine years old. I agree with your thinking about education and have tried for a couple of years to get ham radio and other technology incorporated into the existing school here.

Generally I have found the administration and some teachers interested, but the bureaucracy pretty much has tied their hands. Next, I got some extra copies of *Declare War, Dumbing Us Down, Smart Schools - Smart Kids*, and *If You Want To Be Rich and Happy, Don't Go To School*. I've handed these out to the superintendent and some teachers, principals, board members and other parents.

Your mentioning the Sudbury Valley School is just what I was looking for. When I read that I went to see if they had a Web page. They have a great one, with a list of about 20 similar schools around the world and links to several of the other schools (www.sudval.org). Please check it out. I believe that simply by making parents and students aware of the Web pages and then seeing what is on those Web pages, the bureaucracy won't be able to stop them. I see amateur radio as a perfect fit in a school like Sudbury Valley.

Thanks for helping wake us up.

Good show, but Scott, we need irritants like you in every town... Wayne.

Lester Warriner WA7HAM, Prosser WA. Please check out the ad on page 148 (March *QST*) for the ARRL Amateur Radio License Weekend Technician Class. $159 for 20 hours of class, two books and a binder. That leaves a lot for the instructor's pocket. Who said this hobby was non-commercial? And non-profit? Is Elmer really dead? Lay some green on my hand and I'll help you into this great hobby of ours! But don't expect me to do it for free. I would have thought an ARRL-sponsored class would be free except for texts. That's how classes are conducted out here. In the ARRL's official meeting they were crying about the technical incompetence of the present day ham. What technical information can be given in 20 hours? Who's kidding whom? The sickness is spreading.

That's a bunch of carp... Wayne.

Jim Ginnta WB3HDA, West Chester PA. I ordered a Bioelectrifier kit and put it together. I assumed it was just another gadget, so I let it sit on my workbench without trying it. I was sure I'd wasted my money. Then a few days ago, I woke up with a toothache. I decided to try the Bioelectrifier and see what effect it might have. I used it for 20 minutes and the toothache was gone! I don't believe this was a coincidence. I've had toothaches before and I've never known one to simply go away in 20 minutes. The Bioelectrifier works!

NEVER SAY DIE

Continued from page 4

percentage of their kids go on into high-tech careers as technicians, engineers and scientists. When I visit the research and development labs in Japan I'm greeted by hams at every turn. So we're surrounded by Icom, Yaesu, Kenwood, Sony, Hitachi, Toshiba, Aiwa, Pioneer, Sansui, Alinco, Azden, JRC, Standard, Onkyo, etc.

Of the 700,000 American hams listed in the *Callbook*, I'll bet we don't have 100,000 still active on our HF bands. The FCC keeps us on the books for ten years, even if we've dropped dead or dropped out, so that official number is seriously inflated.

Will you complain that I'm ARRL-bashing if I suggest that perhaps our faith in the League's leadership may be misplaced? Any corporation that produced such a disgraceful performance—such a loss of customer base compared to the competition—would have their board of directors and officers replaced by better performers. The ARRL directors aren't asleep, they're dead! And not only is the hobby hurting as a result, but so is our country. If this is ARRL-bashing, who else is there to bash? It's our only national organization, so we're totally dependent on the quality of its performance for the life of our hobby—and if you feel it's unfair to hold the board of directors responsible for the corporation's performance, then who do you feel is responsible? You have the proof and it is undeniable. The Japanese are kicking the s...tuffing out of us.

With over three million hams, do you think the Japanese counterpart of our FCC is going to auction off their well-occupied UHF and microwave ham bands? Not a chance.

So what can you do? I explained that a long time ago and it went in one eyeball and out the other. Get some young ham with guts in your club to run for director: get behind him with a vengeance, and help flush the old-timers out of Newington. Let's get some life into our hobby. Let's see some double-digit growth again.

Yes, I've heard all the feeble excuses. Whine, whine, the kids today, etc. Well, the Japanese kids today are going for ham radio in one hellaceous way, and they have the same toys we do. In fact, that's where most of our toys are designed and built.

I suppose I should be nice and play it cool so I don't screw up

Help Wanted: Dayton Youth Forum

New York City—Educator Carole Perry WB2MGP will be moderating the popular Dayton Youth Forum on May 17th. She is looking for articulate, enthusiastic young people (8-18 years of age) who would like to be presenters. Please call Carole at (718) 761-5733 as soon as possible.

Congress Orders Reallocation of 13-cm Amateur Radio Spectrum

The 104th Congress adjourned October 3, 1996, the day after the Senate concluded its business. Much of the important legislation in the final hours was wrapped into the 2,000-page omnibus budget resolution, HR 4278.

Unfortunately, the following language was included in this bill—now Public Law 104-208. This bill was signed into law by President Clinton on October 4, 1996. Here is the text of the legislation:

Title III—Spectrum Provisions

Sec 3001. Competitive Bidding for Spectrum

(a) Commission Obligation to Make Additional Spectrum Available—

The Federal Communications Commission shall—

(1) reallocate the use of frequencies at 2305–2320 megahertz and 2345–2360 megahertz to wireless services that are consistent with International agreement concerning spectrum allocations; and

(2) assign the use of such frequencies by competitive bidding pursuant to section 309(j) of the *Communications Act of 1934* (47 USC 309(j)).

(b) Additional Requirements—

In making the bands of frequencies described in subsection (a) available for competitive bidding, the Commission shall—

(1) seek to promote the most efficient use of the spectrum; and

(2) take into account the needs of public safety radio serviced.

(c) Expedited Procedures—

The commission shall commence the competitive bidding for the assignment of the frequencies described in subsection (a) (l) no later than April 15, 1997. The rule governing such frequencies shall be effective immediately upon publication in the *Federal Register...*

(d) Deadline for Collection—

The Commission shall conduct the competitive bidding under subsection (a)(2) in a manner that ensures that all proceeds of the bidding are deposited in accordance with section 309(j)(8) of the *Communications Act of 1934* not later than September 30. 1997.

What does this language mean? On the surface it appears to mean that Congress and President Clinton have authorized the 2305 to 2310 MHz segment of our Amateur Band to be transferred into the pool for auction and competitive bidding to commercial interests, and that it will be removed from the Amateur Radio Service. That still leaves the 2300–2305 MHz segment for Amateur operations... at least for the moment. At this time no one knows exactly when the 2305 to 2320 MHz band will be auctioned and if the 2305 to 2310 MHz segment will be removed from Amateur use. The new law requires the competitive bidding to begin within six months.

According to Brad Wyatt K6WR, ARRL Pacific Division Director, the League had worked with the key Congressional members to avoid this outcome—and hoped that they would be successful. During the final two weeks of the 104th Congressional session, "...the ARRL repeatedly submitted written and verbal statements to the key Congressmen asking that Congress stay out of the direct spectrum allocation business as it has in the past." But, it was to no avail.

Congress has now directed that the 13-cm spectrum should be quickly reassigned as part of the budget and deficit reduction process. In short, the radio spectrum represents "big dollars" to the US treasury. Commercial interests have already paid more than $20 billion to the government in recently held spectrum auctions. And you can certainly expect this trend to continue. "Sell everything in sight," continues to be the policy...

TNX to *The Repeater*, November 1996, which copied it from the *W5YI Report* dated Nov. 1, 1996.

Worked All Parish Award

Since Louisiana is the only state in the US that uses parishes as its primary political subdivision (instead of counties or boroughs) and Baton Rouge is the capital city of Louisiana, the Baton Rouge ARC has decided to sponsor a Worked All Parish Award. This award is being offered as an effort to stimulate activity on the high frequency bands, and will include an attractive certificate suitable for framing.

Copies of the Rules and Requirements are available by sending an SASE to the BRARC Awards Committee at P.O. Box 4004, Baton Rouge LA 70821.

TNX L. Wayne Gordon K5EOA, President, BRARC.

Phase 3-D Launch Now Set for July, 1997

Silver Spring MD (AMSAT News Service)—A published report released on Tuesday, December 17th by the European Space Agency (ESA) has shed new light on the planned launch date for AMSAT's phase 3-D international satellite aboard the next flight of the Ariane 5 booster, Ariane 502.

Following a plan of action set in motion last September among ESA, the French Space Agency (CNES) and the firms concerned in building the rocket, a detailed timetable for operations leading up to Ariane flight 502 has now been established by these organizations.

ESA reports that, while each individual operation will require very close analysis, the Ariane 502 launch is now scheduled for early July. The last qualification launch of the Ariane 5, Ariane 503, managed by ArianeSpace, has now been scheduled for November 1997.

AMSAT-NA President Bill Tynan W3XO welcomed the news, saying that, "It gives us a definite goal to shoot for in our preparations of the Phase 3-D spacecraft; however, every month the launch is pushed back means more funds are needed." Bill noted that a letter is currently going out to all AMSAT-NA members asking for additional contributions to the project. He emphasized that, "It is particularly important to the successful completion and launch of Phase 3-D that recipients of this letter respond as generously as they can."

AMSAT is a not-for-profit, 501(C)(3) educational and scientific organization that was first chartered in Washington DC, USA. Its objectives include promoting space research and communications by building, launching and controlling Amateur Radio spacecraft. Since its founding, over 25 years ago, many other like-minded organizations have been formed around the world to pursue the same goals and who now also bear the AMSAT name. Often acting together, these groups have used predominantly volunteer labor and donated resources to design, construct and, with the added assistance of government and commercial space agencies, successfully launch over two dozen Amateur Radio communications satellites into Earth orbit.

The Phase 3-D satellite, now under construction with the help of over a dozen AMSAT groups on five continents, will be the largest, most complex, and most expensive Amateur Radio satellite ever built.

Hams Want Morse Code

The numbers are in, and by a wide margin hams say that they want the Morse code to stay. In a recent survey conducted by the American Radio Relay League, amateurs have made their feelings known. Sixty-two percent of ARRL members polled

said yes to keeping the code, while thirty percent said no. Of all amateurs polled, members and nonmembers alike, fifty-four percent said yes to keeping the code, while thirty-seven percent said no. In this era of the popular No-Code Tech license, amateurs say no to the total no-code licensing.

The bottom line: In months past, some high-ranking officials have publicly hinted that the ARRL might not be opposed to expansion of privileges for no-code hams. As a result of this survey, when the League goes to WRC '99, it will have to stand its ground. It will be forced to say no to those administrations whose telecommunications leaders say that it's time to delete the Morse code as a testing requirement for getting ham radio voice operating privileges on bands below 30 MHz.

FCC Exams 2001?

Considering the general direction in which Amateur Radio seems to be heading and the climate that exists at the ARRL and FCC, I propose the following to be used as the official examination form by the year 2001...

FCC Examination Form For All Classes of Amateur Radio Operation—Jan. 1, 2001. Pick one or more of the answers as appropriate.

1) A "ham" is:

a. A delectable dish served for Christmas or with eggs for breakfast.

b. An uplifting phrase found in operations manuals for Japanese amateur equipment, meaning, "'H'onorable 'AM'erican," usually applied to the operators of said equipment.

2) A "rig" is:

a. A device used to dig wells, usually for water, but if you are lucky, perhaps for oil.

b. A device used to send electrical signals around the world. Archaic definition: "used to communicate with CW, RTTY, AM, or SSB."

Note: Since communication has long since ceased to be an objective of amateur radio, we at the FCC will not consider either answer to be incorrect. This is a freebie, not a trick question.

3) An "antenna" is:

a. A wire strung between the rafters in your attic.

b. A "flagpole" with a strange black box attached to the base.

c. A large array of tubing, wire and insulating material held from 50 to 200 feet in the air by a device called a "tower." Due to widespread ordinances, these are extremely rare, and found only in the remote corners of the desert Southwest.

4) "TVI" is:

a. Any form of interference whatsoever that is blamed on the operation of an amateur radio station. This can occur whether the station is on the air or not.

b. An abbreviation for the Tennessee Valley Inquisition, a fierce battle for tower rights that took place in the late 1990s.

5) "Guy" is:

a. A person you meet on the street and ask about the time, as in "Hey, Guy, what time is it?"

b. A wire used to hold up a tower in winds of 25 mph or less. Its use is considered to be optional by most amateur operators.

6) "Ground" is:

a. What a tower crashes into when the winds reach 30 mph or more.

b. What keeps Japan from being Line of Sight from here in the good ole U.S. of A.!

7) "Packet" is:

a. A grand experiment in digital communications that started in the early 1980s but ground to a halt because of too much infighting among SYSOPS.

b. Something you put your letters into when you really want the message to get where it is supposed to go. Stamps are applied to the outside of this packet and in a few days it arrives at its destination. Just like magic!

8) A "computer" is:

a. A device that has lured potential amateur radio operators away from the hobby by the thousands.

b. An enormous waste of time and energy, but, like women, "Ya can't live with them, ya can't live without them!"

9) A "printer" is:

a. Someone who works for the newspaper.

b. A device attached to a computer to accurately translate the tones received from the sending station into all the typos, misspellings and grammatical errors as they were originally entered by the operator.

10) "Electronics" is:

a. A mystical art that no one understands anyway, so why try to define it?

b. All of the above.

c. None of the above.

Congratulations! If you gave any answer at all to 70% of the questions above, you are worthy of becoming an amateur radio operator. Just fill out the form on the other side of this exam and send it in to the FCC offices shown at the bottom of the form.

TNX *Q-Fiver*, January 1997, who got it from *KI4QJ BBS*, who got it from Jim Stanicek AG3Y, who hopes that none of the above will be true in 2001!

FCC Plan Would Ease International Operating

The FCC has proposed amending the Amateur Radio rules to make it easier for hams holding a European Conference of Postal and Telecommunication Administration (CEPT) radio-amateur license or an International Amateur Radio Permit (IARP) from certain countries in Europe and the Americas to operate during short visits to the US. If finally approved, hams would be able to operate for short periods in participating countries without first obtaining another license or permit from the host country.

The FCC says the arrangement is intended to make it easier for US hams to operate stations temporarily in several countries in Europe, Central and South America. Likewise, hams from those countries would be allowed to operate stations in places where the FCC regulates ham radio. "We believe that US participation in both the CEPT agreement and the CITEL/Amateur Convention would benefit US amateur operators who travel to Europe and to the Americas," the FCC said in its discussion of WT Docket 96-188.

Operating authority by CEPT or IARP holders in the US would be for "up to 180 days within the preceding five years." The two classes of CEPT licenses would correspond either to Amateur Extra or Technician class. Resident aliens or US citizens could not operate in the US under a CEPT license or IARP.

Last year, ARRL petitioned the FCC to implement the CITEL/Amateur Convention. The League also asked the Commission to acknowledge arrangements to be made between the ARRL and the Department of State to issue IARP documents to US citizens for use in other CITEL countries. The FCC has asked the State Department to apply for participation in the CEPT Agreement as a non-CEPT country and expects the agreement to be concluded this year.

E-mail comments should mention "WT Docket No. 96-188" on the subject line and should be addressed to mdepont@fcc.gov. Include your full name and Postal Service mailing address in the message text. Mail written comments to: Office of the Secretary, Federal Communications Commission, Washington DC 20554—de FCC.

From *CARS, The Clearwater Connection*, October, 1996.

There's a Moral Here...

"Well, hello, Doug, good to see you. We've been trying to reach you for several days now!"

"That's interesting, Mike. I don't understand why. I have a telephone, call waiting, call forwarding, caller ID, an answering machine, a pager, facsimile machine, E-mail, all the amateur radio bands from 160 to 2 meters, packet radio, slow scan TV, and, of course, my portable cellular phone!"

"Sorry, Doug, but I simply rang your front doorbell. It must not be working!"

TNX KB8QLT, from March 1997's *Tuned Circuit*, monthly bulletin of the L'Anse Creuse ARC.

Build an Audio Multiplexer for Your Frequency Counter

Count CTCSS tones without expensive commercial equipment.

Roland Burgan KB8XI
RR1, Box 43
Hancock MI 49930
rburgan@up.net

Tired of struggling with low-end audio frequency counter readings, but not ready to shell out money for an expensive audio prescaler? Here's a much cheaper alternative.

The problem

Obtaining an accurate reading of repeater CTCSS (Continuous Tone Coded Squelch System) or tone-burst audio tones can be very difficult. If the counter's gate time is set to read out to 0.1 Hz, then usually the acquisition time required is too long. If the gate time is shortened as much as possible, the accuracy

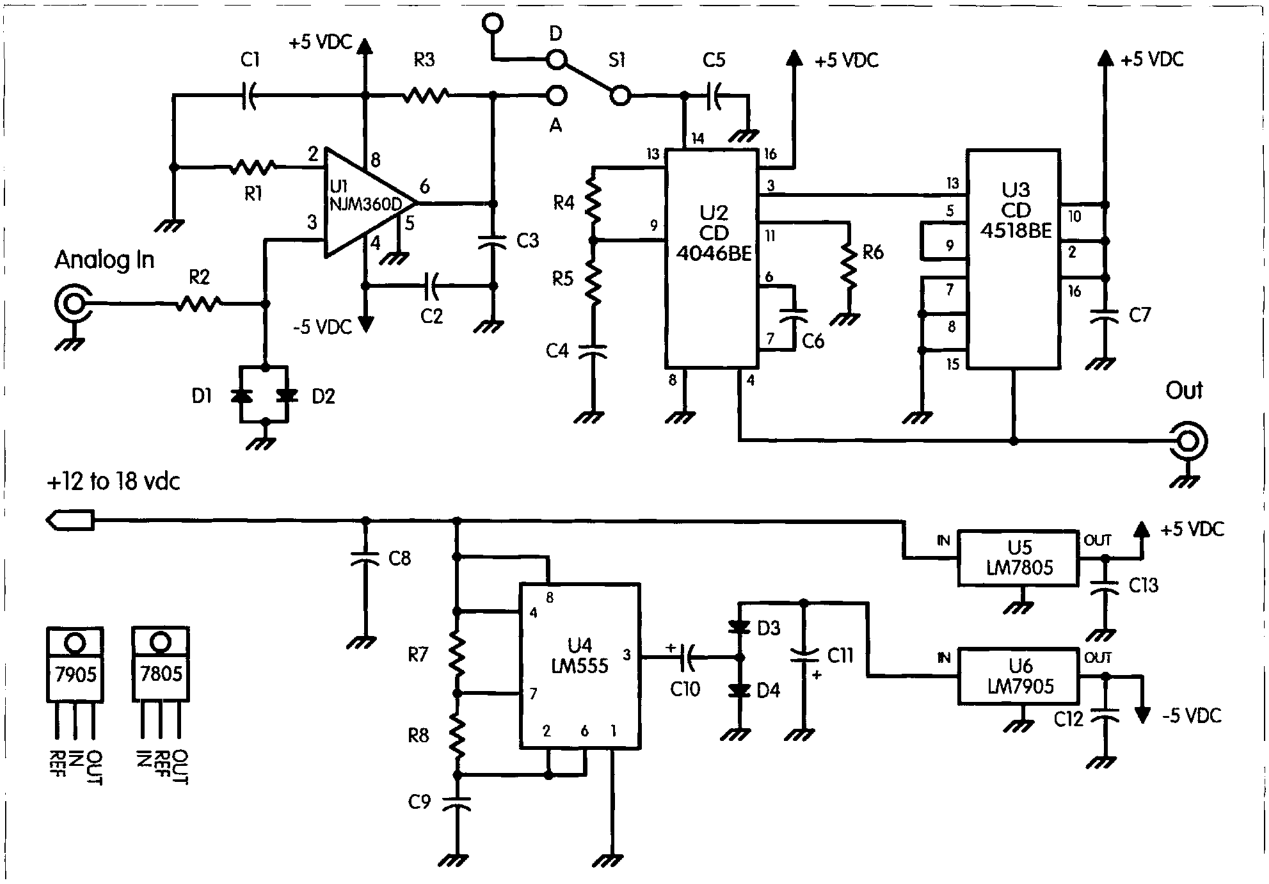

Fig. 1. Schematic for the Audio Multiplexer.

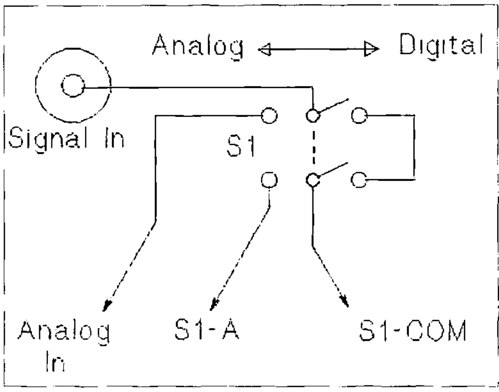

Fig. 2. For a single input, change S1 from an SPDT to a DPDT.

often proves inadequate. Until now, you had to buy either a more expensive counter or an expensive preprocessing unit to achieve the desired readout. But there *is* a way around the problem.

The solution

If we were to multiply the low frequency audio by 100, we could then get the desired digit accuracy in a fast time gate. We would only need to place the decimal point properly. Since shortening the gate time reduces the accuracy by one decade counter each step (a factor of ten), shifting the signal up times 100 restores the lost digit accuracy at the fast gate. It also adds another digit of accuracy, giving 0.1 Hz readings in the fast gate mode. The Audio Multiplexer will upconvert incoming audio frequencies through a range of 20 Hz to 8,000 Hz (8 kHz), and provide a TTL (transistor-transistor logic) output level. The unit may be powered from any single DC supply from 12 to 18 VDC.

The circuit

The circuit diagram (**Fig. 1**) shows the input analog signal fed to a voltage limiter (R2, D1, D2) to allow inputs to 50 VAC. U1, an NJM360D hi-speed comparator, amplifies and converts an incoming signal as low as 10 µV to a TTL signal. The TTL signal then goes to U2, a CD4046BE PLL (phase-locked loop). The output of U2, pin 4, is fed back to the U2 error input, pin 3, through the multiply-by-100 dual decade up-counter, U3, a CD4518BE, forcing the U2 VCO (voltage-controlled oscillator) to produce an output 100 times the original PLL input frequency (pin 14). A -5 VDC power requirement for U1 is met by U4, a 555, operating as an oscillator, whose output is rectified to produce the negative voltage. U6, a negative voltage regulator, provides -5 VDC. U5 provides a regulated +5 VDC to the rest of the circuit. Switch S1 provides for selection of analog (sine) input, or for TTL/CMOS square wave signals.

Construction

All parts are standard values, and are available from a variety of parts sources. C5 can be two .01 µF in parallel. Although the Audio Multiplexer may be wired point-to-point, the use of a printed circuit board is recommended (see Parts List). A metal box is recommended if the unit is to be used near transmitters. The choice of input/output connectors is left to the builder. Although the main schematic (**Fig. 1**) shows a split input, a single input may be used by changing S1 from an SPDT Switch to a DPDT (see **Fig. 2**). If +5 VDC and -5 VDC is already available, make appropriate connections at the connection points marked +5 VDC, and, -5 VDC. U4, U5, U6, and associated power supply components can then be eliminated.

Use

With no circuit adjustments to make, operation is simple. Just connect power, an audio source (below 8 kHz) to the input, and a frequency counter to the output. Use S1 to select sine/square input waveform. Remember to mentally adjust the decimal point two places to the left on the counter readout. Shielded cable is recommended for inputs, to minimize external noise. 73

"Remember to mentally adjust the decimal point two places..."

Build the Bioelectrifier

Can you heal yourself and take a poke at the medical establishment at the same time?

Thomas M. Miller WA8YKN
314 South 9th Street
Richmond IN 47374

Back by popular demand, this article is reprinted—with a new addendum—from May 1996.

One of the first things a new amateur learns is that electricity and biology are not very compatible. A brush with the AC line can be a painful experience, and accidental contact with the high-voltage supply of a large transmitting tube can be fatal. Because of this early training, occasionally reinforced by an unpleasant accidental jolt, it might surprise some hams that tiny electrical currents can be beneficial to the human body.

For some time, doctors have known that passing a small current through a broken bone will cause it to heal faster. Damaged tendons and nerves also seem to respond to this treatment. Exactly why this works is not known, although a doctor once explained to me that it seemed to focus the body's attention on the area.

Recently, doctors at the Albert Einstein College of Medicine reported discovering that passing a current of only 50 microamps through the blood can prevent certain viruses, notably the HIV virus, from replicating. The current became even more effective when the polarity was reversed several times a second. The implications are enormous.

Unfortunately, there has been very little interest in this phenomenon by the medical community. Those of us who read Wayne Green's editorials have become aware of a simple device which introduces a small electrical current through the legs by placing electrodes on the ankles. Since the arteries in the legs are large, and the blood has less electrical resistance than the surrounding tissue, this technique results in most of the current flowing through the blood. This is an ideal approach for amateur experimentation, since it is totally external, and the required voltage and current levels are so tiny as to pose no danger. I decided to design such a device, using a simple printed circuit board, and easily obtained parts, so that it could be duplicated by other amateurs.

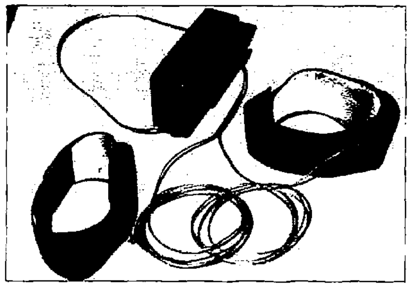

Photo A. The Bioelectrifier with belt clip and ankle electrodes.

At this point, let me state that I make no medical claims for this device. To paraphrase a famous Chief Medical Officer, I'm an engineer, not a doctor. Since very few doctors are electronics experts, there are many who would love to research the possibilities of this approach to eliminating viruses in the blood, but are unable to build the needed experimental device. They need your help.

So I present this circuit for those wishing to help doctors experiment in an unknown field, and also as an interesting study in design and construction.

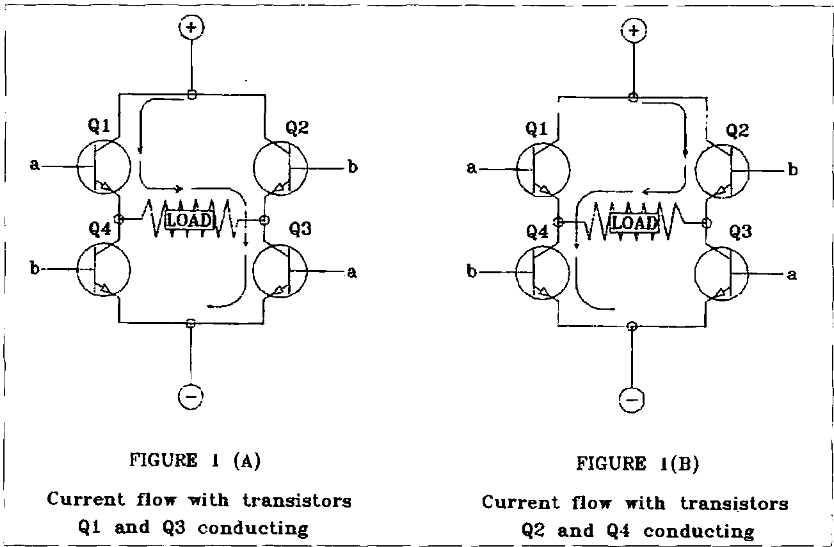

Fig. 1. Four transistors are used to reverse the current flow by being energized in pairs.

Designing a Bioelectrifier

Before attempting to design any device, it's a good idea to make a list of goals. In this case, it's a simple list:

(1) The device should produce a current flow of 50 microamps from one ankle to the other. Experimentation has shown that this requires 30 to 35 volts.

(2) It must be capable of reversing the current flow several times per second. This rate should be adjustable.

(3) It must be all solid-state—no DPDT relays clacking away, eating up the batteries.

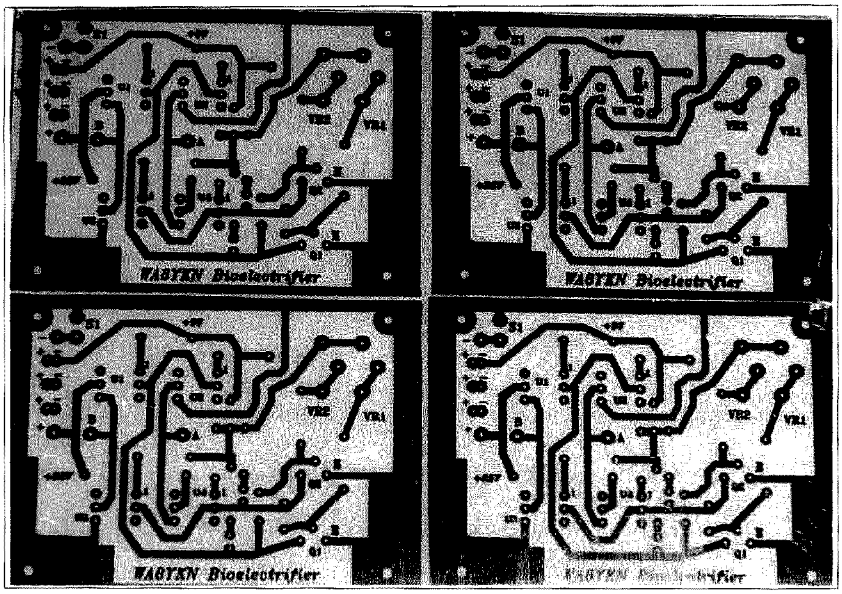

Photo B. Four circuit boards are etched on a single piece of copperclad and are cut apart after drilling.

(4) It must be small, light, and easy to carry. The ideal form would look like a pocket pager.

(5) It must have a low current drain for long life from small batteries.

(6) It must be as simple and inexpensive as possible, so that it may be easily reproduced.

This last goal is one of the most important in designing any device or circuit. It is, in fact, Occam's Razor, a corollary which states that when there are many ways to solve a problem, the best solution is the simplest one.

At first glance, it would be tempting to use logic chips, or perhaps a 555 timer and a flip-flop to get a variable timebase with an equal on-off ratio. However, this direction leads to a regulated power supply, high current drain, and a complex circuit. Also, logic chips will not switch 35 volts without an additional driver stage. Remember rule number six... the simplest way!

Maybe we'd be better off starting from the other end. Reversing polarity requires the solid-state equivalent of the DPDT relay. As it turns out, there is just such a circuit commonly used to drive and reverse DC motors. It uses four transistors in an "H" configuration, the load being in the center (see Fig. 1). When transistors 1 and 3 conduct, the current flows in one direction, while energizing transistors 2 and 4 reverses the flow. Most small switching transistors will stand up to our requirement of 35 volts at 50 microamps, but here we run into a new problem. For each direction, two transistors are in series, with the load in the middle. This creates a difficult bias arrangement to drive both transistor bases equally. Fortunately, there is a neat solution—the optocoupler. This invaluable device contains an LED and a phototransistor in one package. Energizing the LED produces light, which causes the phototransistor to conduct. No base voltage is required, therefore there are no bias requirements. Optocouplers are usually used to drive another device, but our requirements are so small that we can use them as output transistors.

The cheapest optoisolators cost less than a dollar and will withstand over 30 volts with current ratings in the hundreds of milliamps. For a few cents more, optocouplers are available that will withstand 80 volts or more.

With four optocouplers in the output of our device, all that remains is to alternately drive them in pairs. The simplest circuit to accomplish this is the multivibrator—nothing more than two general-purpose transistors, two resistors, and two capacitors. Voltage is not at all critical, and since we will be connecting batteries in series to get 35 volts, we can tap off at the 9 volt point to power the circuit. While we're at it, adding two more resistors and two tiny LEDs will give a visible indication of circuit operation and warn us when the battery goes dead.

Varying the frequency of a multivibrator requires that two resistors be varied together...no big deal. Two-gang potentiometers are ideal for this. In fact, our design goals do not specify that an equal duty cycle is required, or even desired. Two trim pots will give independent adjustment of the two states if this is needed. A fixed resistor in series with each pot will establish a maximum frequency limit, preventing the circuit from dropping out of oscillation when the pot is adjusted all the way.

We now have the basis of a simple,

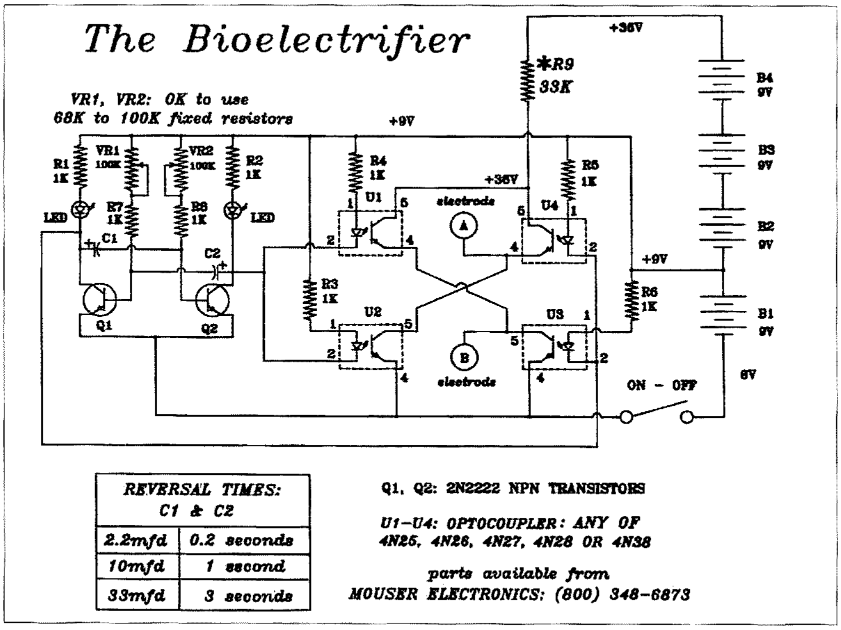

Fig. 2. Schematic diagram of the Bioelectrifier.

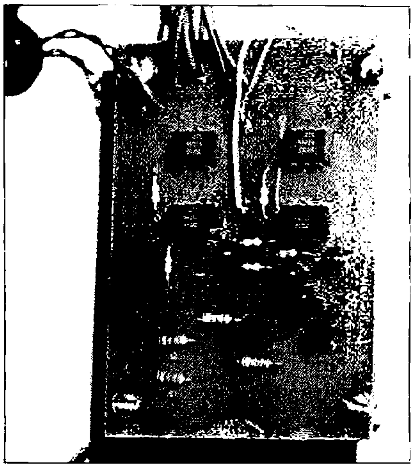

Photo C. The Bioelectrifier – component side of the board.

practical design: four optocouplers, two transistors, one dual pot, two capacitors, two LEDs, and eight resistors, all of the same value! The schematic diagram is shown in **Fig. 2.** Of course, we will have to add a box, switch, and batteries, and some sort of electrodes. We also need a name. Since we are experimenting in bioelectrics, let's call it the Bioelectrifier!

The printed circuit board

When designing a printed circuit board for this type of project, a compromise must be made between size and ease of construction. The board should be single-sided with as few jumpers as possible, and there should be enough room for 1/4 watt resistors, in case the smaller 1/8 watt are not available. The final design is shown in **Fig. 3.**

In my work, I design and build a lot of prototype circuits, and I've settled on an easy technique for circuit board fabrication. I use a Computer Aided Design (CAD) program to create the actual pattern, and then use the computer to generate a mirror image. If the board is small, as in this case, I will then copy this mirrored pattern to get the maximum number of circuits from a standard positive pre-sensitized copperclad board. This mirrored array is shown in **Fig. 4.** After printing this pattern, I copy it with a standard copy machine and inspect the copy for places where the toner is less than pure black. These areas, if any, are touched up with a felt-tip marker. When I've got a pattern that will give a good, pure black copy, I run two or three

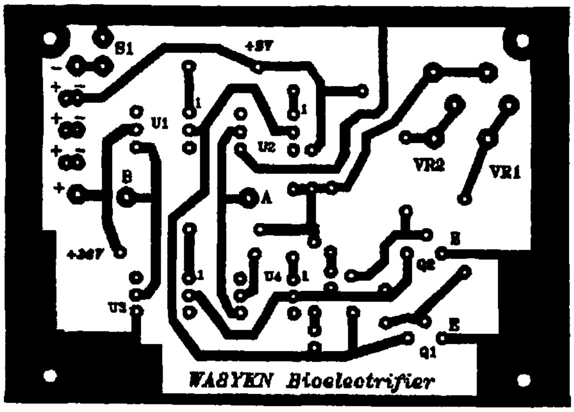

Fig. 3. The circuit board pattern, shown actual size.

copies to warm up the drum, then make a final copy on clear Mylar, sold in office supply stores for making overhead projector displays. It may be necessary to set the copy machine one step darker than normal, since machines tend to vary in how well they work with Mylar. This copy can be used as a positive for printing the circuit board.

Using a standard (4.5" by 6.5") presensitized board, place the Mylar sheet with the circuit board pattern *toner-side down* on top of the board. (The writing should be correct—not reversed!) Place a piece of glass over the Mylar to hold it in contact with the board, and expose it for three and a half to four minutes using an Ultra Violet sunlamp 12 inches above the board. Be sure to protect your eyes during the exposure!

After the board is exposed, dunk it in the developer until all the copper between the traces is shiny and clean; this usually takes around two minutes, but you really can't overdo it. Rinse the board with cold water, and it's ready to etch.

I etch my boards with ferric chloride solution in a tall, thin plastic tank that allows the board to stand up vertically. The use of an aquarium heater and air pump will cut the etching time in half. Do *not* get the etching solution on anything made of metal—it will corrode badly. It also stains everything, so wear rubber gloves and be careful!

After etching, clean the etch resist from the board, polish with steel wool, and drill the holes. The individual patterns can be cut from the board using a bandsaw, jigsaw, or even by hand with a hacksaw if that's all you have. You now have not one, but four circuit boards ready for construction.

Building the Bioelectrifier

Fig. 5 shows the parts layout for the Bioelectrifier. Be sure to install the optocouplers correctly. Also, the very small LEDs often do not have a flat spot to indicate the cathode, but instead have one lead shorter than the other. Check before cutting the leads! The *long* lead connects to the dropping resistor.

There are two ways that this circuit can be built. For experimentation, the device can be mounted in a larger box, potentiometers used to vary the frequency and current, and perhaps even a microammeter to monitor the current. However, I've discovered that it's not always wise to give a device with many controls to a non-technical person, especially if changing any of the adjustments would nullify the experiment. Also, we want a pocket-sized device, or one that can be clipped to the belt. Once the operating parameters are established, the resistance of the potentiometers can be measured and the pots replaced with fixed resistors (I used 68k). This makes a much smaller package possible, with only a single on/off switch and two tiny LEDs on the outside. I built one in a 2 7/16" by 5-1/16" plastic box (Radio Shack 270-233) and mounted the switch and LEDs in the end. Four 9 volt batteries would not fit in this box, but one 9 volt and two 12 volt "N" batteries will fit with no problem, and produce 33 volts. Radio Shack sells 12 volt alkaline "N" batteries in a package of two, (23-154) and "N" battery holders (270-405).

I made a belt clip from a strip of steel banding material and glued it to the back. I also glued a two-pole terminal strip to the end of the box to connect the electrode leads, although a plug and jack would be fine. I used what I had on hand.

Electrodes for the prototype were simply strips of aluminum foil, folded to form two strips several layers thick, 2 inches wide and 12 inches long. Wrapped around each ankle, the foil was held in place by rolling the socks up over it. Later, a better electrode was made by gluing aluminum foil to strips of cloth-backed vinyl

upholstery material, with hook-and-loop fastener material glued to the ends.

In either case, connect two 36-inch lengths of hookup wire to the Bioelectrifier's output terminals, and solder a paper clip to the other end of each wire. Slip one paper clip over each electrode, clip the Bioelectrifier to the patient's belt, and your doctor is ready to go.

OK, it's done. Now what?

Even if your doctor doesn't know anyone with the HIV virus, there are many experiments he can try with the Bioelectrifier. If it works on the HIV virus, what about others, such as those responsible for herpes, Epstein-Barr, colds, and flu? Will a few minutes a day actually *prevent* colds and flu? What effect will different frequencies have? The long-term benefits can only be determined by experimenting and recording the data.

It is interesting to note that all animal life on earth has evolved in the magnetic field of the planet. Blood, being mostly water and containing salts and iron, must generate a tiny voltage as it moves through this field. Is this voltage necessary for good health, and can it be disrupted by exposure to much more intense 60 Hz electromagnetic fields?

I've often wondered, as we think about manned missions to other planets, if we will one day discover that we cannot live for a great length of time without the Earth's magnetic field. So far, only a few people have ever left the planet, and only for a short time. These astronauts, however, have found that after a few days in space, the immune system starts to shut down! No one has yet found a good explanation for this. Perhaps a small application of bioelectrics is in order!

One interesting result reported by Wayne Green was that when his friend Beck used a similar device for two hours a day instead of the usual 20 minutes, just to see if there might be any harmful effects, he started losing weight! The weight loss continued until he reached his normal weight, then stopped. Since, as Wayne has repeatedly noted, many hams appear to be "eleven months pregnant," this could be the biggest thing since FM! Perhaps this device will open new fields of communication. Just adjust the frequency to match the 7 Hz resonant frequency of the Earth and tune your brainwaves to Dr. Jung's Universal Consciousness!

All kidding aside, there have been enough results from experiments to date to warrant serious study, and, as usual, mainstream science will continue to ignore it, while sucking up government funds for expensive and ineffective research. But breaking new ground is the amateur's forte. We have the technical skills and the manpower. Keep in mind that *every* new field is pioneered by amateurs—since the professionals do not yet exist!

One final caveat... *do not* build Bioelectrifiers and sell them as medical devices! This will surely bring unwanted attention from the wrong people. After all, these days even the U.S. Department of Health and Human Services has a S.W.A.T. team! So build it, work with a doctor to experiment, and make sure to keep careful records. Don't even give one away to someone who wants to try it but doesn't have the skills to build it, unless you have no qualms about opening yourself to almost unlimited liability. Remember, the FDA and several other government agencies have unlimited funds to persecute you, and they love nothing better than the slightest excuse to appear to be working. The last thing you need is to get the attention of the bureaucrats, who would probably protect the interests of the pharmaceutical cartels by outlawing bioelectricity, requiring us all to wear grounding straps on our behinds.

ANSWERS TO FREQUENTLY-ASKED QUESTIONS [NEW]

The response to the Bioelectrifier has been incredible. It's been a year since the original article saw print, and I can still count on a stack of letters every week. This stack becomes a flood whenever Wayne guests on the Art Bell show. Since there are common threads to many of these letters, I thought I should address some of the most frequently asked questions.

Bare circuit boards for the Bioelectrifier are available from FAR Circuits, 18N640 Field Court, Dundee IL 60118. And no, the phone has NOT been disconnected... the Chicago suburbs were assigned a new area code. Fred's number is (847) 836-9148.

Unlike the Rife devices, this circuit achieves its effect with direct current. However, the polarity must be constantly reversed because the body tends to quickly "charge up" and the current flow drops off. The frequency does not seem to make much difference, and I've used rates from 20 Hz down to 0.2 Hz successfully. One fellow sent me a very long table of resistor-capacitor values and wanted me to fill in the frequency for each combination! (Yes, he was a ham.) The time constant will vary slightly with the leakage of the transistors, but you can get very close by multiplying MEGOHMS by MICROFARADS to get time in SECONDS.

The original ankle cuffs lined with foil made a good "field expedient" electrode, but after a time, the foil becomes wrinkled, and the resulting hot-spots feel like tiny critters nibbling at your ankles. An alternative is to line the cuffs with 2-inch-wide heavy stainless-steel tape, available from any auto parts store, or by mail from J.C. Whitney. This material is heavy and polished, and doesn't wrinkle easily. It's also possible to take the advice of Dr. Hulda Clark and wrap a layer of saltwater-dampened paper towel between the metal surface and the skin. If the electrodes are working properly, you can't feel 100 microamps.

By far the best alternative is the disposable EKG electrode. These are "peel-and-stick" with a non-messy conductive jelly. These are so good that you can get two to three times the current flow and not feel a thing! They are available from your doctor or chiropractor, or you can order them through your pharmacist. EKG leads are

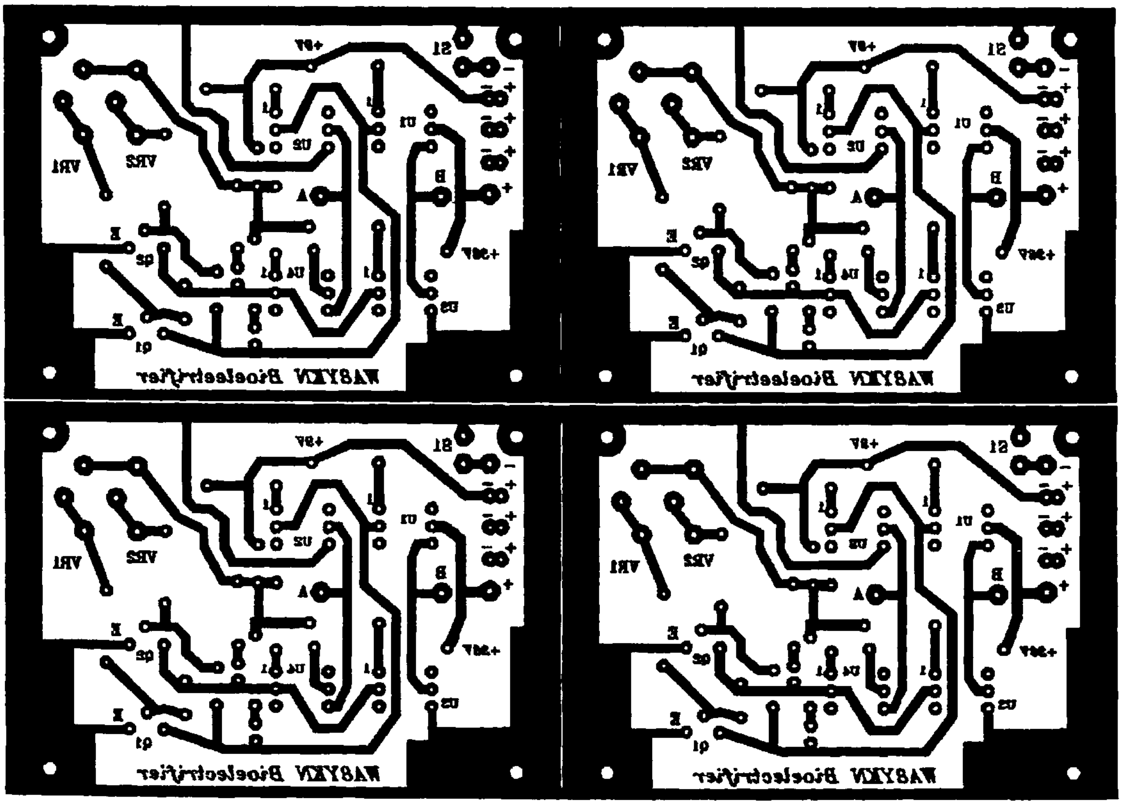

***Fig. 4.** Make your own "positive" by copying this mirrored pattern onto clear Mylar. Shown actual size.*

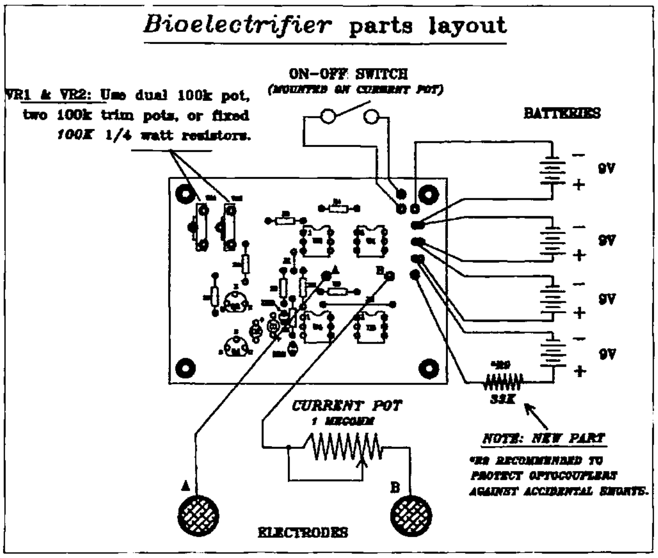

Fig. 5. Component side of the board, showing the component locations and connections.

made to snap onto the electrode, but small alligator clips work just fine.

If you write to me for information, please include a business-size SASE. My updates are now running three pages, so a post card won't do it.

While I can answer questions about the circuit, availability, and operation, remember that I'm an engineer, NOT a doctor. Please don't send me a letter detailing your health problems and asking for advice. That would put me in the position of practicing medicine without a license, and I can't do that! For information on what others have done and their results, get a copy of Wayne Green's AIDS booklet. Also, Dr. Bob Beck lectures all over the country, leaving a trail of informative audio tapes and written reports in his wake. By the way, Robert C. Beck, D.Sc. and Robert O. Becker, M.D. are NOT the same person!

An important point brought up by Dr. Beck is that when using any bioelectric device, it's necessary to stay away from toxic drugs, alcohol and even herbs. An effect called ELECTROPORATION can increase the effect of these chemicals and cause toxic effects from a normally harmless dose. Dr. Beck also stresses the importance of drinking lots of pure water before, during and after using any bioelectric device.

I hope that readers will share the results of their experiments with the Bioelectrifier. You can write to me, or send me E-Mail at [thomil@infocom.com]. My Web site [http://www.infocom.com/~thomil/] is a good place to watch for new information, which I will post as it arrives.

—Thomas M. Miller WA8YKN

Bioelectrifier Parts List

Etchant	ER-3

NOTE FROM W2NSD/1

I would make a lot more noise about this except for two things. Make that three. First, I'm not an MD, so the medical industry will probably have no interest in anything I have to offer. Second, efforts to try and bring down the cost of medical treatments could easily trigger an FDA attack and prison. Third, I need more people to call or write to say they used it with success. I've never had anyone write and say they had tried it and it didn't work, but I'd like more positive testimony.

Multi-Band Remotely-Tunable Inverted L Antenna

Here's a neat 160-40m wire antenna project using flexible parts-placement techniques.

Ronald Lumachi WB2CQM
73 Bay 26th Street
Brooklyn NY 11214-3905
E-mail: WB2CQM@Juno.Com

In the vast majority of antenna building projects, it's safe to assume that no two identically constructed arrays will exhibit the same electrical and performance parameters. Ground characteristics, proximity of trees, antenna length, contiguous buildings, height above ground, coaxial cable loss, velocity factors, etc., affect the ability of the system to radiate energy with a performance level equal to the criteria listed in the reference source.

When I set out to build, install, and test a base-loaded, remotely-tunable, multi-band inverted "L" for my home QTH, and then duplicate the project for my country location, little did I realize that the two locations had absolutely nothing in common with each other except that space was restricted for antenna erection. Ah! Ignorance is bliss!

I expected to breeze through the installation. For example, in order to raise the vertical portion of the antenna, I'd use the tower in the city and a convenient tree at the country location. The tower would be easy to climb to attach the supports. In the country installation, a slingshot, fishing pole, reel, monofilament line, sinker, pulley, and some nylon rope would make short work of this obstacle.

So, in my naiveté, I started on the city prototype. Duplicate capacitors, coil, motors, and hardware were assembled to address the requirements of both base-loading networks. After constructing the first matching network; wiring the entire assembly into the ground system (including the piping of my backyard well and the tower itself); and juggling components, the unit did a more than respectable job on 80/40 meters. Tweaking performance while surfing the frequency was as simple as toggling power to the remote motors and tuning for low SWR.

Confident in my skills, off I went to the country, armed with a clone of my successful prototype. I made absolutely certain that all the components were carefully spaced, firmly installed, and well bonded. Solder connections were double-checked for integrity and the circuitry was verified.

Suffice it to say that no manner of effort could get the array to work. Rocks, instead of concrete, and trees, instead of buildings (and who knows what else), all conspired to make for a monumental non-event. When every possible variation and combination of profanity had been expended and a cooler head prevailed, it became evident that obstacles had to be overcome by altering component positions (coil-capacitor relationships) to compensate for what I now knew to be a vastly different set of antenna-matching parameters. Exasperated, I took the unit apart.

That disheartening disassembly experience, however, resulted in the development of the construction techniques in this article. In a nutshell, it's a system of breadboarding using jumper cables, rather than hard wiring. It's easy to change component configurations within a circuit, on a temporary basis, of course, to maximize antenna performance for a particular locale.

Then, and only then, can all the parts be hard-wired into place, for a solid, low-loss, high-performing matching network.

What's first?

To utilize this strategy successfully, it's vital that you overcome the mindset that the location and hookup of the coil and capacitor components in the matching network are cast in stone! Simply because they were used successfully in one set of circumstances does not guarantee automatic success in another (seemingly similar) situation. Keep in mind that although the number and value of components may be the same, the way they're wired into the system and how they respond to the peculiarities of a particular environment make a world of difference.

Fig. 1 shows that there are plenty of matching options at your disposal to achieve that elusive 1:1 SWR. With that firmly in mind, a quick hookup technique gives you great flexibility, and minimal timewasting, moving components in and out of a circuit to test the various configurations. The goal is maximum signal radiation coinciding with the lowest standing wave ratio with the least expenditure of effort—the most gain with the least pain!

The answer is not to remove, rebuild and rewire the unit after each unsuccessful attempt to power up the antenna. That strategy becomes a tedious chore, increases your level of frustration, and is no longer even *close* to a remotely

rewarding situation after even only one or two failures. To make life easy, simply bypass the continual disconnecting and moving of hard-wired components by electrically isolating each of the discrete parts used in the circuit (coil, capacitors, tie points, etc.) and prepare jumper leads to complete temporary configurations.

If a particular arrangement does not work, remove the jumpers, refer to a second schematic, and reconnect for another try. If memory serves, programming the old IBM mainframes (circa 1960) was accomplished in the same manner, using a rat's nest of jumpers and clips. There's really nothing new under the sun!

Gathering the basic parts

It's a good idea to locate a source of supply and to purchase all the parts before planning any further. Reasonably-spaced air-variable capacitors as well as coils are expensive, so check the surplus catalogs, or scout a local hamfest for these items. In my case, I found that my primary loading capacitor with about 1500 pF, borrowed from an old linear, worked well. I also used a moderately-spaced dual-gang variable (150/150 pF) for the second unit. This component can be paral-leled for increased capacitance (with jumpers, of course), or left as two independent units for wiring up **Fig. 1(i)**.

It's important that both air variables rotate a full 360 degrees, since they will be driven remotely by the gear motors. As a last resort, the capacitors may have to be purchased from retail outlets; however, home-brew coils constructed from readily available material and tailored to the project's specific needs can save a bundle.

If you decide on remote tuning, pick up one or two gear head 1-rpm reversible motors. To reduce project costs somewhat, the second motor (or both) can be a standard 1-rpm synchronous model. It works just as well, but I found that it wasn't as convenient for quick fine-tuning. Try to find units with identical driving voltage requirements. Suppliers are listed here, but they should be telephoned to verify current inventory.

Don't forget to scout the local hamfests for your needs. You'll need everything at hand to lay out the parts in the most compact manner. Keep in mind that all the components are mounted above ground potential.

Since the matching unit also needed to be protected from weathering, the container selected was nonconductive PVC. I made a quick visit to the housewares department of the local K-Mart™ and ended up with a plastic box originally designed for storing shirts and sweaters. You'll discover an almost endless array of sizes, but it's important that there is adequate depth so the cover can be fitted for weatherproofing without any obstruction.

With the exception of the coil, all the parts were mounted directly to the

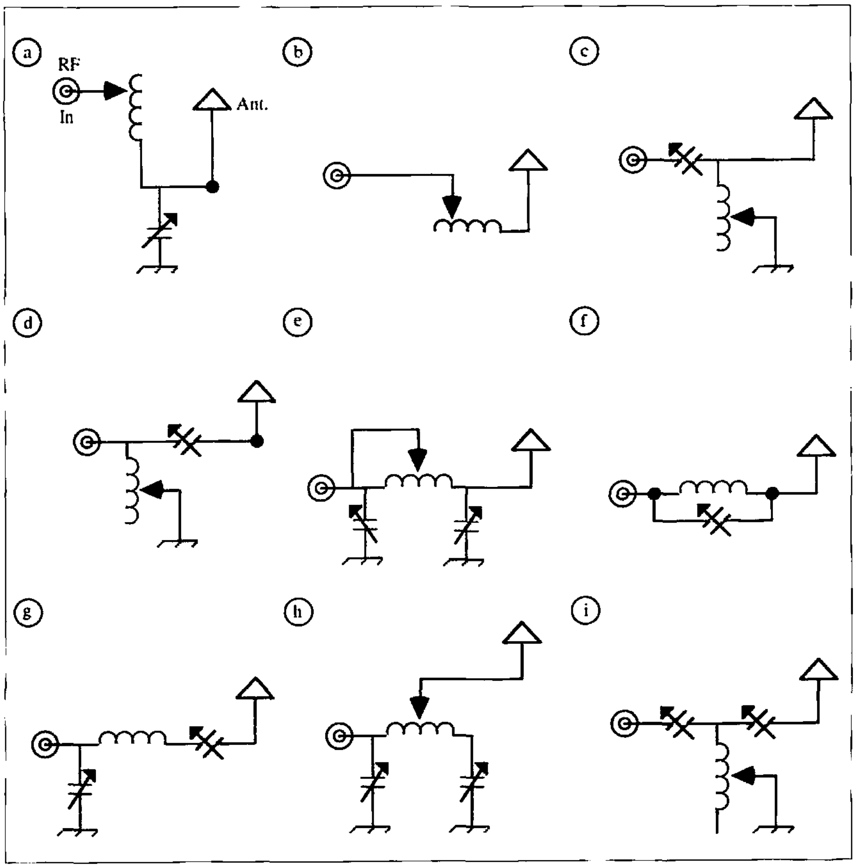

Fig. 1. Possible coil/capacitor combinations for antenna matching.

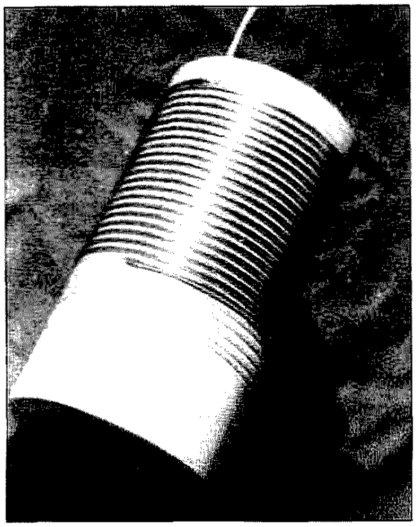

Photo A. The six-inch length of PVC piping, threaded at 6 tpi, with the coil temporarily wound on the form.

container using junk box hardware. As a precaution, the coil was further isolated from the other components by using short porcelain standoffs. All that remained was to construct (or purchase) a hefty wide-diameter coil that would provide about 22–28 mH.

Home-brewing the coil

If you want to experience sticker shock, take a look at the prices for air-wound coils with 3 to 3-1/2" specs. I decided to wind my own using a section of 3" PVC tubing (3-1/2" OD) 6" long and 22-24 turns of #10 AWG solid copper wire at 6 tpi. Look for discarded PVC cutoffs at a new home construction site (with permission, of course) or purchase a 3-foot length at a home improvement center. It's cheap enough and there will be many other occasions when there will be a need to wind coils.

You'll need approximately 25 feet of solid bare wire (available off the shelf from an electrical supply house or other source). If you experience any difficulty in locating this type of material, electrician's household AC wire with the protective covering is OK (#12 AWG wire can be substituted with only a slight reduction in performance). Suppliers will cut it to length off a roll, but make certain that it is not kinked in the process.

"Don't be afraid to tweak your signal with the rocker switch."

Removing the covering is tedious, so it's vital to have a wire stripper with a fixed calibration for 10-gauge wire. Clamp one end of the wire in a vise or loop it around a fencepost and stretch it taut. Remove repeated 6-inch lengths of plastic insulation material by walking the covering down the length of wire. Try not to nick the wire, because that creates an obstacle to the smooth removal of the covering as you move each length down the wire. It may help if you keep the bare wire lubricated with concentrated dishwashing liquid.

Although not essential for winding accurately-spaced coils, it helps if you can have the PVC tubing threaded or at least scored at 6 tpi. If you're not fortunate enough to have (or have a friend with) a lathe, visit your local machine shop. It makes for foolproof winding, but again, threading or scoring is not essential for this project.

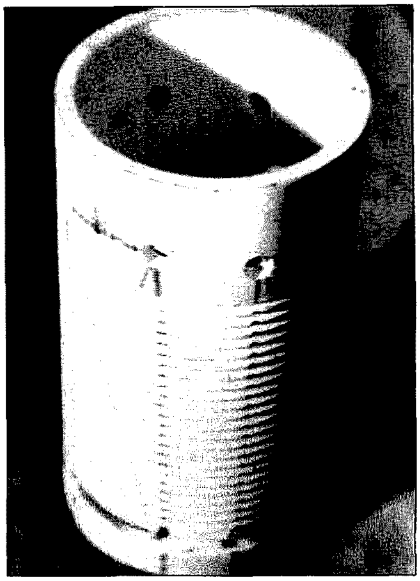

Photo B. Remove the coil and measure the 4 sections. Cut away the four 2" x 4" sections (marked with the X).

Assuming you're unable to have the threading done, close-wind the full length of wire on the form, keeping the wire taut (**Photo A**). Do exactly the same thing for the lathe-prepared coil form, except follow the threading. In either case, remove the coil of wire from the form after winding. You'll find that your newly-wound coil resembles a Slinky™, and it will be OK to reminisce about your childhood (but only briefly). Force yourself not to try it out on the staircase, since it doesn't have quite the same characteristics as the original.

Using a tape rule, measure around the perimeter of the PVC pipe and divide the circumference equally into fourths (approximately 2-3/4" intervals) (**Fig. 2**). Using a try square, draw a pencil line down the length of the PVC, perpendicular to the face of the pipe at each of the four points. Draw two parallel lines one inch on each side of the reference line, stopping one inch from each end of the PVC. Form four rectangles (each measuring 2" x 4") and drill a 3/8" starter hole at each of the eight *inside* corners (**Photo B**), and use a saber saw to make the cutouts as shown.

Before rewinding the wire onto what has now become an air-wound form,

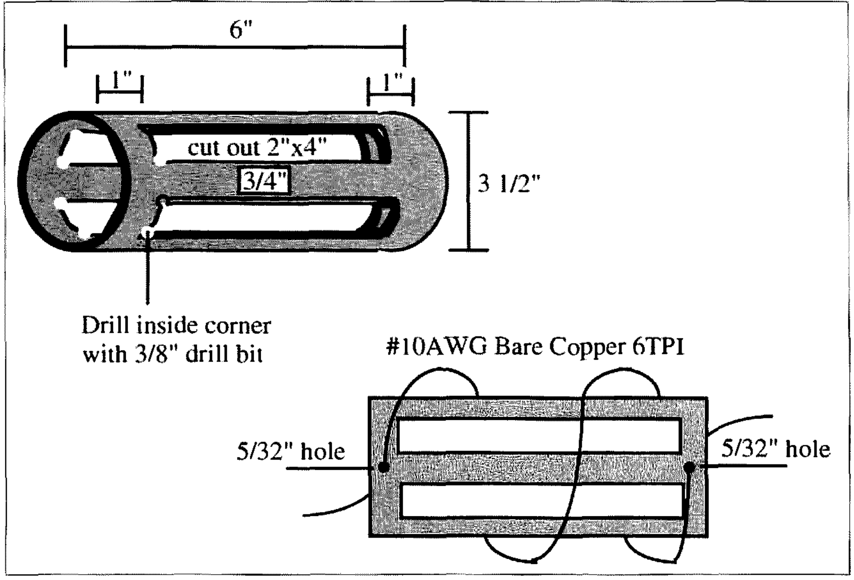

Fig 2. Coil form details.

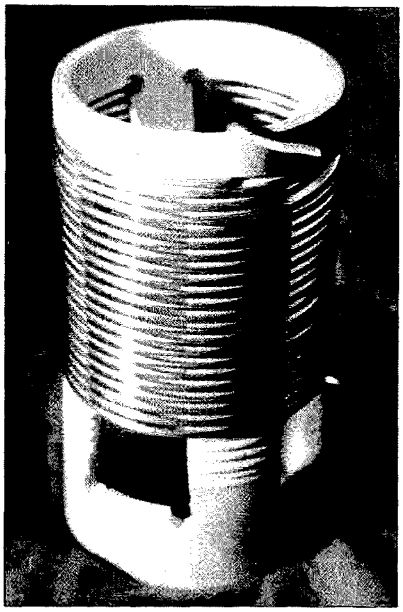

Photo C. Rewind the coil on the form. Note that the ends of the coil are protruding from the top and the side and will be used for hookup points.

drill two 5/32" holes in alignment along one of the support ramps one inch from each end of the PVC. If your measuring and cutting is reasonably accurate, the remaining four sections of wire-supporting PVC should each measure approximately 3/4" x 4" long.

Start the rewinding process by placing an end of the coil into one of the small holes (**Photo C**). Rewind your Slinky, keeping a moderate tension on the form. It might help if you can borrow another pair of hands, since 10-gauge wire often has a mind of its own. At the 24th turn, thread the end of the coil into the remaining hole, give it a twist with a pair of pliers, and you're ready to move on.

Leave a sufficiently long pigtail on each coil end for hookup points. If the form is not threaded, adjust the spacing evenly along its length. If you're concerned about minor changes in the value of inductance, run a couple of beads of silicone caulk or hot glue along the coil's length to ensure rigidity.

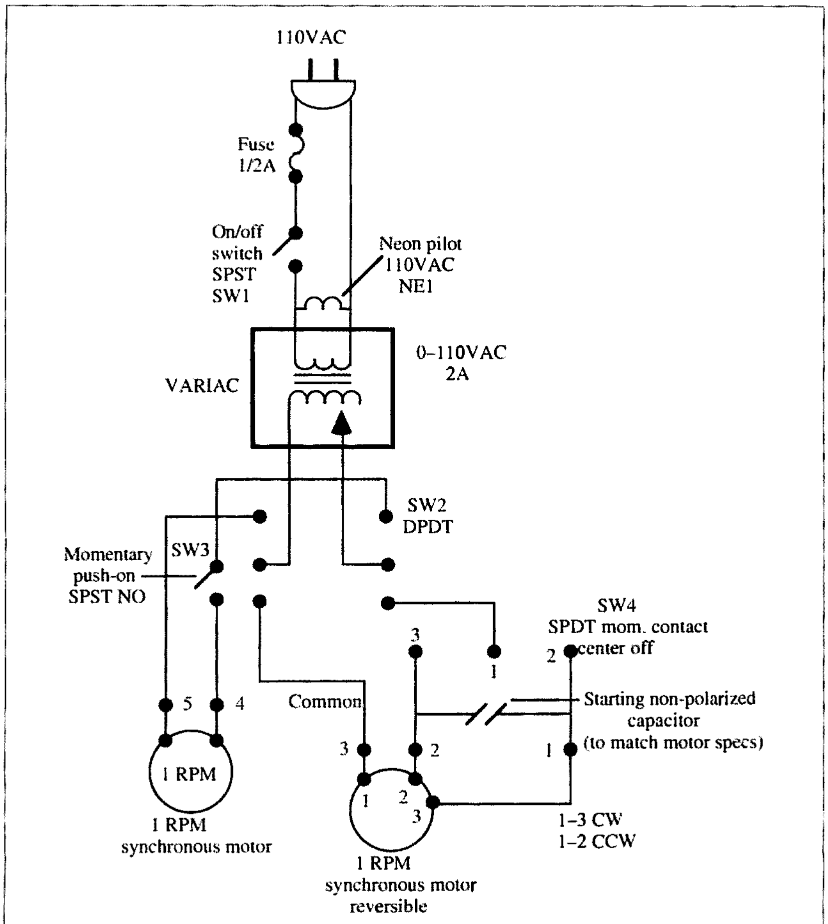

Fig. 3. Straightforward power supply wiring schematic to power the two remote synchronous motors.

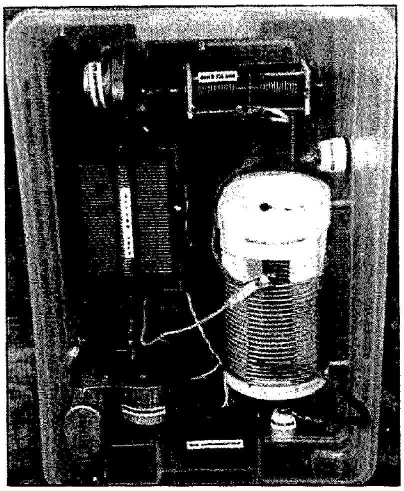

Photo D. Located below the coil is the antenna input feedthrough insulator. At the upper right is the antenna output feedthrough.

The home stretch!

Mount each of the components and drive motors directly onto the enclosure. Don't forget the standoff insulators for the coil. Use my model (**Photo D**) as a placement guide or feel free to configure your own. Mount feedthrough insulators on the side for the antenna output and one on the bottom for input. A heavy brass nut, bolt, washer, and solder lug provide for a solid ground attachment point.

I used a five-position barrier strip to wire the remote tuning motors, via a five-strand rotator cable, to the 110 VAC variac supply. The Powerstat driven voltage supply was used only as a convenience to drive gear motors of any voltage. Often, it's pot luck when you're looking for appropriately rated miniature AC motors, and only odd voltages are available. Incidentally, it's usually cheaper to buy 20 VAC units instead of 110 VAC models, for obvious reasons. Remember, if you want to stay flexible use a variac with this aspect of construction. However, discrete isolation transformers, with output ratings to accommodate odd motor voltages, can be substituted and will work just as well.

Keep in mind that the use of a variable-voltage power supply option will not affect the shaft output speed if you deviate from the synchronous motor's voltage rating. They're specifically designed that way in order to maintain rated output even with 10-20% powerline fluctuations. Check **Fig. 3** for the straightforward wiring of this power supply component.

I used a scrap piece of 4-inch PVC and two matching caps to form the enclosure (**Photo E**), but any type of case will work just fine. The 2-amp variac was mounted inside one of the PVC caps along with an on/off switch and a power indicator light. Five binding posts were placed near the bottom of the unit. In close proximity, mount a DPDT and SPST (normally open) momentary-contact switch. These toggle voltage to the two motors and activate the 1-rpm synchronous motor, respectively. The momentary-contact center-off SPDT switch drives the reversible motor and will change its rotation

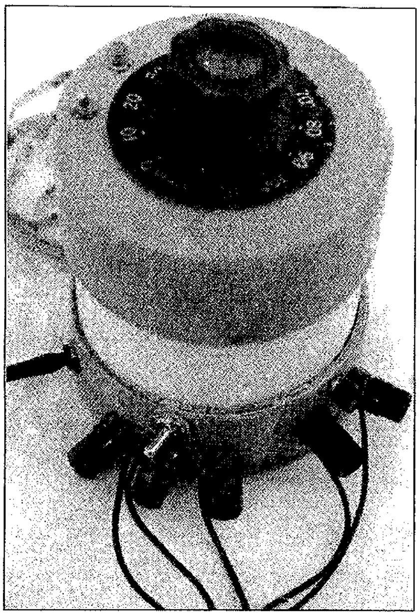

Photo E. Two PVC caps and a short length of four-inch plastic pipe provide an enclosure for the variac AC power supply.

depending on the switch position. This is a great (optional) feature since it allows you to rock the capacitor to tweak the output (**Photo F**). Use self-tapping screws to secure both the top and bottom cap to the length of piping.

Solder eight- to 10-inch tinned lengths of 58U copper braiding or flexible wire to the input and output of the coil and capacitors, and attach alligator clips at each of the ends. Prepare an additional supply of jumper cables with double-ended clips (**Photo G**). Mount the matching network enclosure near the base of the antenna. Wire the coax to the input and ground, and the output to the longest length of antenna you can muster.

Use a strain insulator between the antenna and the network's input to

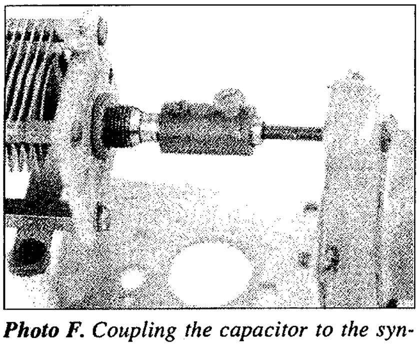

Photo F. Coupling the capacitor to the synchronous motor can pose a minor problem if the shafts have different diameters.

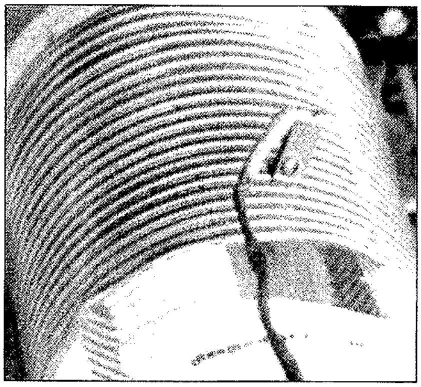

Photo G. The alligator-type jaw of a clip I found at a hamfest is opened by loosening the set screw and then pressed onto the coil.

eliminate the possibility of damage from the wind. Before flat-topping the array, it's always a good idea to get the vertical radiating portion up as high as possible for the best propagation characteristics. Although random lengths of wire will usually work okay, it is preferable to measure out multiples of 65' to ease loading.

Using the jumpers, wire up the first circuit following one of the schematics. I've found that the MFJ-249 SWR analyzer quickly indicates if you're on the right track and is infinitely more convenient than using your transmitter and SWR bridge. It's great to watch the SWR dip as the capacitor values interact in the matching network when altered remotely from the convenience of the shack.

If you're not happy with the results, move on to the second wiring option and hit your switches. Coil taps may have to be altered, but it won't be long before the exact combination of components and values will be radiating your signal into the air where it belongs. When the best combination has been determined, and maximum signal radiation has been achieved, replace the jumpers with hard wiring and install the weather-protective cover.

Once you're set up on any frequency, don't hesitate to make excursions over the entire band and tweak your signal by using the rocker switch to dip the SWR meter. If you're fortunate, you'll find that you can tune 40 meters with a minimum of capacitance and move to 75/80 meters on the same coil tap by adding more capacitance. Try it—you'll like it! 73

Ham Vacation

A six-week journey through Yugoslavia.

George Pataki WB2AQC
84-47 Kendrick Place
Jamaica NY 11432

In the summer of 1996, I visited many amateurs in Hungary and Yugoslavia. I was able to see many radio clubs and personal stations, where I noticed the large number of YLs and XYLs, as well as youngsters, participating in the hobby.

Family ties in eastern Europe may be stronger than those in the West. This can be attributed to tradition and education, and perhaps to the fact that there are fewer attractions available outside the family than there are in more affluent societies.

In Yugoslavia, a large part of ham activity is in radio clubs. To operate a radio station, just like in other countries, you have to pass an examination. There are two kinds of amateurs: those who are licensed to operate radio stations but don't have personal calls, and those who have callsigns. To get a personal license and a callsign you have to be at least 18 years old. Therefore, even well-trained youngsters are limited to working through radio clubs, using the club's call, under the supervision of a fully licensed amateur. Even adults in the first stage of their ham activity start by being an operator at a club.

***Photo A.** Joca YU1JS and his wife Svetlana YT1JJS in Ripanj.*

Every club has a name. The most favorite namesakes are Nikola Tesla and Mihailo Pupin, two famous native sons who made important contributions to electrical science. If these two names are already taken in a locale, then a new club will go for a geographical one. Many hams and radio clubs have huge towers and antennas, and there don't seem to be any restrictions or zoning laws whatsoever.

"The economic situation in the country has deteriorated because of the war... The sales tax, for example, is 26%..."

Every amateur has to be a member of a club and every club has a fully equipped radio station. Those who have personal callsigns and can afford to buy their own gear and set up a station at home often involve members of their immediate family in this hobby. I saw several husband/wife and parent/children teams. In most cases the husband, or father, was the more advanced in the family, but there were also instances where husband and wife had licenses and achievements at the same level.

The Radio Amateur Association of Yugoslavia, a member of the IARU, is very well organized. There are many kinds of activities, both in the numerous clubs and by individual hams. Years ago, the YU hams had the best equipment in eastern Europe because they had more freedom to travel. Thousands of Yugoslavs worked in western countries, especially in West Germany, and they could afford (and had the chance to buy) all sorts of modern appliances.

In recent years, however, the economic situation of the country has deteriorated because of the war in Bosnia and the blockade that followed. The sales tax, for example, is 26%. These days, there are very few dealerships selling radio equipment. Most of the gear, made in Japan, is brought in by occasional travelers and is very expensive.

In Yugoslavia, there are six categories of license, A being the highest and F, the lowest. The maximum allowed power is 1.5 kW; on the WARC band and on six meters, only 300 watts is permitted. The test for the A license requires code operation at 20 wpm, and the A hams have allband privileges. The no-code E licensees can use a maximum of 30 W on two meters and 70 cm.

I used Belgrade as headquarters on my trip. At the YU1IOP radio club there, among the many hams I was fortunate enough to meet were two couples: Lidia YT1LID and her husband Dragan YT1SDV; and Mira YT1MIR and her spouse Uros YU1EG.

***Photo B.** Toma YU1AB and his wife Sladica YU1SL in Valjevo.*

Photo C. Rade YT1FRR and his wife Cica YZ1DTS operate on the 2m band in Kragujevac.

While in Belgrade, I went to see Elmax, a repair shop specializing in amateur radio equipment. They have gear made by Kenwood, Yaesu, Icom—even some vintage Collins transceivers. They also build new equipment on special order: I saw a very nice 1 kW amplifier. The shop's owner is Max Maksimovic YU1MM; his wife is Rose YT1NZN. Their shop is a meeting place for amateurs with or without any business to conduct.

Belgrade is also the home of Buda YT1RBB, his wife Jela YT1EYL, and their daughter Jasmina YT1RYL. All three have VHF licenses and operate only on 2m with a homemade 25-watt amplifier. They live on the ground floor of a 16-story building, where the coax cable from their shack to the 12-element homemade yagi on the roof is 247 feet long.

In the village of Ripanj, where we went next, there is a couple living on a small farm: Joca YU1JS and his wife Svetlana YT1JJS (**Photo A**). Their daughter Dragana, who died in a car accident, was an operator at the YU1AIE club station in nearby Lapovo.

In Valjevo, about 62 miles southwest of Belgrade, we met Toma YU1AB, ex-YU1DZ, and his wife Sladica YU1SL (**Photo B**). It is hard to believe that Toma has only a multiband dipole, and a 17-element yagi for 2m, because he is on the DXCC Honor Roll No.1; *CQ* DX Honor Roll; WPX Honor Roll; and has the 5BDXCC, 5BWAZ, etc. The reason is that in Lajkovac, in his parents' house, Toma has a big station feeding 1 kW to a 4-element tribander on the top of his 56-foot-high tower.

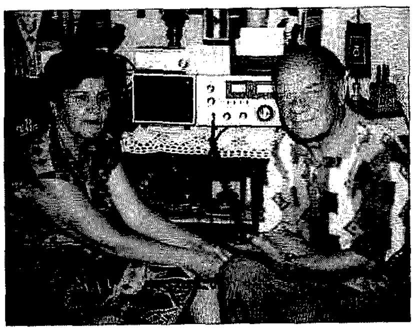

Photo D. Radmila YU1GR and her husband Ivan YU1HA, in Kragujevac.

Toma is the president of YU1GTU, contest call YT1L, the radio club in Lajkovac. They use 1 kW and have 338 countries confirmed. We also met Slavko 4N1RS, Dusan YT1DL, Voja YT1DOS and his son Milan. On top of the club's 60-foot tower there is a 3-element yagi for 10-15-20m, an 11-element yagi for 2m, and a couple of wire dipoles for 15 and 80.

One morning, Rade YT1FRR, his wife Cica YZ1DTS (**Photo C**), and Milan YZ1PWO picked me up at my hotel. We drove to Kragujevac, population 180,000, about 65 miles south of Belgrade. There we visited Ivan YU1HA, president of the local radio club YU1EFG. Ivan, a retired sergeant, was a partisan during World War II. His wife Radmila YU1GR was licensed in 1968. They have a good station, with a ground plane for 10-15-20 meters and a wire dipole for 40 and 80. Both work only on CW and have impressive records. Ivan is a contester, with 700,000 QSOs, 361 countries confirmed, and 1,384 awards; Radmila has 289 countries for her DXCC (**Photo D**).

I also met Mile YU1QQ and his son Nikola while they were operating from the YU1EFG club station (**Photo E**), as well as Ratko YU1NR and his XYL at their home in Kragujevac (**Photo F**).

Ivan and Radmila have a second house in Knic, about 13 miles from Kragujevac, with a homemade 70-foot tower, a 3-element cubical quad for 20m, and a 4-element quad for 10 and 15. A second tower, 33 feet high, has a 5-element yagi for 6m and a 21-element yagi for 2m. They also have a 2-element wire beam for 40m directed to the US, and a horizontally-polarized Delta loop for 10 to 80. They use 1.2 kW and have lots of homemade equipment. Now maybe you understand where those 700,000 QSOs have come from?

In Jagodina, I found Miodrag YZ1MCM, who works in the local electrical cable factory, his wife Ana YT1ECA, and their daughters Monica YT1ECM and Isidora

Photo E. Mile YU1QQ and his son Nikola operating at the YU1EFG club station in Kragujevac.

YT1FCI (Photo **G**). All have VHF/UHF licenses and operate on the 2m band, which in Yugoslavia extends from 144 to 146 MHz.

Rade 4N1RK drove Miodrag YZ1MCM, Zoran 4N1EV, and me to Cuprija, where we saw Mile YU1MI. A salesman of electrical and electronic equipment, Mile uses a computer for packet, has a 100-watt transceiver, and is building an amplifier. On his 50-foot homemade tower, he has a 3-element yagi for 10-15-20m; two 11-element yagis, one vertically-, the other one horizontally-polarized; and 3 dipoles for 80, 40 and 20m. Mile has an A (Extra) class license and a nice QSL. His daughter Dragana YZ1NZC has a VHF/UHF license for 2 meters and 70 cm.

In Krusevac, population 42,000, I found the YU1ADO radio club. Its secretary is Lila YZ1SL, who received her B license in 1995. She works at the post office. The club has 80 members. They use a TS-430S with an 800-watt Yaesu FL-2277B amplifier. The antennas are: a Delta loop for 80m; a dipole and an inverted V for 40m; and a ground plane for 20. The club has about 200 countries toward their DXCC.

I also saw Lila's home station, YZ1SL. Her family are refugees from

Photo F. Ratko YU1NR and his XYL (no personal call) in Kragujevac.

Photo G. Miodrag YZ1MCM and daughter Monica YT1ECM in Jagodina.

Bosnia, where she was X5SL. Her husband Saki works in a metallurgical factory—he used the X5SV call, with the controversial X5 prefix, in Serbia. Their son Andrej is in high school, and their daughter Aleksandra is in college studying economics; both have class C operating licenses without personal calls. They work on SSB and CW with a small transceiver and a dipole for 80m (**Photo H**). [Note: The X5 prefix used by the hams on the Serbian side of the divided Bosnia-Herzegovina is unofficial. It will be used until the status of this disputed land is clarified and an official prefix is assigned.]

I finally got to Kraljevo, where the first hams I visited were Rate YT1EKR and his wife Goca YT1RGA (**Photo I**). Both have been enthusiastic CB operators for many years. Now they have no-code E licenses without personal callsigns, and with 30 watts and a 7-element vertically-polarized yagi they also operate on 2m.

About 6-7 miles from Kraljevo is the small village of Vitanovac, where one of the greatest stations I have ever seen is located. It belongs to Hrane YT1AD, the

Photo H. Son Andrej (no personal call), mother Lila YZ1SL, and father Saki X5SV in Krusevac.

Photo I. Rate YT1EKR and his wife Goca YT1RGA of Kraljevo.

president of the Radio Amateur Association of Yugoslavia. Hrane is in the import-export business and lives part of the time in Moscow, Russia, where he is RV7AD. Because he was at a ham meeting in Kraljevo, his brother Milovan YT1IM showed the whole setup to me and Simo 4N1SM, who had also come along. The station has a couple of transceivers and linear amplifiers—nothing unusual in the house of a very rich man. Milovan, Simo and I tried to figure out the multitude of towers and antennas. On a 122-footer, there is a 7-element yagi for 10m; a 4-element yagi for 40m; and a 6-element yagi for 10m fixed in the direction of the US. On a 99-foot tower, there are two yagis for 2m, one horizontally-polarized, the other vertically-; and a 6-element yagi for 20m. On another 99-foot tower, there is a 6-element yagi for 15m; a 3-element yagi for 12-17-30m; and a 6-element fixed yagi directed toward the US. Near the house, on a mast, is a 6-element yagi for 6m. All cables are run underground, despite the long distance from the towers to the building. There are also a bunch of wire antennas we could not figure out.

I met many hams on my trip. I'm sure that among them there are many more who have licensed amateurs in their families. I did not always ask them about this. Those who supplied such information were proud and happy that their hobby and interests are shared by the people closest to them. And that's the way it should be.

73 Review

Timewave Technology's DSP-599ZX

Excellence in digital signal processing.

Jim Kocsis WA9PYH
2217 Hidden Oaks Ct.
South Bend IN 46628

Timewave Technology, Inc.'s new DSP-599ZX is an audio digital signal processor (DSP) made to improve communications in many different modes by reducing noise and interference. It uses an A-to-D converter to digitize the incoming audio signal, runs the digitized data through software algorithms to eliminate all but the desired signals, and then outputs the remaining digital data through a D-to-A converter and audio amplifier.

Why did I want a DSP?

I had read several product reviews on available units and tutorial articles on how they work. After reading about it, and seeing how powerful DSPs are in applications where I work, I decided I could make good use of one in my DXing, CW and future satellite activities.

The first thing I noticed about the 599ZX was the high quality of construction. It is very solid and heavy. Digital encoders are used for two of the three variable controls. This is nice because they won't get dirty and become intermittent like typical potentiometers. The third knob is the volume control—it is a common potentiometer. The display window is a 2-line by 16-character backlit yellow-green LCD. Additional individual LEDs are green, yellow and red. The unit is compact—approximately 8 x 9 x 2 inches, small enough that I set mine on top of my HF rig, so the controls are close when they need to be adjusted.

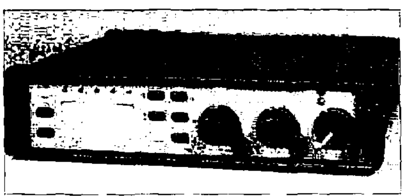

Photo A. Front view

All input and output connections are via phono jacks, so you won't need to buy any high-priced or hard-to-find connectors. You can also use the two DIN connectors that provide access to the same signals. The 599ZX has connectors for two radios. Via the front panel you select radio A or radio B and audio output A or B. Having two channels that are selectable from the front panel eliminates having to unplug and plug connectors when switching between radios. The power connector is supplied so you don't have to run out to get one. According to the manual, the unit requires 1 amp at 12 VDC for proper operation, but I measured .65 amps at normal volume levels. They probably specified 1 amp to make sure the voltage doesn't droop when the volume is set to high levels. I powered my 599ZX from my HF rig's power supply since it is rated at over 20 amps and one more amp of current won't even be noticed.

So how do you operate this little gem?

The manual is very well organized. It has a Quick Start section so you can begin using it immediately, and separate chapters on CW, voice, data and test modes. I highly recommend reading the *entire* manual first so you can determine all that this very powerful unit can do. Be aware, though, that there is a lot to this unit and you won't remember how all the functions work by reading the manual once. The manual I received had occasional quirks—extra words, awkward sentence structure, etc., but this didn't keep me from using any feature. The manual was three-hole-punch pages held together by prong paper fasteners. As I turned the pages, the manual literally fell apart in my hands. I bought a 50-cent three-ring binder with fold-down tabs and a clear front cover (it would have been nice if Timewave had supplied this). Pictures are plentiful, showing which button or control to adjust.

CW—where the unit really excels

The 599ZX has a spot feature that you use to match the tone of the desired signal to the center of the bandpass filter.

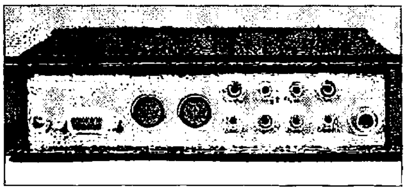

***Photo B**. Rear view (Photos by Tim Ciesielski.)*

You then narrow the filter and all signals outside the passband disappear. Disappear is the correct word. They are not reduced—instead, they actually disappear! You must adjust the level of the spot signal so that it doesn't get covered up by other stronger signals or so that it doesn't mask the signal you are trying to hear. This takes a few button pushes but is not difficult. Other brands of DSPs don't offer this spot feature. Without it you could easily eliminate the signal you are trying to isolate. It is a definite plus! The bandwidth can be adjusted down to 10 Hz. This is too narrow for normal CW operation—about 150 to 200 Hz is as narrow as you can go and not have the individual dots and dashes start merging. Don't confuse the ringing associated with typical audio filters. This filter doesn't ring. The best description I can give is that each dot (and dash) doesn't start instantaneously, but instead turns on and off slowly. At high speed and narrow bandwidth, it is hard to tell when one dot (or dash) stops and the next one starts. The 10 Hz bandwidth is useful for low speed CW in applications such as moonbounce where signals are very weak. If the speed is slow enough you will be able to discern the individual dots and dashes.

Even though you have adjusted the bandwidth as narrow as you can for the speed, sometimes there is still one station too close to the desired signal to be eliminated. For this situation the 599ZX has one more trick up its sleeve—it's called the tunable notch. This is a very deep notch that you can move anywhere to remove a narrow band of frequencies. You simply tune it until the interfering signal disappears. Of course, the notch center frequency is displayed on the front panel along with the bandwidth. For this feature the bandwidth is shown as a number from one to five instead of displaying the notch width in cycles. The manual didn't say what bandwidth corresponds with what number, except that one is narrow and five is wide. Advancing this number from six to nine results in a dual notch that has two notches that are 180 Hz apart. The manual claims that the dual filter is useful for eliminating interference from data signals. I don't know what data signals they're referring to, but there were two definite deep nulls as I swept the center frequency near the desired signal. The display indicates if you have the single or dual notch filter selected by showing an S or a D.

Tone reduction

This feature comes in very handy when someone decides to tune up on top of a voice signal. The Tone Reduction should be relabeled Tone Elimination since the tones are gone, not reduced! To check it out, tune in WWV on AM with the tone reduction off. You will hear the usual tone every second. Now turn on the tone reduction. The tones are gone! The same thing happens when you're using SSB and a tuner-upper comes on. All you hear is a very short ping when the interfering carrier comes on, and then no more carrier! Very neat! Just eliminating the tone is neat in itself, but there's always the problem of the receiver's AGC weakening the desired signal if the carrier is stronger than the SSB signal. The 599ZX overcomes this problem by using audio AGC to bring the audio back up to a constant level. It was really neat to be able to hear an S9 signal (before the carrier appeared) below a 10dB over 9 carrier! Imagine that the DX station you're talking to is running S9 at your QTH (not an uncommon level during this sunspot cycle minimum). All of a sudden a carrier comes on at 10 dB over 9. The S-meter isn't following the SSB station's voice because the carrier is stronger than the DX station's voice! You push Tone and the carrier is gone. You push AGC and the DX station's audio comes right back up to where it was before the carrier appeared. Nice, very nice! I have Variable Passband Tuning on my rig. With this control you can adjust the IF passband to reject an interfering signal. Sometimes it helps with an interfering carrier, sometimes it doesn't.

The tone reduction in the 599ZX always works.

Noise reduction

The Noise Reduction feature is not the panacea that I had envisioned. If a signal is weak, it definitely helps. Noise reduction is just that: The noise is reduced, but not gone. Most weak signals are made more readable when activating this feature. However, the signal must be just above the noise and not in it. The audio is a little more harsh (not distorted) when using Noise Reduction. However, if the audio is distorted, the noise reduction actually makes the audio worse. My guess is that the software doesn't recognize distorted audio as speech and removes parts of it, causing even more distortion (all the more reason to keep your transmit audio as clean as possible!).

I tried the noise reduction feature on 2-meter FM. Signals that were barely above the noise were made more readable. They too were made a little harsh-sounding by this feature.

I also tried the noise reduction on lightning static crashes. It did help some on SSB, but apparently there is very little you can do to fight those large bursts of energy.

AM line-noise reduction

This feature is absolutely amazing! I occasionally do some DXing on the AM broadcast band and even though power lines in our neighborhood are buried, I am sometimes plagued by 60 Hz line noise. This noise completely covers weak signals and is at best a minor annoyance on all but the very strongest signals.

To test this feature, I tuned in a weak signal on the AM broadcast band that had so much 60 Hz noise on it that spoken words could not be understood. Activating the AM Line Noise Reduction feature produced a perfectly clean signal. There was no sign of 60 Hz line noise. This feature is different from the Random Noise reduction described above. It can be set to either 50 or 60 Hz (user selectable) and only removes noise pulses at the selected frequency. The manual notes that this feature won't work on SSB, and it doesn't, but there's no explanation why.

Data modes

There is not a single mode but many different ones. They include RTTY, AMTOR, PACTOR, G-TOR, HF Packet, CLOVER, SSTV, WEFAX. I did not try any of them so I can't tell how much the 599ZX improves operation—but if operation in the other modes is any indication, the 599ZX will really help in these.

Test mode

This mode reconfigures the 599ZX into several different pieces of test equipment. They include a sine-wave generator, a two-tone generator, a peak and true RMS voltmeter, and PL (CTCSS) decoder/encoder.

"All you hear is a very short ping when the interfering carrier comes on, and then no more carrier! Very neat!"

The sine-wave generator produced a very clean sine wave on my oscilloscope. The level and frequency are both adjustable and are displayed on the LCD.

The two-tone generator produced the two tones that can be used for transmitter adjustment. The level is adjustable.

A peak and true RMS voltmeter are available simultaneously. The range is limited to 2000 mV (2 volts).

The PL decoder is an interesting feature. I connected the 599ZX to a 2-meter rig and began kerchunking the area repeaters (and yes, I identified with my call!). The unit will display the PL frequency in Hz and the level in millivolts. The 599ZX can be used to determine the PL frequency of a private repeater, providing that you can hear stations on the input or if the repeater transmits its own PL. The 599ZX can also generate PL tones. Since most VHF and UHF rigs now come with PL (some can even detect the PL frequency of the transmitter), the only uses I can see for this feature are (1) your rig's PL has failed; (2) you're using an old rig without PL (admittedly clunky and expensive—but it would work); or (3) you need PL to access a 10-meter repeater with your HF rig.

These features are interesting but I don't know where or when I would use them. However, they are there if you need them.

While I was shopping for a DSP I found out that one of the other brands offered an audio spectrum analyzer function when coupled to a PC. I would have expected the 599ZX to include this function since it is the most expensive unit available. I would definitely trade the AC voltmeter and tone generator functions for an audio spectrum analyzer. Most people have an audio generator, oscilloscope (to set the level) and frequency counter (to set the frequency), but how many of us have a spectrum analyzer? I have access to one at work, but most hams don't have one, either there or at home. I hope software upgrades will include this option.

Low-pass/high-pass filter

The filter high-pass and low-pass cutoff frequencies are individually adjustable. They were most effective when the low pass was set to 3000 Hz and the high Pass to 300 Hz. The manual said that they could be used in place of a SSB filter. I adjusted these controls in an attempt to reduce some of the interference from nearby stations when using SSB, but audio DSP is no substitute for a good SSB filter in the receiver's IF. My HF transceiver has IF shift and this does help in many situations.

DSP in the work environment

I work in an aerospace test laboratory where we do vibration testing, among other things. Vibration testing consists of putting the test item on a shaker (very similar to a speaker but much larger). The shaker is driven by a large amplifier (approximately 50,000 watts) over a frequency range of 5 to 3000 Hz. Vibration sensors are attached to the test item at locations where parts may go into resonance at certain frequencies. These sensors are not frequency sensitive and return signals from the vibration frequency, rattles, fuel or air passing through the test item and any other source of noise.

During testing we sweep the frequency of vibration over the 5 to 3000 Hz range. We plot the outputs of the sensors vs. frequency to see where certain areas or parts go into resonance. Very often the rattles, fuel and air noise completely cover the vibration signal. To filter out all this extraneous noise we use DSP tracking filters. They have a moving narrow bandpass window that tracks or follows the excitation frequency. Without them all we can see is noise—no signal is visible. With them we are able to identify very weak signals buried deep in the noise. At times the signal can be as much as 20 dB below the noise!

It's worth it

At $370, the Timewave Technology 599ZX is the most expensive of all DSPs available, but you're getting your money's worth and a lot more. The 599ZX has the fastest processing time, so there is no delay in output when you tune the dial. You listen in near real time (18 ms). The six memories are a definite plus—you can switch modes at the push of a button instead of having to adjust many knobs hoping that you have them all set properly. It is also very nice having all of the values and the mode displayed on a backlit window rather than trying to figure out the settings by looking at the pointer on a knob. The 599ZX has provisions for connections to two radios—a definite plus if you plan to use the DSP with more than one. There is no need to switch connectors—you just push a few buttons to switch radios.

I am very pleased with the DSP-599ZX. In several weeks it has enabled me to make DX contacts that would have been impossible without it. Other contacts that would have been difficult without it were made much more enjoyable. Every feature that I was able to test worked as stated in the manual. There were no operating quirks or compromises. The design and operation of the unit was well thought out in every area. For further information, contact Timewave Technology, Inc., 2401 Pilot Knob Rd., St. Paul MN 55120. Phone (612) 452-5939; FAX (612) 452-4571; E-mail dsp@timewave.com. Their Web site is at http://www.timewave.com. Be sure to tell them 73 sent you!

The Atlantic Cable

Have you ever thought you've *had a bad day?*

L. VanProoyen K8KWD
8330 Myers Lake NE
Rockford MI 49341

Cyrus W. Field had *lots* of bad days. Thirty-five years old in the 1850s, and already retired from a successful paper manufacturing business, Cyrus was aimlessly drifting through life when he happened into conversation with one F. N. Gisbourne. Gisbourne had earlier been involved in an unsuccessful cable laying project: installation of a cable from Newfoundland to New Brunswick, part of the circuit needed to link Cape Race (Newfoundland) to New York. Linking Newfoundland with New York would speed up late-breaking news to (and from) Europe by a couple of days, Cape Race being the last North American port of call for ships headed to Europe across the Atlantic.

Gisbourne was trying to resurrect his project (the undersea part, under the Strait of Cape Breton) with new money, and Field was a possibility. No one as yet knew how to bridge the Atlantic with a cable. As it happened, their conversation about money drifted to the more frivolous, settling on a discrepancy over the true distance between Newfoundland and Ireland. Cyrus considered the discrepancy trivial, but the conversation got him thinking, "Why not a cable all the way?" Armed with this idea, Cyrus soon launched into a twelve-year series of (mis)adventures that was to ultimately end with laying the first Atlantic Communications Cable.

Early submarine cable development

By the time Cyrus began organizing his cable-laying plans, considerable development of undersea cables had already been done by the British, driven by a desire to link England with the rest of Europe. They had the best facilities of the time for production of a suitable cable, as well as hard-earned experience and capability instructed through several failures in laying cable links between Ireland and England, and across the Straits of Dover.

The first successful cable-laying across the English Channel was completed by 1850, but the cable soon failed, suffering from abrasions caused by the Channel's gravel bottom. By 1853, the British had overcome most such problems with the development of a lead-coated, resin-insulated cable, as shown by the success of several operational links between England, Ireland, and the rest of Europe.

> ***"With over a million bucks spent, they finally had the strait successfully bridged by July of 1856. Only one problem—the Morse system wouldn't work!"***

Further reinforcing Field's plans was new information about the topography of the Atlantic floor, released by the US Navy. The naval survey revealed that the ocean floor along the proposed cable route was much more regular than previously thought, making the task of cable-laying easier than expected.

The Newfoundland and London Telegraph Co.

On May 6, 1854, Cyrus Field organized the Newfoundland and London Telegraph Co., Inc., with the aid of his friend, Peter Cooper, and other well-off New York investors. The company initially raised $1.5 million (and a pledge of support from Newfoundland) for starting their first attempt at laying an Atlantic cable. (At the time, they believed this money would finance the entire project... and that only one attempt would be required.)

Cyrus left almost immediately for England to initiate manufacture of the cable. This project went to mid-1855 when Cyrus, now armed with the wire he needed, turned up to lay the first section of cable.

Remember the Strait of Cape Breton?

Spanning this 55-mile stretch was probably an excellent introduction to how things were to go: The cable broke within two miles of shore, splices also subsequently broke, an uncooperative ship's captain had his own ideas of the proper route for the cable, and, finally, a storm forced the crew to abandon the project with over forty miles of cable down. Cyrus and company were forced to regroup for another try in 1856. With over a million bucks spent, they finally had the strait successfully bridged by July of 1856. The only problem? The Morse system wouldn't work!

Having started with little knowledge of communication systems just three or so years earlier, Field was rapidly becoming an expert in the subject. He was aware of earlier work in signaling by the Germans and particularly a system developed by the British Professor William Thompson (probably better remembered by his later title, Lord Kelvin). Cyrus adopted Thompson's system for the Strait of Cape Breton link and it worked. It was complicated, based on a sensitive galvanometer detector directing reflected light in a Morse-like code to an operator who in turn translated the reflections into text, but it worked. Cyrus hoped it would also work over a 2,300-mile cable.

The Cape Race to New York link was now essentially complete. That was the good news. The bad news was with only 2,300+ miles to go across the Atlantic, the Newfoundland and London Telegraph Company was bankrupt.

The Atlantic Telegraph Company of Great Britain

Cyrus had spent a good deal of his own money and a lot of his friends' getting this far, and his search for more "sports" in the US was being hampered by his critics. Undaunted, Field set off for England to gain additional financial support, and by the end of 1856, he had secured British backing of more than $2 million (a lot of money for the times) and organized the Atlantic Telegraph Company of Great Britain.

Back in business, Cyrus and his original friends (The Newfoundland and London Telegraph bunch) immediately set out to pick up where they had left off. By August, 1857, he pushed off from Ireland, laying cable toward Newfoundland. After four days and 350 miles, the cable snapped in two and half a million dollars went down the drain.

At this point, it was obvious that he needed a new cable-laying method. The scheme these guys came up with, though, was unique. They decided the best way was to use two ships, starting in mid-Atlantic, one headed for Ireland, and the other, Newfoundland, each paying out cable en route. Cyrus got it all going by mid-1858 with the two ships and all (he had to convince his backers this would work).

After several highly embarrassing experiences, both ships returned to Ireland to regroup. This was an occasion probably only Field the undauntable would have been able to handle. He had to reconvince his backers, and indeed he did. Underway again at the start of August, 1858, the two ships headed toward their destinations. Without major event, each ship reached its destination after six days. The Atlantic cable was in. But was it?

A hero's welcome turns to rebuke

In the first week of operation the cable worked well, but by the end of the second week of August, 1858, trouble began. In the meantime, celebrations were the order of the day for the "Atlantic Cable Heroes," the type of activities Cyrus Field was adept at promoting. The culmination of this hype was to be the exchange of messages between President Buchanan and Queen Victoria on August 16th, but by the 16th the line was almost dead. In spite of this, the messages got through (after two days of trying).

While the line continued to work to some degree well into October of 1858, word was spreading about the problem. The ensuing outrage that followed from both sides of the Atlantic resulted in Field's lying low for a few months.

After the dust had settled, Field and his backers decided to blame the problem on "faulty cable manufacture" which led to the premature failure of the cable (the "dust" had included allegations of fraud and the like). No one really knew what actually happened, but one thing they all knew was that they were broke, and new money was hard to get. Weeks ran into months and on into years with Cyrus out beating the bushes, trying to raise more money.

Field went on without success for over five years, both in England and the United States. The Civil War was raging throughout America at the time, and it, on its own, generated some interest in the need for a cable. But even the British at the time were reluctant to spend more money on the deal, having been recently burned by another undersea cable fiasco (in the Red Sea).

The Anglo-American Company

In 1860, halfway through the project, Cyrus W. Field had been forced into bankruptcy. He had consumed most of his personal fortune and that of his creditors on the venture. There came a time, during the nadir of his financial woes, that he became the object of ridicule and public avoidance. Nonetheless, he had persevered, making countless trips back and forth across the Atlantic to promote his cable project until he finally succeeded.

After seven years, Field was again on speaking terms with his old buddies at the Atlantic Telegraph Company and most of the other investors associated with his Atlantic cable project(s). As the Civil War was drawing to a close, he and his colleagues recruited the use of a passenger ship, the *Great Eastern*, for use in cable-laying for a year. By July of 1865, they were ready for another go at laying an Atlantic cable.

In the usual Cyrus W. Field style, they departed from Ireland after much fanfare. One thing he never learned was to avoid publicity, but with all the experience this bunch had, they *had* learned to continuously test the cable while en route. They were also using the latest in undersea cable design which, unfortunately for Field, still had several years of maturing to go. As cable defects were detected, they reeled the cable back until each bad section was located; they then repaired the defect, and continued on.

With all going well and about two-thirds of the distance traveled, they somehow lost the cable. Ten days later, they found it... only to lose it again, this time for good—or so it seemed. Cyrus must have personally known the coiner of "Try, try again," because off he went to London again, to reassure his backers that he knew what he was doing—and he did it; again, he organized a new company (the Anglo-American Company); he reloaded the *Great Eastern*; and headed for Newfoundland, although delayed almost a full year.

"Day after day, night after night, her great pistons glided in their channels, and the cable poured over the stern without a hitch. At last they had learned how it was done!" —Harlow, *Old Wires and New Waves*.

On July 27, 1866, the *Great Eastern* entered Trinity Bay, Newfoundland, still in communication with their terminus at Valentia Bay, Ireland. The cable was good. The cable was in!

Upon securing the July 27, 1866, cable, Cyrus turned the *Great Eastern* back to sea to look for his lost 1865 cable. Armed with better grappling equipment than he'd had the previous year, he found the 1865 cable on September 5, 1866, spliced it, and brought it ashore at Trinity Bay on September 8. This second cable worked perfectly, and the world now had *two* Atlantic cables. (Oddly, this stunt did more to restore Field's credibility than the docking of the July 27 cable.)

After losing an estimated $10 million over the preceding twelve years, Field eventually paid back all of his backers and investors, made money for everyone associated with the venture, and was then able to retire as a great world hero. By 1875, using the technology Cyrus W. Field pioneered, virtually every populated continent of the world was linked via cable.

TV/VCR Tuner Applications

Part Two of three—you may want to keep Part One, from last month's 73, handy.

Hugh Wells W6WTU
1411 18th Street
Manhattan Beach CA 90266-4025

Voltages developed for use with tuners must be regulated and heavily filtered to reduce noise and voltage variations. Noise and voltage variations can cause tuner frequency instability, since tuners are voltage-operated devices. Regulators such as the 7812 and LM317 work well in tuner power supplies.

The mixer and band control circuits operate on +12 volts. A pot attached to the +12 volt bus is used to provide an adjustable voltage of approximately +7 volts which is connected to the AGC terminal. The actual AGC voltage value is unique to the tuner and must be determined experimentally while listening to a signal. In operation, the AGC voltage may be varied with a pot and used as an RF gain control.

Tuner tuning is accomplished by providing a voltage which is variable from 0 to 29 volts. The 29-volt supply may remain fixed, but the voltage applied to the tuning pin of the tuner can be varied with a pot. The most satisfactory tuning resolution is obtained by using a ten-turn pot. The addition of a vernier knob to drive the pot is helpful. Even with vernier adjustment, the tuning can seem a little erratic. To smooth out the tuning action, a 1-µF capacitor may be connected from the tuning pin to ground. Although a larger capacitor value may be used, the voltage time constant could thus be made too long, allowing frequency adjustment overshoot should the tuning knob be moved too rapidly.

If the tuner has an AFT terminal, you can utilize the feature for fine tuning. If unused, the terminal must be grounded. To be used for fine tuning, the terminal may be connected to the wiper of a 5k pot. Voltage for the pot should be a low value not exceeding 2-3 volts. One end of the pot can be connected to a positive voltage and the other to ground or to -1 volt.

Construction

Fig. 1 shows the typical wiring and voltage requirements to support a TV/VCR tuner used as a frequency converter.

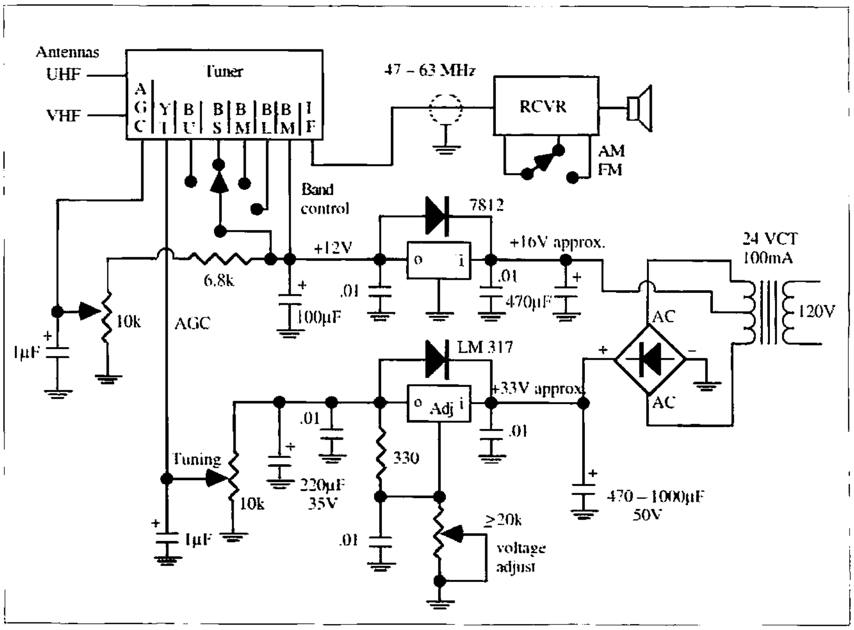

Fig. 1. TV/VCR tuner as a wideband frequency converter.

Mechanical construction is not critical, allowing a lot of freedom for the builder to choose the mounting of the tuner, pots, switch, etc.

Although the regulators are operating well below their dissipation rating, I suggest that they be mounted against a PC board or onto a small heat sink. The objective is to reduce the tendency for a voltage shift as a function of heat rise.

Dial calibration

After the converter is operating and the IF established at a specific frequency, a "look-up" table may be constructed to

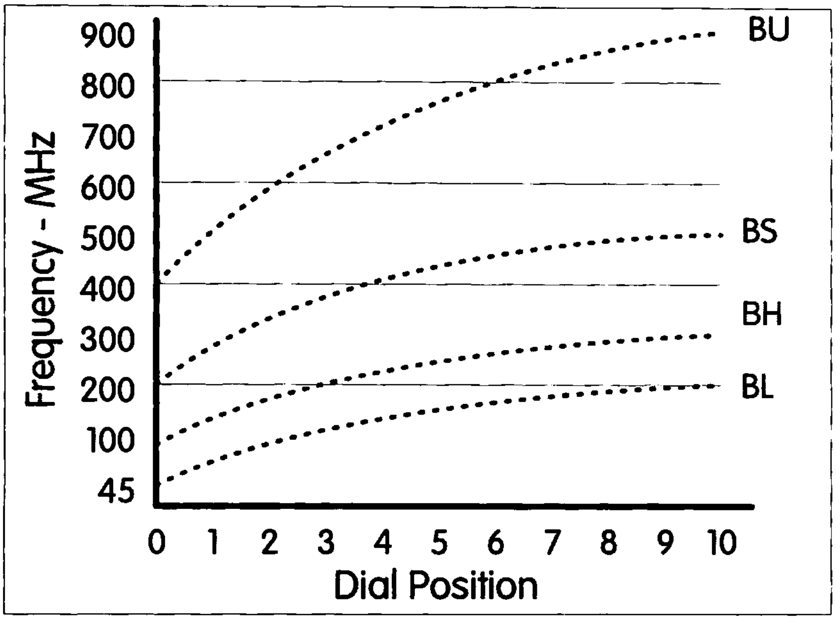

Fig. 2. Dial-to-frequency translation.

translate dial position markings to frequency. Specific frequency settings are then interpolated between known frequency calibration points.

Another method is to construct a calibration curve as shown in **Fig. 2.** Although the tuning curves are not linear, a straight line may be drawn between known frequency checkpoints. The readability resolution of the chart is set by the spacing between the X and Y coordinates on each axis.

Instead of using dial position markings on one of the chart's axes, you may use the tuning voltage for greater accuracy of frequency repeatability. TV/VCR tuners are quite reliable in their frequency resetability as a function of the tuning voltage. The use of a DVM to measure the tuning voltage to the 1st and/or 2nd decimal place is desirable.

If a signal generator is not available for determining frequency calibration points, known spot frequencies may be identified and logged. Signals such as cordless phone, FM BC, aircraft, public service, taxi cabs, ham bands, weather, TV audio channels and cellular phone can provide the necessary frequency references for rough calibration. In most cases it is sufficient to identify the band edges for each service.

"These tuners have one major drawback in mobile applications."

Take advantage of tuner availability—build a wideband frequency converter and tune in to the action taking place in the 45-900 MHz spectrum!

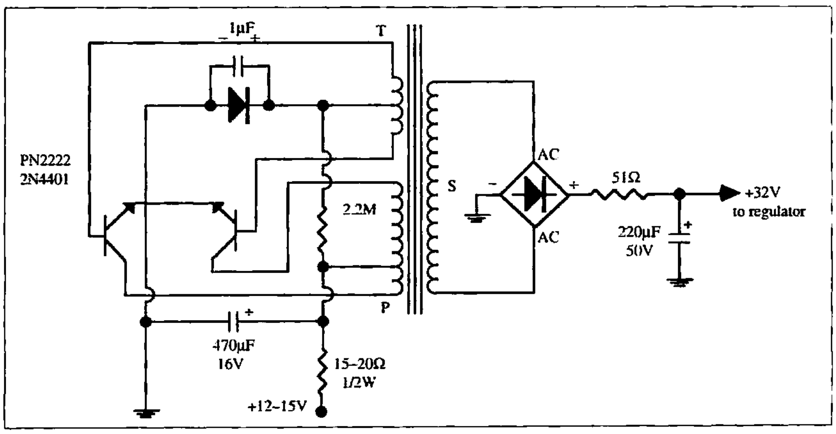

Fig. 3. DC-DC switching converter. All diodes are 1N4148. Operating frequency is approximately 56KHz. Transformer core: powdered iron, OD–0.4 to 0.5in., ID–0.125 to 0.150in. Windings: PRI–15T #26 enamel wound bifilar, SEC–30T #30 enamel, TIC–1T #30 enamel wound bifilar.

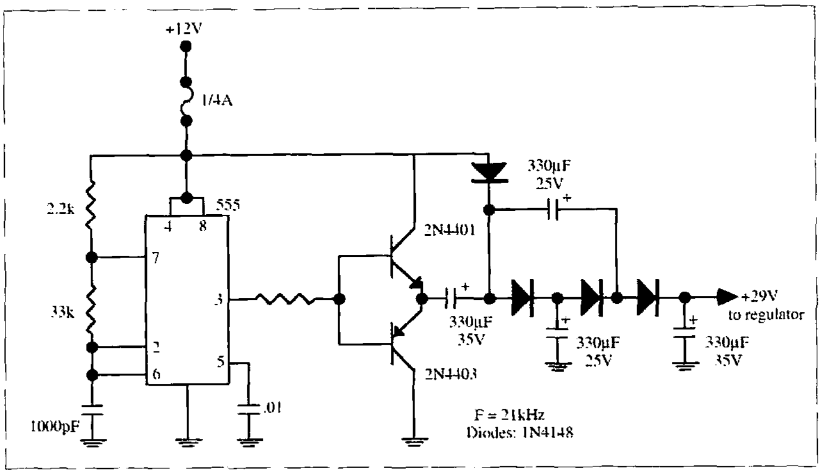

Fig. 4. 555 driving a voltage multiplier.

Mobile power

Because of their mechanical stability, TV/VCR tuners work very well in mobile applications. However, there is one major drawback that requires attention. TV/VCR tuners are voltage-operated devices and are not tolerant of changing voltage values. Therefore, mobile operation presents a real challenge for the experimenter. With semiconductors available, the challenge can be minimized.

The voltage requirements of a tuner are +12 volts and an ultra stable tuning voltage supply of approximately +30 volts. The +12 volts should be regulated because it is used to power the mixer/osc, band control and AGC circuits. Although most tuners prefer +12 volts, they will function without noticeable degradation down to about +10 volts. An automobile's electrical system is a suitable source and has a voltage value which can vary from about 12.6 to 14.7 volts depending upon engine speed. A standard 9 V to 12 V regulator could be used to provide stable voltage for tuner use except during the periodic loss in regulator headroom at perhaps a 12.6 V value when the battery terminal voltage falls. A simple zener diode regulator is normally sufficient and solves the problem nicely for the tuner.

The real challenge for mobile operation is the +30 volt requirement for the tuning voltage. There are several ways to generate a high voltage from a 12-volt supply. Two of the ways, a DC-DC converter and a voltage multiplier, are presented here. Perhaps the easiest method of obtaining the desired voltage is to build a DC-DC converter designed around a powdered iron core as shown in **Fig. 3**. Most any powdered iron core, except ferrite, will work in this application. Switching is accomplished by driving each transistor alternately into saturation. The core, being powdered iron, does not saturate easily. Therefore, the switching frequency is desirably high (approximately 56 kHz) in order to take advantage of a small core size and to aid in the ripple filtering process.

Another method of obtaining the high voltage is to utilize a voltage multiplier. But for a voltage multiplier to function, it must be driven with AC or a DC chopper circuit. **Fig. 4** shows a 555 IC used as a chopper driving a complementary pair of transistors. Working alone, the 555 cannot source enough power, but the transistors can. The transistors are driven from cutoff to saturation by the square wave output of the 555. There is little or no conduction overlap in the transistors, which results in little or no heat generation—therefore, a heat sink is not required.

With the AC voltage component generated by the chopper, the voltage multiplier will increase the output voltage to approximately 29 volts (which is marginal for tuning the high frequency end). It is difficult to obtain a higher voltage from the circuit shown, because only one voltage rail of the multiplier is moving, not two as would be the case with an AC source. Single rail switching limits the function to a maximum voltage multiple of three, minus losses.

Fig. 5 shows an LM317 regulator that is required to regulate the output of the +30 volt source. Adjustment of the regulator is critical in order to obtain the highest possible stable voltage. The correct setting is found during a battery non-charging condition when the source voltage is low. Pot R1 is adjusted to reduce the output voltage just enough to obtain output stability, which will occur when the voltage drop across the regulator rises to about 4 volts. Output voltage stability achieved by this method will be retained as the battery voltage rises/varies while under normal charge.

Because of mobile operation, all parts must be supported mechanically to prevent vibration damage. Heat-sinking, though, is not required since all parts are operating below their dissipation factor.

Next time: Spectrum analyzer, signal source, multifunction signal device. 73

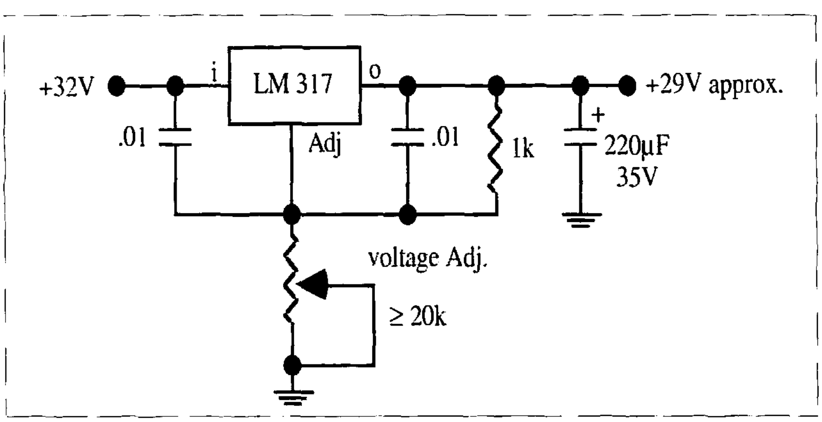

Fig. 5. 29-volt regulator.

Never Say Die
Continued from page 7

getting my 60-year membership pin next year.

Okay, now tell me where I'm wrong. Better yet, what do you propose be done and by whom to get our hobby growing like it is in Japan?

Bad Apples

A reader sent me a tape of K3ZO during a contest. What I heard defied all the accepted ideas of sportsmanship. Yes, this got me to thinking. What can be done about egregiously rude behavior on our bands? Jamming, bad language, and so on? Have you any ideas?

One basic problem is that when a nasty-tempered ham lets loose on the bands there are few, if any, repercussions. It is comforting to know that nasty-tempered people die much sooner than happy people, but they sure can spread a lot of misery while we're waiting for their nastiness to kill them.

Well, I tend to think in terms of solutions, so here's what I propose. How about *73* issuing a "Bad Apple" certificate to hams nominated for this award? The floor is open for nominations, so the next time you are assailed by some dirty rotten SOB on the air, why not nominate this turkey for this award?

Continued on page 49

Reviewing the Packet Scene: UK 1996

British Isles hams are ready to meet you!

Roger J. Cooke GB7LDI
The Old Nursery
The Drift, Swardeston
Norwich, Norfolk, UK
NR14 8LQ
G3LDI@GB7LDI.#35.GBR.EU

Obviously quite a few of you have read my article in the February 1993 edition of *Radio Fun*, judging by the response I've had by both packet and snail mail. It is gratifying to know that the UK packet scene is of such interest to our friends in the US. Many thanks for the comments and requests.

Some of the requests asked about packet addressing in the UK and whether a list of BBS was available. Updated lists are sent around the UK network every few months, and the amateur responsible for producing these lists is Brian G8ASO. He puts in a lot of work in compiling the lists and they are very useful. (*Ed. note: A copy of the current list may be obtained by sending a #10 SASE to UK Packet List,* 73 Amateur Radio Today, *70 Route 202N, Peterborough NH 03458 USA.*)

Just to explain the HR addressing: My full address is G3LDI@GB7LDI.#35.GBR.EU. Originally, we used an underscore and a number in place of the #35. Then we adopted a county coding. For example, I am in Norfolk, so that would have been NOR in place of the #35. However, to avoid confusion, and there was some, the # and a number representing each county was adopted. I see that this system is being used in other parts of the world, too. The subject of international HR addressing is an ongoing thorny one and an international standard would really be a great idea.

There have recently been lots of sysop messages debating the suggested change from the two-letter continental field to a four-letter one. This change was originally suggested by Tom Clark W3IWI, in order to avoid some of the anomalies that exist when forwarding intercontinental mail. However, there has unfortunately been considerable resistance against this change, especially over in Europe. Having been involved with HF forwarding since 1985, I thought the suggestions quite logical and a solution in some cases to the problems encountered in directing certain traffic. Convincing everybody that this is indeed the case is a different matter!

Using the BBS list should enable most to target mail to the county or area they desire in the UK. Obviously, if the full HR address is known, this won't be necessary. Targeting a bulletin, however, can be a real problem. There is a proliferation of @WWW bulletins, most of which are not relevant, or are out of date, by the time they reach the other side of the world. This problem can be helped with the use of the REDIST server for the FBB BBS. This server, written by Chris McMahon G6FCI, can provide four specific areas of coverage for a bulletin. These are *LocBBS*, *Local*, *Region* and *Nation*. The server has to be configured in the targeted BBS in order to work, but it is gaining popularity worldwide now.

LocBBS is the targeted BBS only. Local is a few BBS surrounding the targeted BBS, Region can be a larger area still, and Nation is obvious. The only disadvantage of this program is that a list of BBS with it installed, worldwide, is necessary to make full use of it.

HF forwarding and Satgate operation

With the poor propagation that we are at present suffering, my US link is only on 20 meters. I forward with Joe K1RQG, located in Bucksport, Maine, every day. This is the only Stateside link I have at present, but it is a good one. I have tried tests with West Coast stations, but despite good signals, the QSB on the polar route defeats packet totally!

If, for any reason, the HF route fails, then traffic for NA is sent up to Andrew

CLIVE DATA BASE COMMAND SUMMARY	
AFTER 30/03/91	Lists files installed on/after 30th March 1991
BYE	Quit working the CLIVE station
DOWNLOAD	Sends all selected files lo user
HELP	Sends this screen, as does ?
HELP AFTER	Sends help on the AFTER command
HELP HELP	Sends full help file for all commands
QTH	Sends information about the CLIVE station
SCAN XXXX YYYY	Search selected files for words XXXX or YYYY
SELECT 1, 2	Select files using file numbers
SELECT FT290	Select all files with the keyword FT290
STATS	Reports on contents of the database
TOPIC 3	Select topic number 3
TOPIC MODS	Select a topic by keyword
TOPICS	Lists what topics CLIVE has available
UPLOAD	Send msg lo disk (Leave a file/msg for SYSOP)
WHAT	Lists files in current topic
WHAT SELECTED	Lists all files currently selected
WHAT NOT	Lists all files not currently selected

GB7LAN in Lancaster for forwarding via his Satgate. This prevents undue delays occurring in NA traffic. I also run a Satgate, the second in the UK, and mail is split between us. This is how the mail is split:

GB7LAN serves the following areas *only:*
North America—NA NOAM
Central American countries—CEAM
Caribbean area—CARB
South America—SA SOAM
and parts of Europe via REQSAT server *only*—Iceland, Norway, Finland, Sweden, Denmark, Germany, Netherlands, Belgium, Luxembourg, Austria, Czech Rep., Slovak Rep., Poland, Spain, Portugal, Gibraltar

GB7LDI serves the following areas *only:*
New Zealand, Australia, Pacific Ocean—OC
Africa—AF AFRI by Satgate or HF if there is no Satgate route to the destination country
Asia—AS, ASIA by Satgate or HF if there is no Satgate route to the destination country
Middle East—MDLE by Satgate or HF if there is no Satgate route to the destination country

With the backup of my HF port, mail delays should be minimal, despite problems of propagation, and the mechanical and electronic failures that we all suffer from time to time.

There is another route to the US, also very fast, and that is the Lonny link. This is a New York/London wormhole. The New York end of the link is situated 66 floors up in Rockefeller Plaza in New York City. This link is provided by the NBC TV Employees Amateur Radio Club. The main sysop was Frank WA2NDV, who even named his dog Lonny! However, Frank has had to cease his sysop work and has now handed the torch to Tom NY2S. The Lonny node in Central London gives BBSs such as GB7HSN direct access into the US network. This enables users to have real-time connects with US nodes and even join in on-line conferences across the Atlantic. Access to the Lonny link is at 9k6 bauds. The sysop at the UK end of the link is Derek G1HSN.

UK linking

A lot of the UK linking is still at 1200 bauds, using two meters and 70 cm. However, there are several 9k6 links in place on 23 cm now, and experiments are being carried out by some on 64-kbit links. In Norfolk, we are at present setting up a full-duplex linking to the main local repeater by all the BBS, at 19.2 kbaud on 23 cm, to shift all forwarding off two meters and 70 cm, making life easier for the user. This is being achieved by the use of a very nice modem, capable of 38.4 kbaud, designed and built by Matthew Phillips G6WPJ and John Ferguson G8STW.

Licensing of BBS operation in the UK is also different. My GB7LDI packet BBS license is a variation on my full personal call G3LDI. We have to obtain a Notice Of Variation (NOV) to operate a BBS. Control of the issuing of these is maintained by the Digital Communications Committee (DCC) which was set up to avoid a proliferation of BBS operation, and also to maintain a negotiating body with the Radio Authority (RA), who control amateur licensing in the UK. Node licensing is controlled in the same way, and site clearance has to be obtained if unattended operation is required. These regulations are at present undergoing a complete review and the NOV is being rewritten. This will streamline the issue of NOVs and avoid the long wait that some have had in the past. In the UK, our two-meter and 70 cm bands are half those in the US, so a tighter control has to be maintained and band-planning is essential. There is a threat to parts of the 70 cm band now from the manufacturers of car alarms and security devices, which are being placed deliberately within the amateur band, along with commercial data links and radar. The sharing of the band is becoming a problem in which the amateur, having no vested financial interest, has little leverage.

By using the BBS listing you will now have a complete and accurate way to route mail to any part of the UK. Even if there is more than one BBS in a particular county, there should be no problem. Send it to any one of them and the correct home-BBS can soon be found. As long as you direct it to the correct county in the first place, this will save the sysop a load of hassle. However, if you have mail for Cornwall and you send it to a BBS in the north of England, the sysop then has to do quite a bit of research to reroute it.

CLIVE—a versatile database with a name!

CLIVE is the name given to a very popular database run by Colin G6WHL@GB7KLY.#19.GBR.EU

Currently the mailbox holds over 1300 files and is expanding weekly. You can obtain files from CLIVE with ease. First you want to know what files CLIVE holds which will be of interest to you, so you have to send a CLIVE REQUEST message to the database.

You have to tell CLIVE what TOPIC you are interested in. SELECT what part of that topic you want. You then ask CLIVE to send details on WHAT you have SELECTED. Then say BYE (control Z).

Example: If you want to know all the recipes containing either Chicken or Fish then do the following:

Connect to your local mailbox and type

SP CLIVE@GB7KLY

When "Subject:" comes up, type

REQUEST

When "Send your message, end with cntrl Z or /EX" comes up, type the following (on separate lines as shown below)

TOPIC FOOD
SELECT CHICKEN FISH POULTRY
WHAT SELECTED
BYE
^Z

It's that easy—CLIVE will send you a list of all recipes containing either Chicken or Fish.

The reason you SELECT CHICKEN FISH POULTRY is to cover any way that your subject may be stored. (Clive is clever and will sort things out to cover most combinations of your selection.)

The only lines you need to alter for any subject are:

TOPIC (the subject of your choice).

SELECT (the item of interest within the subject).

If you had chosen the TOPIC PACKET and SELECT BSX2 BSX

Clive would have sent you a list (and a few pointers to what you selected) similar to the one at the top of the page.

Now you can select which file you would like to see, so you have to send a message to CLIVE REQUESTing a file. You have to tell CLIVE the TOPIC (subject) from which you want a file downloaded. You then must SELECT the file

No.	Date	Bytes	Description of contents
38	18/08/90	7808	TNC2/BSX2 COMMANDS: A list of commands
39	31/08/90	4505	TNC2/BSX2 COMMANDS: A list of commands
40	31/08/90	4702	TNC2/BSX2 COMMANDS: A list of commands
45	17/09/90	3448	Modifying the BSX2 for STATE MACHINE DCD
48	01/10/90	1506	BSX2 DCD mod. The circuit diagram for file 45
92	03/03/91	3282	Linking DL and BSX TNCs for use as nodes
96	18/03/91	1030	BSX2 TNC mod for open OR closed squelch
CLIVE > BYE			
Thank you for using the database,			
I hope you find the reply useful.			
73, Colin, G6WHL@GB7KLY.#19.GBR.EU			

(or files) and ask CLIVE to DOWNLOAD the file (or files). Then say BYE ^Z.

OK, the TOPIC is PACKET and the file I want is the diagram for the DCD mod; if you look at the list above, that is file 48. So to download the file of your choice do the following:

Connect to your local mailbox and type

SP CLIVE@GB7KLY.#19.GBR.EU

When "Subject:" comes up, type

REQUEST

when "Send your message, end with cntrl Z or /EX" comes up, type the following on separate lines as shown below:

TOPIC PACKET
SELECT 48
DOWNLOAD
BYE
^Z

That's it. Clive will send you the file you have chosen. You can send for a selection of files with SELECT 48 92 96; there are currently 23 topics on the database.

Snippets

Other data modes are gaining in popularity in the UK. SSTV and FAX are used a lot, both on HF and VHF, using JVFAX, or something similar. Pictures can be made into BMP, GIF, or similar files and passed around on the air. Quite a few are to be found on the satellites.

TCP/IP is gaining in popularity, albeit rather slowly. There seems to be a tendency to shy away from this protocol, mostly because of a lack of information. To help with this situation, Ian Wade G3NRW has written a very good book, called NOSIntro, which explains TCP/IP

No.	Name	Content of Topics
01	BBSs	Bulletin boards & mailboxes on amateur radio
02	PACKET	Packet related files excluding BBSs
03	MODS	Mods to CBs, amateur, and PMR equipment
04	HUMOUR	Articles from Keighley ARS newsletter
05	SOFTWARE	Amateur related programs (sent as ASCII Files)
06	GENERAL	General interest—mainly for VHF users
07	VIRUSES	Description & cure of some common computer viruses
08	PRINTED	Writing, short stories, non-ham technical articles
09	COMPUTERS	Information and articles (other than programs)
10	REQFIL	1000s of files from UK BBSs via reqfil protocol
11	SPACE	Ariane, Galileo, Giotto, Mir, Voyager, Atlantis, etc.
12	ACORN	Acorn computers. BBC, Master, Archimedes, etc.
13	CLUBS	Clubs, societies, user/special interest groups, etc.
14	YAXPAK	News, previews, and reviews of the Yorkshire network
15	SYSOPS	SYSOP conference proposals, decisions, & minutes
16	ATV	Amateur television
17	LIFE	Views of life, the universe, and other things
18	MOBILE	Using/installing transceiving equipment in vehicles
19	LISTS	Lists for use with SCAN command, no download possible
20	MISCSOFT	Miscellaneous software—nontechnical
21	FOOD	A collection of recipes
22	ICOM	Modifications exclusively for ICOM equipment
23	YAESU	Modifications exclusively for Yaesu equipment

and also shows the user how to set up a system. It comes complete with a disk and is a good value for the money in the UK. I don't know if it is available in the US, but it would make a very nice present for any ham.

One of my HF forwardees, who visited me in the late 1980s prior to setting up his own BBS in Moscow, is Leo Labutin UA3CR. I forward every day with Leo, and have a very reliable path to him.

In Norfolk, UK, we have a yearly event on the last Sunday in June, the annual BBQ. It started off purely as a local packet BBQ but has grown over the last 8 years so that now we have over 100 people attending. It sometimes has an international flavour, too. John Bayes VK2SB, from Sydney, and Fred Wyatt VE7PL, from Victoria, have visited, along with their wives. If you are in the area of Swardeston, near Norwich, on the last Sunday in June, you will be most welcome.

High-speed data

Some experimental high-speed packet work is also going on.

Rob G1ZPU is currently working on a 10-Mbit (yes, *megabit)* 10-GHz link between GB7KHW and his system. Although the distance involved is only a couple of miles, it should be possible to prove the technology, leading to the possibility of linking hilltop sites at this unheard-of speed using simple and cheap equipment.

For example, the tx kit will work out at around £40, based on an ATV rx with mods for data. The rx will be nothing more than a cheap Amstrad or similar satellite rx which can be had for around ten pounds at the rallies. An LNB modded for 10 GHz rx will be about £30 (new) or £25 (secondhand). The rx will only need to have a baseband output for the raw video signal. For "video" read "data"! The communication medium is actually 4-wire ethernet. Speed can be anything from 1 Mbit/sec to 10 Mbit/sec. (100 Mbit would require modding the rx circuit even more, and also some serious tx mods, plus it's also pretty band-hungry, as the 10-Mbit link will want 20 MHz for a full duplex link—therefore, a 100-Mbit link will want 200 MHz!) Others have built 64-kbit links at 10 GHz for short point-to-point linking.

That just about brings you up to date with what is going on in the UK... 73 and happy packeting!

Is Your Mixer Circuit Mixing Like It Should?

It's not bad... it's just misunderstood.

John Pivnichny N2DCH
3824 Pembrooke Lane
Vestal NY 13850

Nearly every receiver, transmitter, transceiver, or transverter contains at least one mixer, yet this is one of the least understood circuits—and you will need to know about their operation if you want to build ham equipment. If you ask an old-timer how the mixer works, you'll probably get something about sum and difference frequencies. But what about the signal levels? What should they be? How can you measure them?

Amplifiers vs. mixers

Amplifier circuits routinely handle multiple signals by amplifying them equally without causing interaction between them. For example, two signals can be combined (added together) with a resistive combiner and then amplified as shown in **Fig. 1**.

Both signal a and signal b will appear at the output of the amplifier. If they are sine waves of different frequencies, then the two can be separated after amplification with frequency-selective filters. If the amplifier is operating properly, the two signals do not interact with each other. Each is amplified as if the other did not exist and no other signals are generated. In fact, if any other signal or noise occurs, it is frequently caused by improper operation of the amplifier, such as overdriving or flattopping, or by nonlinearities in the amplifier. The spurious signals generated by improper operation are called "distortion" because they distort the waveshape of the two signals.

A mixer circuit's purpose is to combine two signals so they *will* intentionally interact with each other. The two signals are multiplied in a mixer, while they are merely added in the amplifier circuit of **Fig. 1**. In a mixer, one signal is said to "modulate" the other. When two sine wave signals are multiplied together, additional frequencies are produced, consisting primarily of the sum and difference frequencies. See **Fig. 2**.

"Any other noise is probably caused by overdriving, flattopping, or nonlinearities in the amplifier."

Any circuit which partially or completely multiplies two sine wave signals will generate sum and difference signals of half the amplitude of the product of the amplitudes of the input signals.

All mixer circuits use this fact in one way or another. Practical mixers may do more than just multiply the input signals. They may provide some gain, output filtering, and "balancing."

The double balanced mixer

The two input signals of a mixer can be prevented from appearing at the output by means of a clever connection which "balances out" their effect on the outputs. A typical circuit for doing this is shown in **Fig. 3**. The circuit uses a well-known MC1496 double balanced mixer part. The inputs, labeled carrier and signal, can be applied as differential (push/pull) or single-ended (unbalanced) signals. For example, a push/pull carrier signal can be applied to pins 8 and 10 with .01-µF coupling capacitors. An unbalanced carrier signal would be applied to pin 8 with a .01-µF coupling capacitor and pin 10 bypassed to ground also with a .01-µF capacitor. The output is taken from pins 6 and 12 as shown. For operation from a 12-volt supply, the mixer is biased for 7.23 volts on the carrier inputs, 3.97 volts on the modulating signal inputs and 1.2 mA of current into pin 5.

The bias arrangement of **Fig. 4** is used. The outputs can be fed directly from 12 volts through an appropriate push/pull transformer as shown in **Fig. 3**. Outputs can also be fed with 3.9-kΩ resistors connected to +12 volts. The output signal is then taken from pin 6 or 12 by coupling with a DC blocking

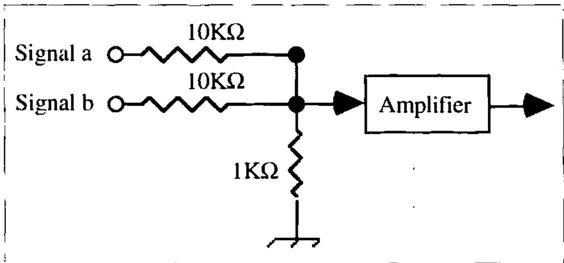

Fig. 1. Resistive signal combiner and amplifier.

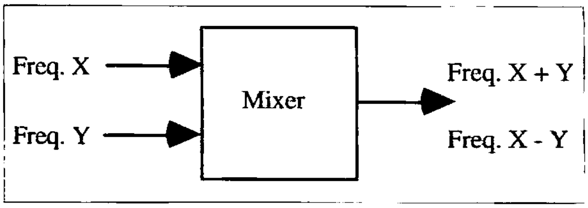

Fig. 2. Mixer diagram.

capacitor. For the frequencies in the HF range (3-30 MHz) a .01-µF capacitor is satisfactory.

Balancing of both the carrier input and the modulating signal input occurs because the collectors of transistors c and d are cross-connected to those of transistors a and b. If the circuit is working properly, only the mixing products will appear at the output terminal. Usually some type of filter circuit follows, to remove either the sum or difference frequency and allow the other one to pass through to subsequent circuits.

Test your mixer

How can you tell if this mixer is operating correctly? Suppose this circuit is used to mix a 5-MHz carrier with a 9-MHz modulating signal to produce a 4-MHz output in the 80-meter band.

You can check for a signal at the output with a sensitive wideband RF voltmeter. Some examples of RF voltmeters you can build are given in the references. The one shown in the photograph, known as a dBm meter, is available in kit form [reference 1].

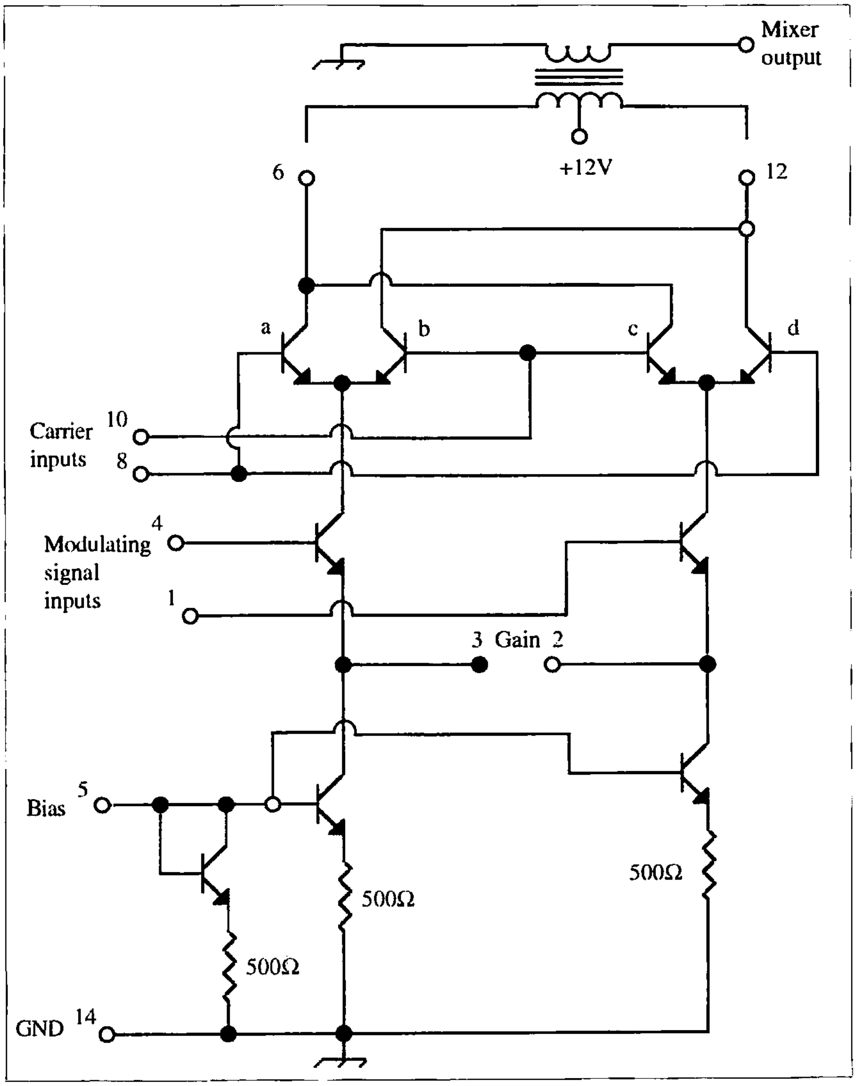

Fig. 3. MC1496 double balanced mixer circuit.

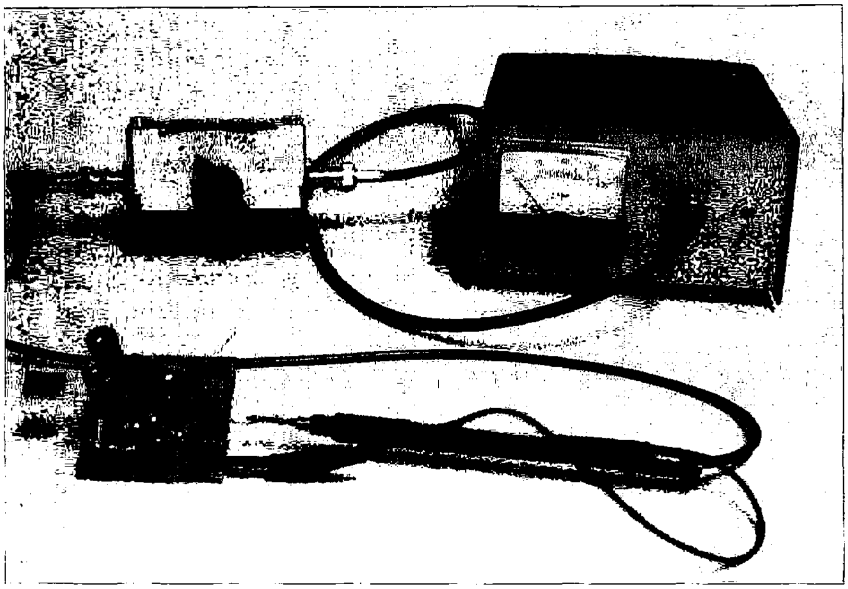

Photo A. Use of tunable filter ahead of RF voltmeter.

The first step is to apply one input signal (the carrier), and remove the other (the modulating signal input). There should be no signal at the output.

Just how weak the signal is at the output depends on how well the mixer circuit is balanced. A typical MC1496 part should have a carrier or modulating signal suppression of 40 dB or more. Temporarily unbalance the mixer by connecting a 10-kΩ resistor from pin 1 to ground. The output should jump up to a level two to three times the input level. Now remove the 10k resistor and the output should drop by 40 dB or more. For example, a 100mVrms output with the circuit unbalanced should drop to less than 1 mV when the 10k resistor is removed.

Now try removing the carrier input and applying the modulating signal. Temporarily unbalance the circuit by connecting pin 10 to ground with a 10k resistor. Check for an output signal and a drop by 40 dB or more as the 10k resistor is removed.

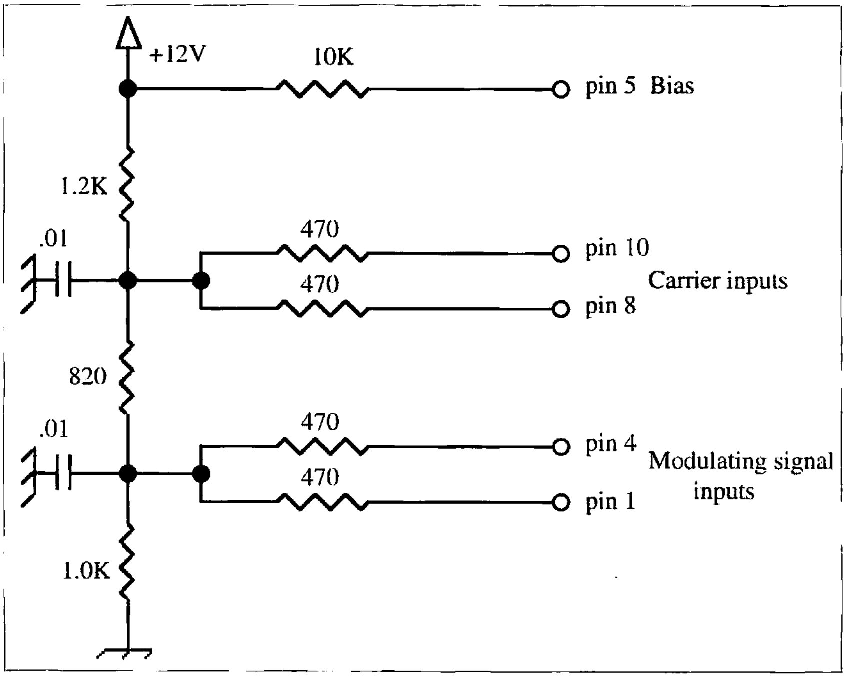

Fig. 4. Bias circuit for 12-volt operation.

If all is well so far, you have verified that the mixer is truly a double balanced one.

Now what about the sum and difference frequencies? Apply both the carrier and the modulating signals. You should see an output again with a level two to three times the level of the weaker of the two inputs, provided the stronger one is greater than 100 mV rms. But is this the sum or the difference?

Well, at this point it's both. One way to check is to use a tunable filter ahead of your RF voltmeter (**Fig. 5**). By tuning the filter first to the difference frequency (4 MHz) you can check its presence on the voltmeter. Then by tuning the filter up to the sum frequency (14 MHz) you can check for that, too. As the filter is tuned from 4 to 14 MHz, the level on the voltmeter should be at least 40 dB lower. This includes the fundamentals at 5 and 9 MHz, as well as harmonics (for example, at 10 and 15 MHz). Higher order mixing products such as (3 x 5) - (1 x 9) = 6 MHz should also be of low amplitude.

"You can check for a signal at the output with a sensitive wideband RF voltmeter."

Every mixer circuit should include or be followed by a filter circuit to select either the sum or difference output and reject the other. Typical amateur-quality filters will also provide at least 40 dB rejection of the unwanted mixer output frequency. You can also check this with your voltmeter and tunable filter.

Building a simple tunable filter

A basic tunable filter can be constructed using a single tuned circuit. It can consist of a high-Q toroid coil and an air-dielectric variable capacitor (**Fig. 6**). After winding the toroid core with the main tank coil, two link coils of two to five turns each are added to serve as input and output ports.

Almost any frequency range can be covered by selecting an appropriate core and number of winding turns. As a

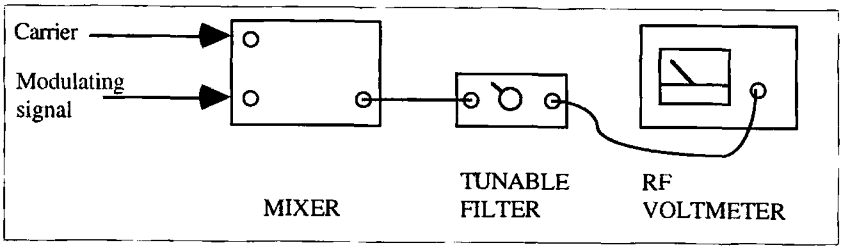

Fig. 5. Using a tunable filter ahead of an RF voltmeter.

convenience, an optional DPDT slide switch can be added to bypass the filter. Mount the whole thing in a small (3" x 2" x 1.5") aluminum box, using BNC connectors for input and output.

Calibration

You can mark frequency calibrations on the tunable filter dial by using a calibrated signal generator. Feed a known frequency into the filter and connect its output to the RF voltmeter. Tune the filter for maximum output and mark the frequency on the dial. Continue with other known frequency signals until the entire range has been calibrated. A dipper with a two-turn coupling link wound over its coil and connected to the input BNC jack can substitute for the signal generator if necessary.

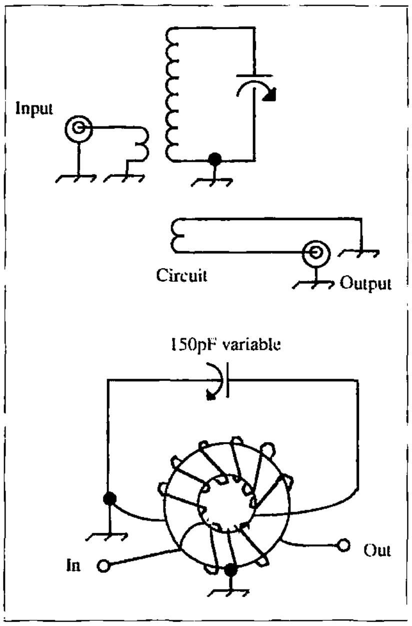

Fig. 6. Basic tunable filter circuit. For 7-20 MHz, use 38 turns #26 wire on T68-10 core. Links, 5 turns #26. For 22-60 MHz, use 10 turns #20 wire on T68-10 core. Links, 2 turns #22.

Other circuits

In addition to the MC1496, other double balanced mixers are the TL442CN, formerly known as SN76514, and the NE602. Single balanced and unbalanced mixers are also widely used—the only difference is whether or not the carrier or modulating signal is rejected at all by the mixer circuit itself. In a single balanced mixer such as the CA3028, one will be rejected.

With an unbalanced mixer such as the dual-gate 40673, neither input is rejected.

Both will appear at full strength at the output along with the sum and difference signals.

It's up to the filter following the mixer to reject all but the desired sum or difference frequency. As a minimum, at least 40 dB of rejection should be used.

Signal levels at the inputs and output should be checked to ensure that *only* the desired mixing product is passed on to the following stages in a ham transmitter or receiver.

A sensitive wideband RF voltmeter and outboard tunable filter are essential to perform the checks, but can be easily constructed at low cost. With these on hand a ham can verify or troubleshoot his mixer circuits with confidence.

Build a Half-Square DX Antenna

It's about as simple as they come. And it sure works!

William Van Tilburg KG8AN
5198 West Valley Circle
Portage MI 49002-1932

The half-square antenna is a gain antenna, yet it is one of the easiest, quickest types of antennas to build. This half-square configuration is a DX antenna that on 10m starts picking up signals from about 500 hundred miles out and gets stronger as the signals come from farther away.

The physical size is a full wavelength long, divided into three sections. You have a half-wave section on top, with a quarter wavelength dropped straight down on each end. To figure the length of an antenna you work a simple math problem. The formula is 1,005 divided by the frequency in MHz. This results in an answer for a full wavelength in feet.

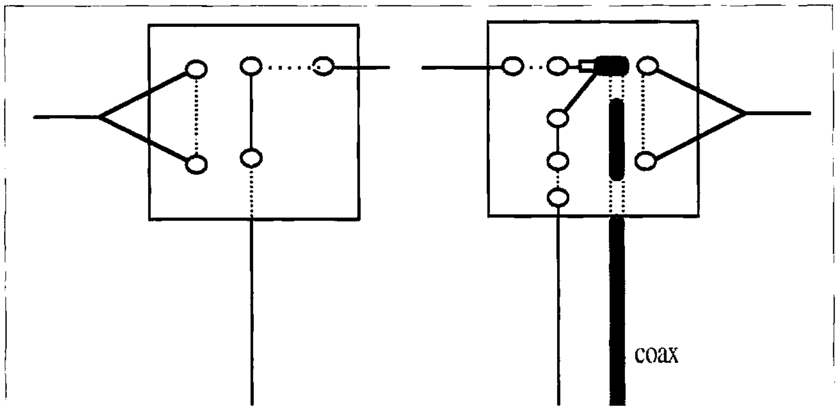

Fig. 2. Feeding the cable and wire through the pre-drilled holes will lock it in place with nothing but the force of friction.

Let's try a sample

First, let's go for the 10m phone section. The middle of the band I want will be 28.4 MHz, where the Novices/Techs can operate. That's 1,005 ÷ 28.4 = 35.387 feet of wire to start our antenna. That's 35' 4.5". You will need an extra three inches to allow for a small tie loop at the bottom end of the quarter-wave down legs. Each active quarter-wavelength is going to be 8.846 feet long (8' 10") so double the wire back to find the center and mark it with a piece of electrical tape. Next, you need to measure 8.846 feet out from our tape marker toward the ends. The down legs will also measure 8.846 feet, plus the one and a half inches for the tie loop.

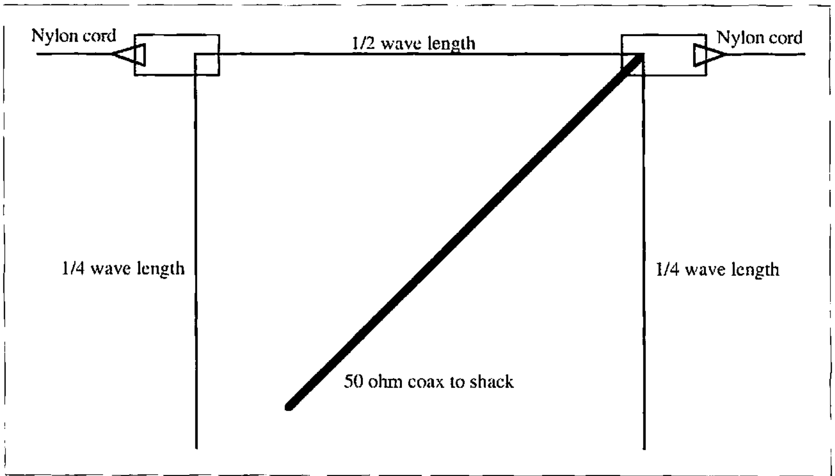

Fig. 1. The whole half-square antenna complete with insulators made from broken lawn chairs.

I have found that a broken white plastic lawn chair can be cut up to make very good antenna insulators. Cut rectangles 1.5 inches by 2.5 inches and drill holes as shown in Figs. 1 and 2. I use a covered wire about #16 gauge, which helps keep down snow static. String the half-wave section in one hole, over and through the second hole, and down through the third hole towards the ground. On the other end, cut the wire at the corner of the top and down leg. Feed the wire across two holes to lock it in place. The other quarter-wave wire is fed up from the vertical through the holes in the plastic to lock it in place as seen in the diagram.

Next, we need to feed the RG-58

through two holes to lock it in place; secure the center connector to the top horizontal section and then connect the braid or shield to the down leg as seen in **Fig. 2**. Next, string the nylon antenna support cord through the end holes to support it between trees, towers, or buildings. The connections of all wires need to be soldered and then taped for weatherproofing.

You need to keep the coax end of your antenna toward the transmitter and at right angles if possible from the top wire. Now pull your antenna up as high off the ground as you can get it.

The height of your antenna off the ground will affect its tuning. Remember, the higher the frequency, the shorter the wire will be. Shorten the wire top section and the legs to make the resonant frequency of the antenna higher. Make your adjustments about 1/2 to 3/4 inches at a time. If you change one leg by 1/2 inch, the top section will have to change by one inch. Make any required adjustments to find the center frequency and it's ready to transmit. Tie a loosely dangling retainer cord to each of the down leg loops to keep it from blowing over the top wire.

The maximum radiation is broadside, so an antenna strung north and south will do best to the east and west. I use this type of antenna at home on 10m, and also during Field Day on 20 from Kalamazoo County, Michigan.

Some of the half-square advantages are about 4 dB gain, a low radiation angle, good noise-canceling characteristics, both vertical and horizontal polarization, and low cost.

I've talked all over the world with this antenna, so be sure to let me (and Wayne) know how it does for you!

Editor's note: You can greatly simplify the trimming of the antenna if you cut it a little long to start, then find where it resonates (minimum SWR). Now you can make a simple ratio of the antenna length divided by the resonant frequency equaling the desired length divided by the desired frequency. This way, it takes just one trim session and you're in business without all that half inch at a time from each part of the antenna. For example, if you come out 8" too long, just cut 2" from each quarter-wave section—4" from the horizontal section and 2" from each vertical leg.

NEVER SAY DIE

Continued from page 39

Describe his offense briefly, and if you have a tape recording so I can join you in your condemnation, that won't hurt.

Perhaps the potential for public exposure and humiliation will help make our hobby more fun for us.

But, while we've an interest in cleaning up our bands by exposing the bad apples, we also should have a medium for rewarding the hams who are helping to make the hobby better. So I'll get busy on both Good Apple and Bad Apple Nomination Certificates. If you know any hams who have contributed positively to the hobby, please don't wait until they're silent keys to nominate them for the Good Apple Certificate.

If you are an artist or cartoonist (or know one), how about a couple of illustrations for the certificates? I need a really disgustingly bad apple drawing, and a good apple.

Now let's see what we can do to reward the good guys and humiliate the bad guys. And if you run into K3ZO on the air, please tell him "Turnips from Wayne."

The Code Again

A note from reader Boucton in France mentioned that France has decided to end all CW maritime transmissions as being obsolete. It is expected that the other European countries will follow suit. That pretty much leaves the use of Morse to a small group of aging amateurs. How quaint.

In a similar vein there was a mention in *The Old Timer's Bulletin* that radio pioneer Lee DeForest had always had an interest in amateur radio, but could never build up his code speed enough to get a license.

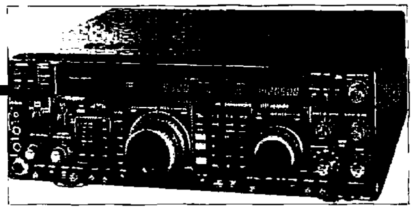
The Yaesu FT-1000MP Transceiver

Check out the "Big Rigs."



Richard Lubash N1VXW
E-mail: rlubash@poco.mv.com

This transceiver was introduced by Yaesu to commemorate the father of SSB communications, Yaesu founder JA1MP. The 1000MP combines some of the best of traditional radio construction (Collins filters) with high-end, high-tech, state-of-the-art design.

When I got the radio home I really wanted to try it out—I didn't want to spend time going through the 104-page user manual. Though I have since become good friends with the manual (a very well written and useful tool), I was able to get the 1000 on the air with minimal referral to it. The first thing you notice when you turn on the receiver is the sound. It's a big sound, quiet and full; not that traditional midrangy basic communications-type sound. After spending some time tuning around and enjoying the reception in both the CW and phone sections of the amateur bands, I took it for a cruise into the general coverage waters. If you're a ham who enjoys occasional SWL, here's a treat for you. The manual even turns you on to how to listen to a general coverage station with the main receiver tuned to one sideband and the sub-receiver tuned to the opposite sideband—with the combined output into a stereo set of phones... whew!

Receiver

The Yaesu 1000MP offers dual VFO reception with separate tuning and display for main and sub-receivers. Both receivers use quad conversion superheterodyne circuitry with three IF stages at 70.455 MHz, 8.215 MHz and 455 kHz in the main receiver and two at 47.21 MHz and 455 kHz in the sub-receiver. The tuning is accomplished through the use of Direct Digital Synthesizers driven by a TCXO master oscillator, resulting in extremely fine tuning with thirteen selectable tuning steps down to .625 Hz. Receive range is from 100 kHz to 30 MHz, with front panel selection of USB, LSB, CW, AM, FM, RTTY, and PKT.

Frequency selection on both receivers is available by direct tuning; a shuttle jog ring that allows large or small frequency change without cranking; individual amateur band keys with dual access to two user-defined sections and modes of each band from 160 to 10 meters; direct keypad input and memory selection from 99 regular memories; nine program limit memories or five quick memories. Memory can be configured in an almost unlimited variety of scanning options, and both VFOs can be modified in receive and transmit with a clarifier offset.

The QRM-fighting arsenal of the 1000MP includes individually selected cascaded second and third IF crystal filter banks, with 2400 Hz and 500 Hz filters installed and room for additional filters at 2 kHz and 250 Hz; an IF notch filter; IF shift and width controls and EDSP. EDSP stands for Yaesu's Enhanced Digital Signal Processing. This system works at the IF stage of the receiver and provides settings for random-noise reduction, selectable bandpass filtering with adjustable low and high cutoff skirts and automatic heterodyne notch filtering.

Transmitter

The transmitter in the 1000MP is capable of output on all amateur bands from 160 to 10 meters. The output power is adjustable to 100 watts in all modes except AM where output carrier power is 25 watts max. Output modulation include SSB, AM, FM and AFSK. The transceiver includes a high speed antenna tuner with 39 memories, and a full-function electronic keyer with multiple emulation types for the CW enthusiast. The EDSP used in the receiver is also capable of transmit audio enhancement utilizing four different voice equalization schemes.

Display

Yaesu engineers have left nothing to chance in terms of visual indicators for operating parameters. The 1000MP display has a fluorescent, multi-color, easy-to-read digital control panel. The tuning frequencies of both receivers are shown in large orange numerals. In addition, there is an expanded tuning scale that works as either an Rx, Tx clarifier tuning scale, or a tuning indicator for increments of less than 10 Hz. Separate S-meters for each receiver are bargraph digital type with the main receiver meter also incorporating RF power output, final amplifier collector current, SWR, speech compression, ALC, and DC supply voltage or microphone audio input level. If that's not enough metering, there is also a tuning scale that provides a center tuning segment for zero-beating CW stations and twin bars for mark and space tone tuning of digital modes.

Want more display? There are multi-color indicators for everything from HI SWR to external computer control. The Multi-Display window allows for a choice of memory channel frequencies, split offset or CW pitch. As a final touch, the sub-receiver, not having lighted mode selection buttons, provides visual indicators under the frequency display.

Front panel controls

The manual suggests that you familiarize yourself with the front panel controls and then goes on with seven pages

of short descriptions. This rig has all the knobs and buttons you will need to keep your twisting urges satisfied. Although the number of controls is daunting, the layout is logical and the silk-screened labels very readable (white against black). The left side of the rig has provisions for both .25-inch and 3.5-mm stereo headphones, a three-contact paddle/keyer input and a microphone. Concentric AF gain controls let you adjust audio output from both receivers and allow mixing into stereo phones in the dual reception mode. You can monitor your transmit RF audio, switch antennas adjust sidetone CW pitch and RF power from the front as well as all the standards: SQL, meter select, stepped AGC speed, mike gain, proc and a host of others too long to mention.

The receiver bandwidth module is controlled from its own silk-screened section of the front panel. Second- and third-stage IF filters, both factory installed and optional, can be configured for a wide variety of operating conditions. Both the 455 Hz and 8215 Hz IF stages have filtering selectable at (2nd stage) 2.4 kHz, 2 kHz, 500 Hz and 250 Hz; (3rd stage) 6 kHz, 2.4 kHz, 2 kHz, 500 Hz and 250 Hz.

The control cluster around the main and sub-tuning knobs allows for frequency and operational mode adjustment. The band keypad provides for direct frequency entry, or switching to any of the available amateur bands for the main and sub-receivers. The amateur band switching mode lets you select either of two VFO settings per band, allowing you to push once for settings in the phone section of the band and a second time for the CW or digital portions. Memory input and selection, quick memory, split and dual-channel reception are also controlled from here.

To the right of the front panel you'll find the controls for the EDSP, clarifier, notch, shift and width, noise blanker, antenna tuner and electronic keyer. I haven't included every control because as I mentioned the brief description section in the manual is seven pages long.

What's around back

As we all know, no matter what you see in the way of enhancements up front there should be an easy way to interface your transceiver to the rest of the shack. The 1000MP covers this need with a well-laid-out back porch. We start the tour with twin PL-259 selectable antenna jacks. These connectors are always used to feed the antenna for transmit, with or without the antenna tuner, and may be selected for receive function as well. If a separate receive antenna is used, it can be plugged into an RCA-type jack that is selectable from the front. Additional input/output provisions include: CW phone jack; RS-232 for computer interface; digital voice recorder in/out; packet; RTTY; linear ALC; audio in (AFSK or voice); external speaker; low level AF out for recording or amplifier input; ground; band data for external linear or tuner; +13.5 VDC out; transverter drive output; linear Tx/Rx switching and ground; 13.5 VDC input for external DC supply, and AC line in.

In the way of back panel controls the only two are a backup slide switch that enables power-off memory for the memory and VFO settings and a CW sidetone volume adjustment trimmer that I would have preferred as a front panel knob. Additional adjustments (11) are found by way of a top panel access hatch.

User configuration

One thing that stands out about the 1000MP is its ability to customize the transmitter and receiver parameters to almost any imaginable user preference. The rig comes with over 80 selectable menu options that are divided up into eight subsets. These sets allow for configuration of memory groups, shuttle jog ring tuning speed, IF shift width step, display frequency resolution, transmit audio tailoring, digital mode parameters, and electronic keyer configuration, to mention just a few. The concept here is "have it your way" and Yaesu has gone out of their way to make it so. As icing on the cake, the user button allows you to preconfigure a whole set of operating parameters so that you can switch to a mode such as RTTY or SSTV—with the touch of a button, all parameters for the mode are set.

Operation

The first time I had an opportunity to really get into the operation of the rig was, as luck would have it, a contest weekend. Although that did not allow for any leisurely DXing, it did give me a great opportunity to check out all the receive features that are so appealingly described in the manual. I found that the receiver, although offering a multiplicity of options for configuration, was very user-friendly and, with not much practice, I was able to sort the weaker contest stations from the general chaos found on 20 meters. The 2.4 kHz IF filters worked great, giving a nice clean SSB sound, though if you are thinking of using the rig for serious contesting the optional 2 kHz filter would be a plus.

I took the rig down to forty meters to give it a real interference workout and after first configuring the programmable menu for selectable auto or manual notch filter, I found some real nice heterodynes working on a station and kicked in the auto notch function on the EDSP. It performed like magic by wiping out the offending heterodynes with the push of a button. While I was down on 40 meters I thought I'd give CW a try. I switched to a dipole from the multiband vertical and gave a short CQ. I got a come back from KE4LRH in Richmond and had no problem cutting through the 40-meter QRM using a combination of the 500-Hz filter and the EDSP noise reduction. The electronic keyer was easy to use and had the nice feature of having the sidetone adjustment (pitch, as well as speed of code) on the front; a number of other keyer features are available through menu configuration. The QSK mode worked great and switching between transmit and receive was silent and instantaneous. I worked some more on 40 and then went down to 80 meters. The noise reduction and big quiet sound made copying a pleasure, even on the crash band. The transmit audio was judged very nice by a number of hams I talked to—all in all, the rig performed like a thoroughbred.

I used three different antennas, and the tuner met the challenge without a whimper even on a damaged G5RV. The basic feel of the tuning knobs and controls is one of quality, and the layout, though complicated, is logical and has what I would consider a relatively easy learning curve for such a complex piece of engineering. The 1000MP is a rig that would do the serious contester or DX chaser proud—but isn't too complicated for the ordinary ham who's into multimode communications and wants to step up to a big rig.

Thanks for the Memories!

The WB9KZY Island Keyer from Jackson Harbor Press.

Marshall G. Emm AAØXI/VK5FN
2460 S. Moline Way
Aurora CO 80014
75230.1405@compuserve.com

Designer Chuck Olson (the eponymous WB9KZY) was tempted to call this the "YAK," for "Yet Another Keyer." Fortunately he reconsidered, because the "Island" is a lot more than just another keyer.

Take a look at what memory keyers and kits cost in the marketplace. Here's a complete board kit for $21.95 that has four separate memories for a total of 500 characters, it's physically tiny (1.5" x 2"), and it can be configured to use less power than your average LED. It has straight-key input, a sidetone oscillator with selectable audio pitch, speeds from 7-48 wpm (set with a pot), and it will even tell you (in Morse) what speed is currently set.

This is a keyer that is physically small enough (and has low enough current drain) that you can mount it inside the smallest of QRP transceivers. Actual power requirements will depend on a number of options, but if you leave out the memory and the voltage regulator, it will idle at less than a microamp. On the other hand, it is so versatile that you may also wish to consider mounting one in its own enclosure as your "main" keyer. Several options are described in the documentation, and you are bound to think of more as you put it together.

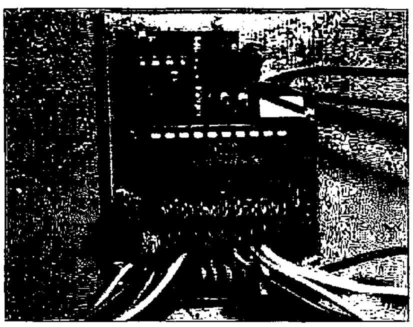

Photo A. Top view of PCB.

There are some features "missing," of course, but in many respects, especially the memories, it is way ahead of the Curtis 8044 series keyers, and costs less than most of the non-memory keyer kits! In his documentation, Chuck acknowledges a few shortcomings. Here they are—decide for yourself how important they are. The Island Keyer doesn't do contest serial numbering; weighting is fixed; it doesn't do automatic spacing, and it can be difficult to load the memories since there is no facility for editing them. Wait a... there *is* a facility for editing the memories. Just ask, and Chuck will send you a QBasic© program and instructions for using your PC to load the keyer!

OK, what about the other "shortcomings"?

Weighting is fixed? I see that as a plus. Standard ITU Morse 1:3 weighting is fine for 99% of us who routinely operate slower than 30 wpm, and generally acceptable up to the keyer's maximum speed. Besides which, variable weighting is not all it's cracked up to be—I had no end of difficulty in setting 1:3 weighting on another keyer kit I built. I've heard of people overweighting so that their keyer will sound like a "bug," but in fact what they are emulating is not good Morse—a properly adjusted bug driven by a competent operator should sound just like a keyer!

No automatic spacing? Who needs it? Again, if you change operating speed you have to change your keying methods anyhow, so why worry about the lack of a feature which just encourages sloppiness? And serial numbers are becoming less important as a keyer feature, because most serious contesters are already using keyboards anyhow, and many contests have dropped serial numbering from the exchange. No, I don't think there is anything of any consequence missing from this keyer.

Construction

When you set out to build the Island Keyer, you need to do a bit of planning, because there are so many directions you can take.

First, decide how you intend to mount it (you may need to drill mounting holes in the PCB, and that's a lot easier *before* you solder components onto it).

Then think about power—it's designed for 3-5V operation, and includes a 78L05 regulator. If you leave the regulator out you can power it with a couple of AAA batteries. If you power it with a 9V battery (or a 12V supply) you will need the regulator, but keep in mind that it will draw perhaps a milliamp itself. If you want, you can install a socket for the regulator, so you can pull it (and perhaps also the memory IC) for battery operation. Mine's set up as a stand-alone keyer, so I didn't worry about current consumption and in fact added a power-on LED.

Decide whether you will want to connect a speaker to the audio output. The output is adequate to drive a small speaker, and it is great to be able to check memory contents, speed, or even just to practice without keying a rig. As suggested in the manual, you may also want to add an SPST switch in the output (keyed) line to segregate the keyer from the rig. I included the speaker, and a volume control pot—in fact, I used a Radio Shack™ combination pot and switch, so that the one control would turn it on and set the volume.

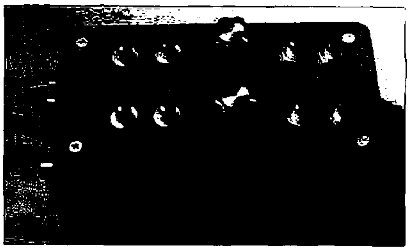

Photo B. Complete!

You should also decide whether you will want to connect a straight key, and if so whether you want the straight key to trigger the keyer or just go across the key line. The documented approach makes sense, so you can use the keyer as a code practice oscillator.

The rig requires 7 push-buttons. Radio Shack sells momentary buttons in sets of four, with two red and two black in each package. The color coding is handy, since there are four memory/send buttons and three function buttons. But what to do with the extra button? I simply put it across the key line as a "tune" switch.

Finally, if you ask for them, Chuck will provide instructions for adding in a simple delay timer based on a 555 timer chip. It requires one more pot and a couple of resistors and caps, but it is an easy way to set up the keyer as a beacon, or for repetitive CQ calling with a variable delay.

I'd suggest that you install wires for each of the off-board connections, even if you don't intend to use them. If you decide to add something later, it will be a lot easier to connect it to the existing wire than to try to connect a new wire to the board after it has been installed in a rig or box.

Building instructions are included with the kit, and if you have modest skills you will have no trouble in completing the project in about an hour. There is some tricky soldering involved, due to component spacing, so you will need to use a low-wattage iron with a fine tip, and work under a magnifier (or at least check each joint with a magnifier). Take your time, and watch for solder spatters and drips.

The two ICs (CPU and memory) are static-sensitive devices, so exercise the usual care in their handling—keep handling to a minimum, and make sure you are grounded: for example, with a clip lead between your wristwatch and a convenient grounding point.

I installed the completed keyer in a small plastic box with holes for the speaker in the bottom; the eight buttons and two pots on the top; and jacks for paddle, straight key, and output, along with an output toggle switch, on one end. You may want to use a metal box if you will be using a lot of RF power—the microprocessor may be susceptible to interference, but no problems were found in my QRP operating environment. The power cord exits from that end of the box and terminates in a Molex™ connector. Here's a handy hint for you: Calculate what size box you need, then get one that is half-again as big! No matter how carefully I measure and plan, I always seem to end up having to sit on the box to get the lid closed.

The smoke test

As you might expect with a kit having so few parts, there's not much that can go wrong if you did a good job of soldering. Once you've connected power (and assuming you've connected a speaker), just press the speed button—the keyer should send Morse numbers reflecting the currently set speed in wpm. Then connect a rig to the output and see if the keyer does, in fact, key. If connecting a rig is not convenient, just connect a multimeter across the output, set the keyer for its slowest speed, and observe a change in resistance as the circuit is keyed. Finally, check memory operation by loading a character or two into each memory, in accordance with the instructions.

If the keyer fails any of the above tests, take another look at component placement and examine the solder joints. And if you *still* have trouble, get in touch with Chuck at Jackson Harbor Press.

Operation

This is a nice keyer to use. It keys precisely, and doesn't seem to have much "feel." By feel, I mean operating characteristics that take some getting used to, so lack of feel is a good thing. But the ability to practice keying without connecting a rig is a real plus. Another feature is that if you connected a straight key jack to the straight key input (rather than across the output) you can use the keyer as a code practice oscillator and sharpen up your hand-pump skills.

The controls are simple—separate pots for sidetone volume and speed, and seven or eight buttons. Four buttons are devoted to the memories; one reports speed; one stops memory sending; and one triggers memory loading. As stated, on my version an eighth button goes across the key line as a "tune" button, and the volume control also serves as an on/off switch.

To load a memory, you simply press the load button followed by the button corresponding to the memory (1-4) you want to load. The keyer will respond with "?" from the speaker, and then it's just a matter of keying in the text you want to store. Automatic character and word spacing are enabled during memory load, so you can take your time. Press the load button again when you are finished, then the memory button to play back the recorded message. The total unused memory capacity can be considered as "available" to any unused memories, so, for example, memory one can contain up to 500 characters. Memory two can use all but the first 120 characters, and so on.

The Island Keyer is a lot of fun to build and a lot of fun to use, representing outstanding value for the money. In doing this review I spoke to Chuck personally, and found him very helpful as well as very interested in suggestions from users for a possible "upgrade version." One of the great benefits of programmed keyers, as compared with, say, the 8044, is that an upgrade will be just a matter of popping in a new chip.

Availability

The WB9KZY Island Keyer kit, consisting of circuit board and all board-mounted components, is available at a cost of $21.95 (+$2.00 shipping/handling) from: Jackson Harbor Press, RR1, Box 91C, Washington Island WI 54246. Phone (414) 847-2761; E-mail: [chuckolson@juno.com]. Credit card orders (only): (800) 238-8205.

Author's note: After reviewing this keyer, I found myself so impressed and pleased with it that it's also now available from my own company, Milestone Technologies. We also have available a "hardware pack" containing the necessary pots, knobs, switches, jacks, and a speaker. Our Web site is [http://www.mtechnologies.com/mthome].

On the Go

Mobile, Portable and Emergency Operations

Steve Nowak KE8YN/5
15475 Summerwood Avenue
Baton Rouge LA 70817

A few years ago, a friend of mine said to me, "Disaster communications isn't one of the reasons for the amateur radio service—it's the *only* reason! The radio frequency spectrum is too valuable to give to anyone just for hobby use, especially the number and different types of bands available to ham operators. The government lets us have these for support in disasters; if there's no disaster, go ahead and have fun!"

He was definitely right about the value of the radio spectrum. As we've seen recently, not only is there more demand for access to it, but also the government has found that frequencies can be sold for substantial amounts of money. We are privileged to have access to choice portions of so many bands. While DX, rag-chewing and contesting are fun, they do not justify the investment the government has in amateur radio frequencies. Amateur communications in support of disaster relief is one of the best ways we have to provide enough value to society to allow us to have one of the best playgrounds in this universe.

Naturally, there are other services which are positioned to provide similar support, and they will use such claims to justify expanding. Most public service agencies, such as police and fire departments, now have multiple radio systems. Cellular telephones are almost as common as cassette tape players in cars. These are often viewed as having eliminated the need for our traditional role. Fortunately, amateur radio does provide a number of advantages over other services, and acts as a significant augmentation to the communications services used in daily public service operations.

Portability

The days when an amateur station was a large tube-driven stationary system are long gone. Hand-held and mobile units predominate in the VHF and UHF frequencies, and there are so many 2-meter and 440-MHz repeaters that the frequencies have to be coordinated. Most modern HF rigs can be carried in one hand and powered from an automobile battery/alternator as well as from a 110-volt to 13.8-volt power supply. An amateur station can be quickly set up in a location which has inadequate or non-operational communications. This means that a shelter set up in a school gym can be quickly plugged into the emergency network.

"Cellular telephone systems can get overloaded in normal usage; in emergencies they jam up."

Multiple simultaneous contacts

While cellular phones have grown in popularity, they do not lend themselves to disseminating certain types of information. Since each intended recipient must be individually contacted, multiple calls must be made for each message. With amateur radio, all stations on a given frequency can be simultaneously made aware of the same information. Frequencies can be assigned to allow one network to provide general communications, another for command functions, etc.

Training

It seems that almost everyone these days is as comfortable with the Internet and World Wide Web as they are with the telephone. However, not everyone is as comfortable with taking detailed messages as hams are. More importantly, a well-run, properly disciplined network will less likely be jammed by would-be users. Cellular systems, on the other hand, can be overloaded during normal operations in some areas, and have significantly higher usage during emergency situations.

Coverage

Although not every repeater has long-term battery or emergency power, usually there are adequate reserves to allow for initial operation. After these reserves are exhausted, it is possible to set up portable repeaters or arrange for auxiliary power for the repeater. For wider area coverage, the high frequency bands can be used to permit longer distance communications. And, when all else fails, it is possible to utilize the old-fashioned method of relaying messages.

Cross-coverage

Because of the portability of amateur radio, and the range of frequencies available, hams can act as a bridge between various agencies. In many cases, police department radios may not be able to communicate with the fire department, or neighboring police departments; the Red Cross frequencies are different from both; and the National Guard uses military frequencies which are different still. Amateur radio operators can be stationed with the communications people of other services and pass traffic from one service to another. Likewise, it's not unheard of for a ham stationed at a police or fire dispatching post to spend 90% of his or her time backing up the dispatchers on their equipment and 10% on the ham bands.

The price is right

The government agencies which the amateur service supports receive this support at no cost. As amateurs, not only are we expected to provide emergency communications, but also we are prohibited from being paid. In addition, we show up with our own equipment! It would be tough to find a better deal.

Enthusiasm

Let's face it, in an emergency situation requiring the support of ham operators, we tend to show up charged with a healthy dose of adrenaline. Amateur radio is one of those special hobbies which gives us the chance to make an important contribution to our community. In doing so, we are using many of the same communications tools and techniques that we count as fun on other days. In my experience, when the call goes out, the response is overwhelmingly positive.

Diverse talent pool

Hams represent a fairly broad spectrum of talents. Sometimes these other talents allow assignment of people to locations where they can really hit the ground running. Hams with health care backgrounds, for example, can be assigned to hospitals; those with a military background are a more natural fit for the National Guard. It is amazing what some hams are capable of doing. During the aftermath of a tornado a few years ago, I was impressed by the extreme smoothness of the net control operator. He kept track of everybody's name, callsign and location, better than I could have with a computer. Later I found out he was blind, was used to keeping all these facts as mental notes, and had no need to refer to anything to refresh his memory.

There are lots of possibilities for the amateur community to provide key service in an emergency situation. However, this is not an automatic guarantee that hams will be ready, willing

and able to follow through. There is also no guarantee that our services will be welcome. If you were a mayor or a city manager facing a crisis, would you realize that amateurs were a resource at your disposal? How would you let them know they were needed and coordinate their activities? A lot of work needs to be done before the need arises, but fortunately most of the work is fun, interesting, and more satisfying than exchanging RST, rig and antenna information.

This column will explore a number of different aspects of emergency communications. Since there are many excellent organizations throughout the country, I'll try to get different viewpoints on what works well. We'll explore network operations, different types of equipment, setting up portable stations, coordinating amateur activities with local government operations. Likewise, we'll look at the types of emergency service support required in different situations. What's needed for SkyWarn weather spotting is different from what is needed following an earthquake. Winter storm situations place a different demand on operators than a hazardous spill situation. We'll also look at managing an operation—while the response in the early stages of an emergency is strong, how can we maintain that response days or even weeks later?

"Amateur radio gives us a chance to make an important contribution to our community."

I hope you'll find this column fun and interesting. If you've got ideas, please feel free to send them either by E-mail to 74640.1442@compuserve.com or by snailmail to the address at the top of this column.

NEVER SAY DIE

Our Story

Time was when I'd get several ham-promoting newspaper clippings a week from readers. Now, it's rare. Sure, I've tried to sell the idea that every ham club should have a PR officer whose mission is to make sure that meeting notices are published in the local newspapers and provided to local radio stations, but even more important, to make sure that any club or member activity that provides a possible excuse for newspaper, radio or TV coverage is exploited. Field Day? Get a story and photos to the newspapers before and after the event. Any emergency services ditto. If there's a local school radio club get the story into the papers. If someone in the club makes DXCC or wins a contest, get photos and a story to the papers. We need visibility and we need it desperately.

My thanks to Ed Lappi AE4EC for sending a copy of the Chapel Hill *Herald*, where there was a full page story of the local school radio club. But I should be getting clippings like that every day, not once every few weeks. Get on the stick, clubs.

Talk Radio

Back in the '50s Jean Shepherd K2ORS got started in radio broadcasting in Cincinnati, as I recall. Soon he had a nightly show on WOR, clear channel 710. He was on from around 11 pm until 5 am nightly. This was not talk radio as we know it today. Jean just sat there and talked for six hours a night, with no call-ins to take up the slack and no guests to interview. And Jean built up one heck of a following. Then he got into writing, with a bunch of prize-winning stories published in *Playboy*, a series of great books, and eventually he wrote a string of wonderful movies.

He was followed on WOR by Long John Nebel, who brought in guests to interview and built a huge audience by getting into the weird stuff. These days he'd have contactees and such.

And that's pretty much the Art Bell W6OBB formula. He's on nightly from 11 pm to 4 am PST on over 300 radio stations. Some only carry his program for three hours. The only station I can hear well is WTAM in Cleveland on 1100 kHz, and they only carry three hours. Art interviews some very interesting people, plus he also lets the audience call in to ask questions and make comments. He gets into very weird stuff at times.

I keep a little radio beside my bed and, if I happen to wake up during the 2-5 am slot, I check to see who he's got on. Just in case he has something I wouldn't want to miss, I set my video recorder with the radio input to the audio jack, and record the three hours every night. Well, it's something to listen to while I'm opening my mail, and these days that often takes an hour or two.

Check the broadcast band some morning and find out which station brings in Art's show best for you. And every now and then you'll hear *me* being interviewed.

My interviews on his show have resulted in letters from listeners in all 50 states, Puerto Rico, the Virgin Islands, and even Israel and UK. The last two are from an Internet "broadcast" of the show.

I've got so many things to talk about that sometimes I think about having my own show. But something like that ties you down, and I still have a bunch of countries I want to visit that I haven't seen yet. So I'll have to make do guesting on talk shows. But if I were to do my own show it would be different from any other I've heard. My aim would be to get people excited about improving their lives. About getting healthy. About making money. About self-education. About making our lives better through a much smaller government. Through re-inventing our school system. About eliminating poverty and the drug problem. Making prisons less of a growth industry. Well, you know, all those things I've been writing about.

But, would it sell? Probably not. Heck, I haven't been able to get *you* interested in living longer or getting healthy, so perhaps I'm just spinning my wheels.

Sure, you want me to write about amateur radio. Fine. But when I ask you to write and tell me about the most exciting times you've had with the hobby I get *bupkis*. Ham radio has provided

Carson City NV 89703

How to get the most out of your local PBBS

Would you like to get better acquainted with the strictly-for-hams bulletin boards and stay posted on such hot items as DX propagation, AMSAT information, the latest from the FCC or what your local club is up to? You can also hunt for bargains for your ham shack or clear out some of your own clutter for cash—there is a continuous swap meet in progress and you can visit it from the comfort of your shack. Plus, there are no membership costs, and it is available 24 hours a day.

You will be well rewarded for the time you spend getting to know the ins and outs of your local ham packet bulletin board system (PBBS). If you have been letting this exciting technology pass you by because you just didn't want to learn another new thing (and it looked expensive), getting started is easy—and can be accomplished on a budget. And you'll have fun learning something new, and that is what a lot of ham radio is about.

Learning experience

I strayed from the norm a little and was exploring the node portion of the local system. In the *Just Heard* category, there were about a dozen callsigns, and one of them had a "-1" extender on it. I thought it would be fun to leave this ham a message in his mailbox—hardly anybody gets personal mail that way.

I was connected to the node okay, but my attempts to connect to the ham station were continually rebuffed. The command [c kb7xxx] just wasn't recognized. As they say, when all else fails... I remembered, once again, why I go to the effort to download the user manual from the local node/bulletin boards when I first get acquainted with a new one. The user manual spells out the steps to take. It is necessary to designate the port number on this system to make the connection and *presto*! There I was in his mailbox. A few days later, I received a nice note on the PBBS after he found the message. I look in on the PBBS frequently as it is a good source of recent happenings both locally and across the country.

So how do we overcome these little frustrations? Unless you have psychic gifts and can read the mind of the person who wrote the software, the easiest method I have found is to read the manual for your local PBBS.

Where do you get it?

Every bulletin board I have seen has a user manual readily available for download. Most of the bulletin board systems have more than one function. In the case of the local system, there is a node available for connecting to other digital stations in the area or to other nodes. The node, in its simplest form, can be thought of as a repeater. The node has a different identifier—I can connect to it by telling my packet station to connect to CARSON. Once connected, a series of commands is available (see **Photo A**). These commands are similar, but not related, to the commands of the BBS.

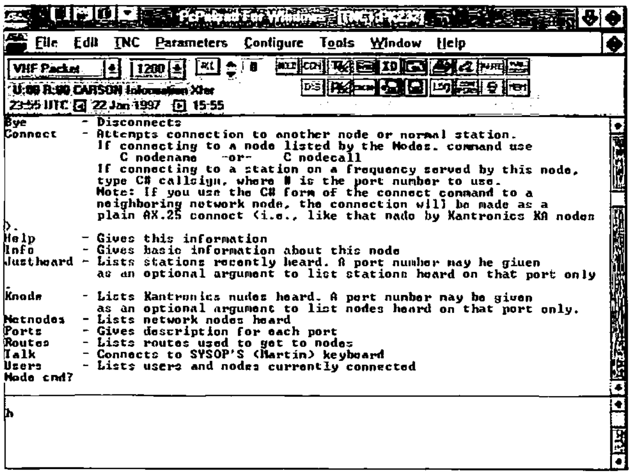

Photo A. Opening screen to node. A series of commands were listed after hitting Enter on a blank screen. One of these was Help. I merely typed the "h" in the lower "transmit" box, hit Enter, and slightly more than a screenful of instructions scrolled up the screen.

The bulletin board (PBBS) can be connected to after connecting to the node, so you can think of them as individual stations on the same frequency doing different jobs. If they are both busy, though, the throughput will be reduced because they follow a polite protocol and wait for each other to finish before they proceed with their particular task.

Intermingled with this is another function, the database. Your PBBS operator (sysop) has a computer dedicated to this entire operation and you have access to many files residing on his hard drive. One of these will be the user manual.

On the local system I found my user manual by typing the "W" command (**Photo B**). "W" is a pretty standard command used on many systems and it translates simply to What [is there?]. You will get a listing of the files and subdirectories of the database. In the local database, there is a file, USERMAN.DOC, and when I downloaded this I got a 24-page text of how to use the PBBS. You'd better believe that I printed it.

If your system does not have a "W" in the command line, type "H" for Help and it will reveal an abbreviated list of what all the commands can do. If you do not see a hint of where you might find a manual, send the sysop a message and tell him you are an avid reader and need this information for your library. He will tell you how to get it.

I learned, once again, how helpful and encouraging the ham community can be, when I first committed to enter the digital spectrum. I reside in an area where it's very difficult to make good solid contact with any VHF node, because this valley is surrounded by real mountains. That plays havoc with line-of-sight communications and especially with packet where the strings of information come in fairly long bursts.

To understand why that is a problem you need to understand a phenomenon known as multipath. You can work FM repeaters all over this neck of the woods and the multipath, though it exists, has little effect. With a packet transmission, however, it can be a disaster. Regardless of the power, if the signal bounces off a mountain, the received signal hits the antenna two or more times and turns the data string into mush—and software just can't decipher it.

A few years back, the closest PBBS was on the other side of the mountain. A direct connection was difficult to establish and nearly impossible to maintain. Transferring intelligible information was hopeless. I solved the problem for a time by setting up a digipeater out in the middle of the valley. It consisted of an IC2AT and an MFJ 1270 with a Commodore 64 to load software and monitor the activity.

This worked but it was slow and it was buggy. I frequently had to trek across town to reset the TNC, a great experience, because when you exercise the gray cells they get stronger—and I felt I had overcome the evil multipath demon. After a few years, I had to take the system down; it was at my business location and I decided to stop doing business. It was the best decision I made in years, but I was virtually out of packet radio.

To the rescue came a local ham who set up a PBBS, right in the line of sight I needed to regain access to the packet bulletin board system, and without having to go through two repeating processes. Working packet is now the pleasure it should be.

Those of you who use services such as CompuServe, AOL, and the Internet take a lot of this transfer of information for granted. The on-line services store and move massive amounts of data in

all forms, including text, graphics, and sound, accurately and speedily down the phone lines.

The amazing thing about this is that, except for the speed, we can do all this via our radio connections. That's right: Most of the data passed through the packet radio system is in basic text format with no fancy fonts, and the pictures, if drawn, are done with keyboard symbols. However, it is possible (and some hams are doing it) to move binary files such as word processor data, graphics, and even sound files through the packet system. And one day, maybe even the speed bumps will go away.

There is quite a proliferation of ham bulletin board programs, so it would not be reasonable to attempt to list all the variations of commands and what they do for each system. Here I find a command line listing with 21 of the 26 letters of the alphabet—and that's just the beginning. When you get the inside dope on these commands, many of them are combined with three or four other letters for variations of the command to help you become more efficient.

"A" is a nice simple command that stands for Abort the operation you have in progress. They can't fool with that. "B" is another common no-brainer that allows you to disconnect from the PBBS. Now "C" becomes another story. On a node it is used for connect, which seems straightforward enough. The system I am working into has some variations. If I were connected to the node and wished to connect to another node or station I would normally type in [C callsign]. This system requires a port number after the "C" and then the callsign.

When I connect to the PBBS, that "C" is another story. It then stands for conference. Well, not very many keyboard conferences are held, but there *is* a way and I guess this double use of letters just shows that we don't have enough letters in our alphabet.

Photos A and B are screen captures so you can have a look at my screens as I use my current (AEA) computer program. There are many good programs on the market these days. The best way to get comfortable with software is to find a neighboring ham who'll show you what he is using. If it looks like something you can handle, you have a built-in tutor. The next best is to jump in and figure it out on your own. It's not as difficult as it may seem.

If you are looking to get the most bang for your buck, there are several factors to consider. If you are going to concentrate on packet for the foreseeable future, several choices are available, including MFJ, Kantronics, BayCom and PacComm. If you can come up with a used TNC and need software, there is a good selection of packet software that won't put you in the poorhouse. You can buy all new (except for the radio) and get into packet these days for $50-150 (more about that part next month).

Hams use programs of all kinds, from telephone terminal programs to a variety of dedicated programs, such as the one I am using; they all tell the packet system at the node or PBBS the same commands. The fancier systems use the power of your computer to accomplish keyboard shortcuts so you can get on with your hamming and not spend all your time typing in commands.

Communications software used in ham radio isn't the same as in word processors or following hypertext links around on the Internet. This stuff forces you to get a little more involved. By that I mean it won't let you get away with a thing. If you want to use your computer for ham communications, at least study the operational commands and keep a list of them handy when you are making contact. When you first use any program, it is helpful to keep a few notes close to the keyboard until you get the hang of things.

As you may guess, the modern programs are equipped with help windows for ready reference, so you can usually look anything up within a half minute. In fact, it appears the entire instruction manual is contained in the help files, all categorized alphabetically. It is usually faster than finding the correct page in the hard copy manual.

I have occasionally had to eat a ration of humble pie for not remembering a command in the middle of a live contact on HF. If

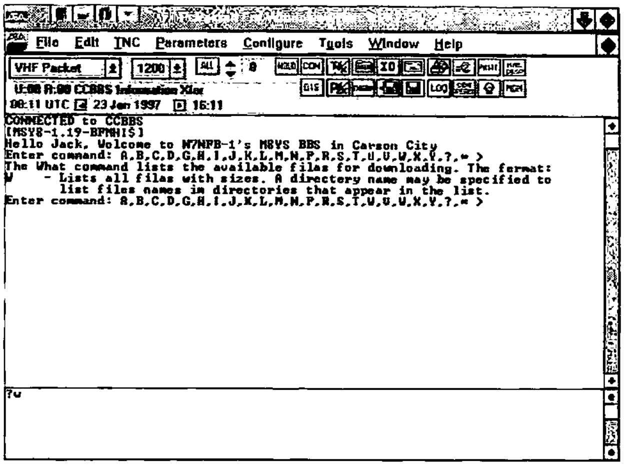

Photo B. Opening screen for BBS. The first four lines appeared, then I entered the "?w", pressed Enter, and it displayed information about the "W" command. Then it redisplayed the command line and is now waiting for the next command.

or when this happens to you, you'll find a lot of hams on the other end of the keyboard who are very reassuring, so don't be afraid to try something new.

Can we *talk?*

If you have questions or comments about this column, E-mail me at [jheller@sierra.net] and/or at CompuServe 72130,1352. I will be glad to share what I know or find a resource for you. On packet, when you get a chance, drop me a line at: [KB7NO@N7NPB.#NONEV.NV.USA.NOAM]. For now, 73, Jack KB7NO.

Space Covers: History In Your Hands

Several years ago, Lynn A. Breece K4LFV, Lt. Col. USAF (Ret.), contacted me after reading several articles about my work with young people in ham radio and about my involvement with the space program.

Lynn began sending unusual and beautiful wall posters of the space shuttles to our classroom. One day, something really special arrived in the mail for the children. Our friend had meticulously collected and assembled two space cover albums for us. Space covers are special commemorative envelopes from the US Postal Service with the mission patch or insignia on them, that are canceled at the launch site. The two albums Lynn sent us contained space covers and memorabilia from STS-30 and STS-34. The children in my 6th, 7th, and 8th grade radio classes were delighted with the albums, which contained the canceled envelopes, newspaper clippings, and a collection of reports about the missions.

A letter writing exchange soon began between Lynn and my classes. The children eagerly looked forward to the many albums and kind letters he took the time to send to us. In October, 1991, Lynn wrote us a beautiful letter describing how he got started in the fascinating hobby of collecting space covers. The children and I agreed that Lynn Breece was one of the most interesting hams we had ever met.

In 1961 Lynn started working at Cape Canaveral and the Kennedy Space Center. At that time, the post office closest to the Cape was in Port Canaveral, Florida. For this reason, you can find covers canceled at Port Canaveral for the launch of Alan Shepard in the first Mercury capsule.

As the Mercury launches proceeded and the Gemini Program got underway in 1965, cancels began to come from the cities of Cape Canaveral, Cocoa Beach, Satellite Beach, and a few other towns which were close to the Cape.

In 1965, the post office at the Kennedy Space Center was opened so that all the NASA launches could then have a cancel from the Kennedy Space Center in Florida. It was standard practice for the post office to cancel covers on launch day as long as the covers were mailed before the set day or were hand-carried into the post office the day of the launch.

Lynn told us that in all the years he's been collecting covers, he has found postal employees to be very cooperative in supplying the proper cancels on the right date. He particularly praised Mr. Al Moore and his staff at the KSC post office for supplying superior service to collectors.

As the space program grew, more and more cover collectors appeared on the scene, including the strictly philatelic ones (collectors of postage stamps). This meant more cachets, different types of covers, and cancels from all sorts of places, such as a town where a particular astronaut was born.

Lynn chose to specialize in getting astronaut signatures on covers; but he also includes NASA officials, scientists involved in the program, cap coms, test directors, launch directors, etc.

The astronauts and others involved in the space program were always very happy to sign covers for Lynn. He wrote the children: "As someone who has lived most of my life in this century, I believe I have seen more history-making events than those living in previous centuries.

"When one considers the space program alone, think of what we have witnessed just in the last 36 years," Lynn points out. "Man's landing on the moon will go down in history as the single greatest scientific accomplishment of the century."

Lynn often followed up our letter exchanges with radio contacts to our classroom. He always felt that young people were the life blood of any organization or hobby. Without youngsters and the enthusiasm and energy they offer, a club or organization would eventually die out. These were always the things he and I would talk about through the three years we knew each other. Lynn was very interested in motivating young people to get involved in ham radio and in the space program.

He always encouraged the children to get involved by collecting space covers, attending launches, visiting NASA centers, reading about space, and talking to hams on the radio with mutual interests.

A ham since 1932, Lynn loved the idea of teaching ham radio to young adults, and continued to be supportive of my program until his death three years ago. His expressed admiration for the children who studied the theory and rules, and who practiced the code and got their licenses, was surpassed only by the warmth and respect my kids felt for Lynn. Through my radio classes, Lynn found an outlet through which he shared his enthusiasm and interest in space and ham radio.

Lynn always hoped that children would look at the past space covers and remember the events they mark. "To own a cover which was canceled on Moon Landing Day or on *Voyager*'s closest encounter with any of the planets is to hold a piece of history in your hands. It is a record of a great event, and one that will stand through the years." Lynn affirmed.

There is a permanent tribute to this wonderful ham friend in my classroom at Intermediate School 72 in Staten Island, New York. All the beautiful space cover albums Lynn sent us through the years are on display for students to keep enjoying and learning from. His love for space and radio will long be remembered and passed along to a whole new generation.

More on ham software

Well, it seems that my complaints about ham software seem to have hit a resonant chord. I received a large amount of E-mail and snail mail from people with one complaint after another. The suspect software covered everything from antenna analysis to terminal node controllers to information databases. It seems that almost all forms of software were involved.

The most frequent complaint was on MS-DOS non-Windows© software. We are seven years into the Windows era, so there is no excuse for offering MS-DOS software any longer. Also, Windows software writing used to be a big deal, but now Visual Basic© and Visual C© are on the market and make the "...contriving of contrivances a game for all..." Visual Basic 5.0 should be out by now. It is said by beta testers to run as much as 20 times faster than VB4, and now competes with Visual C speedwise.

Some guidelines

I would like to offer some guidelines for developers of ham software. I would also like to hear from experienced software developers who have other ideas. Keep in mind that I am not sounding off from any "high horse," because I readily admit that I've made all the mistakes I've complained about in others. But I also bought some books on human computer interface design (see list below) and learned a bit of stuff.

The three pillars of design are usability, functionality and aesthetics:

• Usability means that users can easily learn to use the interface (screen) and then efficiently interact with it.

• Functionality refers the functions and controls that are available on the screen, and their optimal use.

• Aesthetics refers to the appearance, spatial layout, and color scheme. Ask whether or not it enhances or takes away usability and functionality.

Another attribute of a good program is consistency. It is very important to design the program so that the system always interprets user actions the same way from event to event. It should also respond the same way to different instances of the same event. If you make a change from expected behavior, or design an interface that does not match the Windows standard, then make it a large and obvious change so that users know it is not a standard presentation.

"There is no excuse for offering MS-DOS software any longer."

Color is one of the most frequent icky things about computer interface design, and leads to what one authority called "color pollution." Some people seem to think that the more color the better. Or that sexy-looking colors are neat to use.

Color should be used to make things stand out, especially at the specific times when needed. If there are too many colors on a screen ("color pollution"), then the user has a difficult time finding things. Normally, dim or dark colors (deep blue, Microsoft gray, etc.) are better for screens than most light colors. Also, solid colors generally work better than the pastel shades, especially where the standard 8-point type is used on labels placed on the screen.

Color differences can be quite useful when you segment a screen. You can use colors to divide a screen into separate tasks or classes of information. Also, it has been found that color works better for experienced users than for "newbies." If the principal audience is people with little computer experience, then stifle the color.

Long load times are often required for programs. Unfortunately, a long load keeps blank stuff on the screen and that makes users nervous. The user will then start hitting keys or clicking the mouse inappropriately and make the program do odd things. About ten seconds' load time is considered excessive by most users. There are several things that can be done about it:

• First, a splash screen can be provided. This is a screen, usually without borders, that appears as soon as the program loads. It remains on until the entire program is loaded. It typically does not have graphics or any controls because these take too long for loading. In some cases, a 200-mS (or so) timer control (as in Visual Basic) may be used to load the rest of the program from the splash screen Load Event.

• Another trick that can be used is to provide a progress bar. That's one of those green or blue bar graphs that show the percentage of completion. Alternatively, an on-screen message could be provided.

Some questions that you should ask include:

• Does a desired feature have a performance effect? If not, then dump it unless there is a good reason to keep it.

• Is the feature likely to confuse the user? If it does, dump it or redesign it.

• Are any of the controls, functions, or features non-value-adding? If so, then dump them.

• Can controls be combined or eliminated? If so, do so.

• Is the interface as intuitive as possible to the user? If not, redesign it. For the most part, this means that the program should follow the Windows standard format because that is what the user will understand.

Testing

Testing is a necessary although often not sufficient means for telling how well the program works and ferreting out bugs. Unfortunately, most ham software seems to be tested by the programmer, rather than by a typical user. Programmers make lousy testers because they are usually too close to the program. They can easily overlook obvious problems because they have little mental workarounds. They know how the program is supposed to work, so they may overlook some obvious errors that typical users might make. They are also confident using computers, where real users might be frightened of the machine. The goal is to make the user population as representative of the customer population as possible, even if it means giving away free beta testing copies.

Observing testers can sometimes be a problem. The tasks they are asked to perform should be realistic and truly representative of the tasks normal users will face. The tasks should also cover the full range of possible situations, although my answer to trying to figure all of them out is, "Good *luck*!" Also, the observer should be as unobtrusive as possible. The presence of the observer should in no way alter the performance of the user. In general, having someone looking over the tester's shoulder will induce more errors than is normal.

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

How about some more good, down-to-earth tips and ideas to make our hobby more enjoyable and perhaps make it run a little more smoothly? And speaking of running, I'm running a little low on ideas, so please don't put off sending your favorites. Just jot down some things that have made ham radio problem-solving easier for you or for one of your friends, and send them to me at the address above. Uncle Wayne's elves will send you a check for $10 each so that you can afford to buy a couple of the books on his "must read" list. He's recommended some very interesting ones... and here are some other interesting tips:

Superman's AA cells

Looking for a super-capacity AA cell? If you use rechargeable AA cells in any of your portable gear, as I do, it might be worthwhile checking out the relatively new line of NIMH (nickel metal hydride) rechargeable cells. The NIMH chemistry automatically increases the mAH (milliampere-hour) capacity of a rechargeable cell by roughly 25%, and the new AA size NIMH cells boast an 1,100 mAH capacity (a 250-mAH increase over even their newer 850-mAH NiCd counterparts). NIMH cells can be charged in the same manner as NiCds, using a one-tenth-capacity constant-current charger (110 mA constant-current for the 1,100 mAH NIMH cells mentioned). The NIMH chemistry has less tendency toward "memory effect" than does the NiCd formula and the cells can withstand more heat. All in all, a worthy competitor to the venerable mainstay of our rechargeable repertoire of cell chemistries. One source of rechargeable NIMH "AA" cells is DC Ace Electronics (847-821-8122), who lists the 850-mAH "AA" NiCds at $2 each and the 1,100-mAH "AA" NIMHs at $2.50. When you compare these prices against the name-brand "use-em-once-&-toss-'em-away" alkaline cells, the choice is pretty clear... especially for battery-operated equipment that's used a lot. Though the better alkaline "AA" cells are rated at 2,450-mAH capacity, 2 or 3 uses from the NIMH cells will quickly put you in the "money-ahead" bracket. **Fig. 1** shows the basic constant-current NIMH 110-mA "safe" charger that I've been using for the "AA" cells in my GPS receiver.–**de Dave NZ9E.**

"When you compare these to the name-brand alkalines, the choice is pretty clear... "

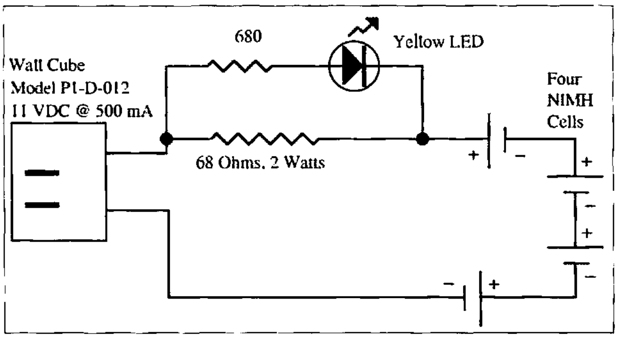

Fig. 1. A constant-current (110-mA) nickel metal hydride charger circuit suitable for charging four NIMH cells in series. The value of the 68-ohm resistor may need to be adjusted to achieve 110 mA, depending upon the characteristics of the transformer that's used. See text for further details.

CBer's PL

From Gary Holoubek WB6GCT: "Ever heard of 'CBer's PL'? That's the name I've given to the alternator whine that can be heard on all too many of even the best of ham radio mobile installations, and nearly all CB mobile signals! I thought I knew all about such problems until I installed a bank of radios into a friend's 1990 Lumina. My friend and I both enjoy having 3-band capability (146, 220, 440 MHz) in our mobiles, and it took me several days to design and build the hardware to stack the equipment between the vehicle's floor and dashboard in a neat vertical rack array. Today's small cars can often be a real challenge! Everything worked fine... that is, until I did some customization... and that's when Murphy struck!

"Knowing that microphones sometimes never make it back to their correct hangers, and with use, could become a confusing tangle of microphones and coil-cables, I decided to use only one microphone for all three radios and switch it to the desired transceiver with a rotary selector switch mounted in a mini-box. The three transceivers are all Yaesu, and fortunately, they use the same type of microphone and pinout connections. Sounds simple enough!

"The microphones are of the 8-wire type, with signals for microphone audio, up/down frequency control, speaker audio, +5 volts for powering the Touchtone® circuit in the microphone, and of course a common ground for everything. With a little bit of imagination, I thought of all the different things I could possibly do to make this a really whiz-bang installation. Realizing that the radios would be used at night and the position of the transmitter selector switch knob would not be easily visible, I decided to use the +5 volts in the mike cable to power three LEDs... which would indicate which transmitter the microphone was delegated to. I even used a different colored LED on the switchbox for each of the three transmitters. This would allow the operator/driver to determine which transmitter was 'ready-to-go' at a glance. It worked great! Even the speaker outputs from each radio were run through the switching box and an output jack made available to drive either an external speaker or a headphone for 'silent running'... all automatically switched with the microphone. Hey, no telling what an engineer can do with a little time and imagination!

"When all was said and done, I ran into an interesting problem, something I'd not anticipated. At times, when switching the microphone via the switchbox, the transceivers would key into transmit briefly. I theorized that the problem stemmed from the fact that the Touchtone keying circuit in the mike—which was powered by the transceiver's +5 volts—would create a spike on the +5 volt line as the switch was rotated and the power to the mike's TT circuit was pulsed on and off (I was using a break-before-make rotary switch). After installing three diodes, so that the microphone could draw power from all three radios but without allowing the +5 volts from one radio get into another, the problem disappeared. One of those 'little things' that doesn't show up until you actually put an idea into practice!

"Now everything was working fine until my friend actually drove the car! Yep, you guessed it. 'CBer's PL.' But I couldn't see how the alternator whine was getting into the transceiver's audio. I had brought the power for the transceivers directly from the battery and had even used a 30-amp relay to switch the rigs on and off with the ignition key... same as the regular car AM/FM radio. This allowed my friend to keep the audio volume controls in the same position and ensured that all of the rigs were OFF when leaving the car, and ON whenever the ignition was ON. I even installed a switch on the radio console to select either the ignition switch or direct battery power to enable the relay. That way the radio stack could be powered up without the

ignition key for those times when operating mobile at a fixed position (as might be done during extended public service duty) was called for.

"In trying to figure out just what was causing the 'CBer's PL' problem, I did what every budding engineer (?) does when he has a problem. I talked it over with anyone who would listen! Following the suggestion of another technically-oriented ham-friend, I disconnected the two unused mike cables that run between the switchbox and the transceivers, leaving only the active one in use. No help. Of course, the alternator whine was gone with the microphone connected directly to the transceiver, bypassing the switchbox entirely...but the switchbox was such a neat idea!

"So one weekend, armed with a portable scanner receiver set to the transmitting frequency in hand, I decided to get to the bottom of the problem. First, I found that removing the metal box from the radio stacking bracket (i.e., simply ungrounding it from the vehicle's frame) eliminated most of the noise. Interesting! Now, disconnecting the unused radios removed all the rest of the annoying whine. Even more interesting! It turns out that what I had done was to connect all of the grounds together inside the switchbox and then ground them to the metal switchbox itself, so that everything would be shielded from any source of noise. So much for that great idea! Instead, I now disconnected all the grounds from each other and from the box ground, and routed them through the rotary switch instead (fortunately, I had an extra set of contacts to do it). Now, none of the microphone cable grounds were connected to the switchbox or to each other any longer... and that turned out to be the final cure.

"Everything was working fine until my friend actually drove the car."

"Here's what was happening: As we all learned in basic electricity, electrons will take any and all paths available to them to get to wherever they are going. Now since the alternator is mounted on the engine, and thus grounded to the engine, and the vehicle's negative battery terminal is also grounded to the engine via a nice thick cable, a classical ground loop was set to exhibit itself. And it waited there patiently just for me to come along!

"The bulk of the alternator's ground current will travel via the heavy cable to the battery. But what I had done by grounding the switchbox to the radio stack bracket was to provide another path for the electrons to get to the battery via the car frame ground in the switchbox; then to the transceivers via the microphone cables; and finally to the battery via the transceivers' power wiring. Admittedly, the actual current through the microphone cable was probably small, but not all that much is needed since the microphone is a low-level circuit whose audio is greatly amplified... along with any noise in the form of alternator whine. End of mystery!

"If you would like more exact details on how I connected everything up, or on where I found the parts to do it, etc., just send me an SASE (self-addressed, stamped envelope). I'll tell you all about it—perhaps more than you care to hear! I hope these tips and experiences prove helpful at some time to other *73* readers."

Moderator's note: Interesting story, Gary—thanks for sharing it with us. Gary's experiences are a good lesson for all of us to keep in mind. It pays to watch for those sneaky multiple ground paths, especially where very low-level audio circuits are concerned. It also illustrates how every problem (hopefully) has a solution waiting to be found in a regimen of logical thinking and practical troubleshooting approaches. Sleeping on it often helps, too!

Cleaning pots...but not pans

From Richard Measures AG6K: "Noisy or intermittent front-panel control potentiometers

on today's ham transceivers can sometimes make operation frustrating instead of the joy it should be. The reason for the intermittent pots can often be traced to the grease originally used to lubricate them becoming sticky and gummy with age and the effects of oxidation. This in turn causes the contact between the rotating wiper-arm and the resistance-film to suffer, making poor or even no contact at times.

"One cure is to stand the set up on its back, using thick padding or the original packing foam as a protective cushion, and then carefully remove the knobs from the offending controls. Using a syringe with a small-gauge needle, inject TCE degreaser down into the clearance spaces next to the concentric shafts of the pot or pots you wish to clean. Once the degreaser has penetrated, rotate the shafts back and forth a number of times to work the cleaner in and to loosen the gummy grease. When the pot has been thoroughly 'exercised,' inject a bit of GC Electronics deoxidizing cleaner or one of the other newer products that are now on the market. The GC Electronics material can be thinned with about 50% TCE to help it penetrate down into the tiny clearance areas between the pot's shafts if necessary. Caution: TCE is considered to be carcinogenic and should be used only in a well ventilated area, with tools and hands thoroughly cleaned afterward. Wearing disposable latex gloves will help to protect you even more effectively by preventing absorption into the pores of your hands.

"Once you've completed the procedure, turn the set back on and check for any further intermittent action in the cleaned pots, repeating the operation if needed. This is a good deal quicker and less costly than replacing the potentiometers, and should keep them working properly for a number of years to come."

Moderator's note: Pots on equipment used in a mobile environment may need this treatment even more frequently due to the rigors of heat, cold, and dust that are often present in a mobile installation. In fact, even fairly new rigs will exhibit very "stiff" control action when the winter temperatures drop below zero in the northern areas of the country, often requiring this "de-gumming" sooner than home-based equipment. Radio Shack™ now sells several cleaning chemicals that can also be tried—some are "plastic-safe" as well as EPA-approved. Another brand worth looking at is made by Caig Laboratories of San Diego CA (800-224-4123 or 619-451-1799). It goes under their brand name of DeoxIT™. DeoxIT is a deoxidizing solution that cleans, preserves, lubricates and improves conductivity, all in one treatment. Using the procedure outlined by Rich, however, will pretty well assure you of getting the cleaner into the right spot—not everywhere else that you don't want it to be!

Good labels

From Phil Salas AD5X: "For labeling front panels on my homebrew projects, I create a full-size front-panel sheet on my computer with all the labeling neatly done, and then I print it out on a laser printer. I make the sheet slightly smaller than the front panel itself, then cover it with clear shelf paper lining... with enough overlap to hold it to the front panel. This clear shelf paper lining is very inexpensive. You can buy a large roll of it at most grocery stores, in the kitchen sundries section, for about $3 or so. The switches, indicators, connectors, and so forth on the front panel itself will contribute to holding the sheet firmly in place. You could also apply some type of glue to the back of the paper, although I've not really found that to be necessary."

Moderator's note: 3M™ also makes a Scotch™ brand double-stick tape that may work in conjunction with Phil's suggestion: their No. 66 series tape, available in most office supply stores. It's a clear-film type that's adhesive on both sides, and small strips of it can be placed on the back of the areas where a wide expanse might otherwise result in buckling. I've also used the clear, self-adhesive covering made by Contact™ as a protective film for panel labels and other paper surfaces that I've wanted to preserve from wear and tear. It can be found in most hardware and variety stores.

Color me DEKA

From George Primavera WA2RCB: A tip for changing the hue of incandescent lamps used in radio LCD edge-lit displays, meters, dials, and many other places: "My Kenwood TM-241A 2-meter rig came with the standard edge-lit LCD display. The first thing I noticed was that the white incandescent edge-lit LCD was a bit distracting in the car at night, even with the dial dimmer turned down to the low back-light setting. What it needed was a coloration on the edge-lighting bulbs that was more night-vision friendly! A trip to our local art supply store netted a variety of colored (but still transparent) glass paint bottles under the 'DEKA' brand name (made by Decart USA, Inc., Lamoille Industrial Park, Box 309, Morrisville, VT 05661). DEKA is a color base 'paint' used by artists to paint pictures on glass, but I found that the 'paint' could also be useful for adding a nice color-tint to the miniature incandescent lamps used in my 2-meter rig.

"The procedure itself is very easy. First remove the bulb(s) that you want to color-tint, then grip them by their wire leads, using an alligator clip. With the leads pointing up, dip the bulb directly into the bottle of glass 'paint,' taking care to not get any paint on the wire leads themselves... the bulb should be dipped into the paint up to about 3/4 of its length.

"Now touch the tip of the bulb to a clean piece of metal once or twice to remove any excess paint from the bulb's tip-end, then wedge the alligator clip holding the bulb under some heavy object (miniature organizer drawers work well) to hold it in place. The bulb should be suspended in 'midair' and allowed to dry overnight (generally eight hours is the minimum drying time, depending upon temperature and humidity). Next, simply reinstall the bulb back into the radio from whence it came, reassemble everything, and turn it on. My TM-241A now sports a nice pumpkin-orange tint on its LCD, thanks to the newly colored backlight. It's noticeably less distracting while driving at night in a mostly darkened passenger compartment.

"A few precautions on this procedure should be mentioned: *Do not* color-tint any lamp larger in size than three watts, nor one that normally gets warmer than you would be able to touch safely while in operation. I've had no problems with the grain-of-wheat bulbs used in radios, or with #47 pilot lamps used as panel indicators, but automotive-type lamps (such as 1157) get much too hot. The paint will flake off from the excess heat in just a short time. Also, *never* apply this treatment to *any* kind of halogen lamp. Halogen bulbs must be meticulously free of any foreign substances on their glass or they can shatter violently! The colors that I've found to work best are #30—Light Blue, #27—Orange, #26—Lemon and #28—Light Red. Note that lamps treated with the #30—Light Blue color will have a reduction of about 60% in their visible light output.

"I'd recommend using this procedure on glass bulbs only if you try it on a 'throw-away' first. Plastic-encapsulated light devices, such as LEDs, might be chemically attacked by the solvent base of the glass paint."

Recycled tubing

From Bob Boehm N8EXF: "The plastic tubing used in hospitals and nursing homes can often have applicability to our hobby! The rippled hose used for oxygen transfer to a patient can often be salvaged for use as a plastic conduit for running cables in your ham shack or perhaps in a mobile installation. The hosing can be used as is, or slit with a sharp knife along its length so that wires and cables can be tucked into it and given additional protection in harsh environments. Or maybe you can just keep those wires and cables a little neater-looking for appearance's sake...

"Likewise, the smaller-diameter plastic tubing used for intravenous feeding, etc., makes great insulated, protective tubing for a number of ham and electronic applications. I use a length of it over my HF mobile whip antenna to act as a cushion between the whipping antenna radiator and the painted body of my van. The thick plastic tubing keeps the bouncing whip from marring the paint job on the back of my van very nicely. Generally, these hospital throw-aways are made of good-quality plastic material and should last for a number of years of exposure to the extremes of weather and friction. Give it a try."

Moderator's note: I like Bob's idea. I saved some of the small tubing from my own hospital stay a number of years ago and have used it in numerous

"Halogen bulbs must be clean, or they will shatter violently!"

applications since that time. The lengths are usually long enough to protect a vertically rising antenna wire from direct contact by the inquisitive fingers of neighborhood children (or paws of pets), and you surely can't beat the price! [That may be subject to debate.—Ed.]

Murphy's Corollary: Everyone has a foolproof scheme. It's easy to spot... it's usually the one that isn't working!

Communications Simplified, Part 17

Peter A. Stark K2OAW
P.O. Box 209
Mt. Kisco NY 10549

Optical Fibers

As fiber optic cables fall in price, they are being used more and more for communications. In a nutshell, electrical signals are converted into a light beam (possibly visible, but more likely infrared) with an LED (light-emitting diode) or laser; the light beam is sent through a fiber made of glass or plastic; and then it's converted back into an electrical signal with a photodiode or phototransistor. Thus the fiber cable simply replaces the copper wire.

The optical fiber, however, has a number of features that make it superior for some applications. For one, its attenuation is much, much lower than that of cable, especially at high bandwidths. It is entirely practical to send high-speed data or analog signals some 30 to 40 miles without needing to amplify or regenerate signals along the way.

Optical fibers also offer immunity to electrical interference. They do not leak energy outward, are extremely difficult to tap, and do not accept interference from other nearby signals. They are also immune to nearby lightning strikes, although this is sometimes compromised by cables that contain both optical fibers as well as electrical conductors inside the same cable.

Fiber optic cables can be made of either glass or plastic. A typical cable generally looks like **Fig. 1**, and consists of three parts:

a. The core is at the center. Made of very pure, clear glass or plastic, the core passes the light beam from one end of the fiber to the other.

b. The cladding is a second layer of glass or plastic, wrapped around the core. This layer is made of a slightly different glass or plastic, one that lets light travel just a bit faster than the core.

c. The jacket covers the outside of the fiber and protects it. In some fibers, additional jacket layers, including perhaps even metal sheathing, may provide additional protection.

To understand how this works, imagine that we are laying out an automobile race course. In order to keep cars from straying off course, we construct it as shown in **Fig. 2**. In the middle is the race course itself, constructed of a very smooth surface designed for minimum friction. This is where we want each car to drive.

On each side of the racing lane we put a second lane made of a slightly different material, one which provides slightly better traction. This is labeled the speedup lane in the figure. Finally, at the very edge, just in case a car gets too far off course, we'll put a layer of sand to stop it so it can't wander back into the course and get in someone else's way.

So now look at car 1, which has somehow gotten slightly off course. As soon as it enters the speedup lane, the left wheels will have slightly better traction than the right wheels, so its left side will wind up traveling just a bit faster. This is going to turn it slightly to the right, so it goes back onto the racing lane. Car 2, on the other hand, is so far off course that it too will turn a bit to its right, but not

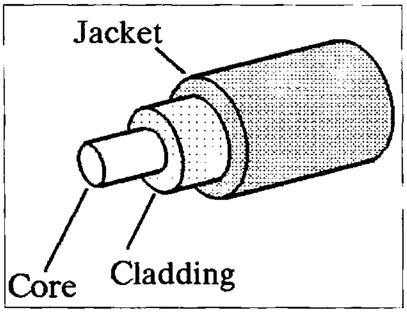

Fig. 1. Optical fiber construction.

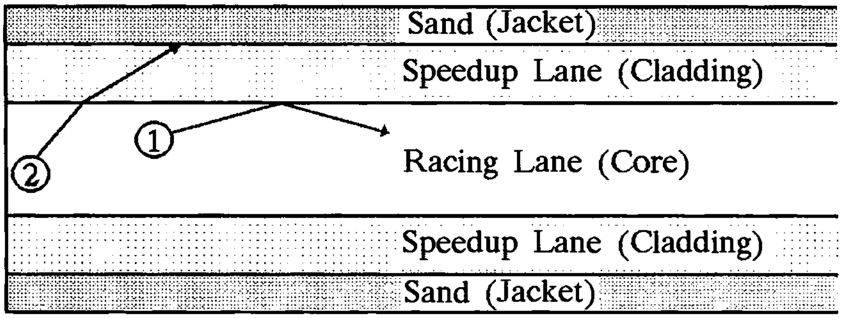

Fig. 2. Keeping a ray on track.

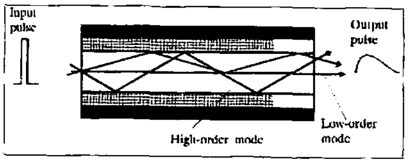

Fig. 3. Multi-mode fiber.

enough to return to the course. It will eventually get stuck in the sand, and that will keep it out of trouble.

Thus the speedup lane keeps the cars from straying off course, without any intervention on their part. You could almost put a blindfolded driver into a car, and the course itself would keep him on track.

The optical fiber works exactly the same way. The cladding is made from a glass that lets light travel just a bit faster than the core. In terms of physics, the core has a slightly higher index of refraction than the cladding; this makes light travel slightly more slowly in the core than in the cladding. When a ray of light tries to leave the core and enter the cladding, it is bent back just enough to reenter the core. If it's like car 1, it returns to the core and keeps going. But if it's like car 2, then it goes right through the cladding until it hits the jacket, and gets stopped.

It is important to realize that the process of "bouncing" off the cladding back into the core is not the same as reflection off a mirror. Reflection in a mirror always loses a small amount, since no mirror is perfect. Refraction, as it is called, is 100% efficient—there is no light lost in the process. The only light that is lost is due to any impurities in the glass.

Fiber optic cables can actually be made from either glass or plastic. As such, they come in three types:

•All glass is best, and most expensive.

•All plastic is worst, but cheapest.

•Plastic-clad silica (PCS) is a compromise, where the core is quartz-like form of glass called silica, but the cladding is plastic.

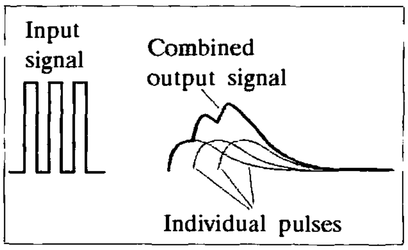

Fig. 4. Dispersion spreads pulses.

The difference is primarily due to the fact that glass is clearer, and therefore significantly more light gets through the fiber. Because of the loss of light, plastic fibers are only usable in short lengths of a few hundred feet, whereas glass fibers can be dozens of miles long.

Transmission modes

Referring to **Fig. 2**, we can see that a car which goes straight down the core will make better time than a car which constantly bounces from edge to edge. This is an extremely important concept in optical fibers as well, because it determines the dispersion of light.

Fig. 3 shows a stepped-index or multi-mode fiber. It is called stepped-index because there is a sudden change (mathematicians call it a step) in the index between the core and the cladding; it is called multi-mode because it permits many modes. The mode describes the path that a light beam takes: a low-order mode is one that goes directly through, taking as few bounces as possible. A high-order mode is one that takes many bounces before arriving at the far end. Obviously, a high-order mode light ray must travel a greater distance to the far end, and so arrives later than a low-order light ray. If the light is pulsed on and off, as shown at the left, the pulse arrives at the far end spread out, as shown at the right. The term dispersion describes how spread out the pulse is at the output.

The amount of dispersion depends on the length of the fiber. When a fiber is short, the difference between a low-order path and a high-order path is fairly small, so the total dispersion is fairly small as well. The longer the fiber, the greater the difference in path length, and therefore the greater the dispersion.

Fig. 4 shows why dispersion is a problem. Most fiber optic cables are used for digital signals; the bandwidth of such a cable depends on how many pulses can be sent per second. When a fast series of such pulses is sent through the cable, dispersion spreads out each pulse as shown. The pulses then overlap, making it harder to properly separate and detect them. When dispersion makes adjacent pulses blend together too much, the only solution is to separate the pulses farther apart. This limits the number of pulses that can be sent per second. In other words, the bandwidth of the fiber depends on its dispersion, which in turn depends on its length—the greater the length, the lower the bandwidth.

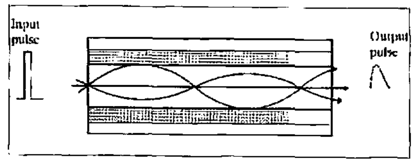

Fig. 5. Graded-index fiber.

A graded-index fiber **(Fig. 5)** is a partial solution to the problem. Rather than having a sudden change in the index of refraction between the core and the cladding, the graded-index fiber has a gradual change in the index. This has two effects. First, it results in the light rays gradually bending back toward the middle, rather than abruptly "bouncing" back and forth. This tends to gradually straighten out the light path, causing more of the rays to travel along low-order modes rather than high-order paths. A more important effect is caused by the fact that the index of refraction is highest in the middle of the fiber, and gradually decreases as you go outward. Light rays traveling toward the edges of the fiber therefore move faster than those in the middle. Even though they travel a longer distance, the faster speed lets them catch up with the lower mode rays in the center. The result is less dispersion.

The best solution to the dispersion problem is with a single-mode fiber; a fiber which has only a single possible mode of light transmission. Just as two out-of-phase electrical signals can cancel, so two out-of-phase light rays can cancel. Because of this interference effect, there are only certain specific light paths (modes) in a fiber which are possible; all others cancel out because of interference. If the core is made thin enough, the only mode that is possible is the one straight-through mode in the middle. The resulting single-mode fiber, shown in **Fig. 6**, thus has much less dispersion and therefore a higher bandwidth.

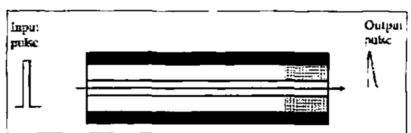

Fig. 6. Single-mode fiber.

You can understand, though, that a very thin single-mode fiber will let through much less light than a thicker multi-mode or graded-index fiber. For that reason, single-mode fiber generally requires a glass core which, because of its clarity, attenuates the light less. Plastic fibers, on the other hand, are usually thicker to let through more light. This increases dispersion and thus reduces their bandwidth, but this is not much of a problem because their attenuation is so high that they can only be used in shorter lengths; at these lengths, dispersion is not as bad as it would be in *very* long lengths.

Fiber characteristics

Let us next look at some characteristics of actual fibers of various kinds, listed in **Table 1**.

Core and cladding diameter

Fiber diameters are given in µm or micrometers—10^{-6} meters. To put this into context, note that a typical human hair is about 50 µm thick, so the thinnest fibers are about 1/10 of the thickness of a hair. Fiber dimensions are usually stated as two numbers separated by a slash; that is, a 50/125 fiber has a 50-µm core diameter and a 125-µm cladding diameter.

In general, the plastic fibers are much thicker than the glass fibers, although multi-mode glass fibers can also be quite thick. The thinner fibers obviously must be much clearer to let through enough light.

Attenuation

The attenuation determines how long a cable can be used before the signal becomes too small to be useful. It is rated in dB of signal loss per kilometer of length. The best glass fibers have losses below 0.5 dB per kilometer, whereas some of the plastic fibers have losses of as much as 400 dB per km.

The best glass fibers are amazingly clear—a 6-km length of glass single-mode fiber, about 4 miles, would have a loss of about 3 dB. To realize just how amazing this is, think of a piece of window glass 4 miles thick. With ordinary glass, you probably would not even be able to detect light through it. With a fiber, a 3-dB loss means that half of the light entering it comes out the far side!

Even with 30-mile lengths (about 50 km) of a good glass fiber, the loss is only some 20 or so dB—a loss of 99% of the light power, but still within a reasonable range. Plastic fibers, on the other hand, can have huge losses. At 400 dB per km, 20-dB loss would occur in about 1/20 km, or about 150 feet. Because of this high loss, the maximum usable length of a plastic fiber is a few hundred feet—long enough to go within a small building, but not much more.

Type	Core Diameter (µm)	Cladding Diameter (µm)	Attenuation (dB/km)	BW MHz•km	NA
Single mode glass	5	125	0.5	1000+	small
	8	125	0.4	1000+	small
Graded index glass	50	125	4	400	.20
	63	125	7	250	.29
	85	125	6	200	.26
	100	140	5	20	.30
Multimode glass	200	380	6	25	.27
	300	440	6	20	.27
Multimode PCS	200	550	10	15	.30
	800	900	6	20	.30
Multimode plastic	980	1000	400	20	.50

Table 1. *Optical fiber characteristics.*

It is interesting to compare fiber attenuation with the attenuation in copper cables. The attenuation of copper cables increases with the frequency of the signal. For example, good quality RG-8 with a foam dielectric has about 1.2 dB loss per 100 feet at 50 MHz, about 2 dB loss at 150 MHz, and 3 dB loss at about 300 MHz.

Let's look only at the loss at 50 MHz, since that is close to the 47.736 MHz data rate of a T3 line, a common data speed in optical fibers. Since there are about 3300 feet in a kilometer, a 1-km length of RG-8 would have about 40-dB loss at 50 MHz. Even one of the best and most expensive coax cables (7/8-inch-diameter hardline) would have a loss of 12 dB per km at 50 MHz. Compare this with the 0.5 dB per kilometer loss of a good glass optical fiber, and you can clearly see the advantages of fibers over long distances.

Attenuation vs. frequency

As we just mentioned, the attenuation in copper cables depends greatly on the frequency, and therefore affects the bandwidth. As the frequency increases, the attenuation goes up very fast, and this greatly limits the bandwidth.

When talking about fiber cables, however, we must be careful, because there are two frequencies to consider—the frequency of the light (which actually describes the light's color), and the frequency of the data (which describes how fast the light is turned on and off in the case of digital data, or how fast its intensity changes in the case of analog data). Rather than use frequency, however, physicists use the wavelength since it is easier to measure (as you remember, the wavelength is the velocity divided by the frequency, so it is easy to convert back and forth). The wavelength is measured in nanometers or nm (one nm is 10^{-9} meters), and the colors measure approximately as follows:

- Ultraviolet: shorter than 400 nm
- Violet: 400-450 nm
- Blue: 450-500 nm
- Green: 500-570 nm
- Yellow: 570-590 nm
- Orange: 590-610 nm
- Red: 610-750 nm

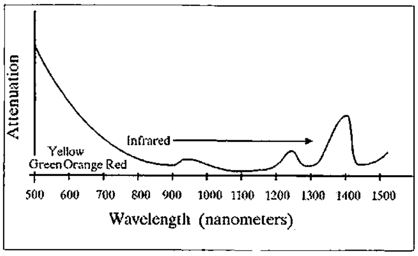

Fig. 7. Attenuation of glass fiber.

•Infrared: from about 750 to about 1400 nm

(Ultraviolet and infrared wavelengths are also considered to be light, but they are invisible to the eye.)

Light's wavelengths are so short that they are greatly affected by molecular and atomic characteristics of materials. For example, **Fig. 7** shows the attenuation of glass at various wavelengths. We see that the attenuation varies quite a bit with wavelength. At very short wavelengths (toward the left of the graph), light transmission is affected by individual atoms—the farther left you go, the greater the attenuation, so these wavelengths are not very useful for optical fibers. At longer wavelengths (toward the right), light transmission is affected by certain combinations of atoms, and so there are specific wavelengths that are highly attenuated, while other nearby wavelengths get through with relative ease. As long as we stay away from these attenuation peaks, the red and infrared wavelengths will work best.

This is fortunate, because LEDs and diode lasers are easier to build, more efficient, and cheaper at infrared and deep red colors. Glass fibers are generally used with infrared light between 790 and 1300 nm because that is where the attenuation is least. Plastic fibers, on the other hand, are usually used with red light at about 650 nm.

Note that it is possible to send several different colors through a fiber cable at the same time, as long as we choose the colors wisely. Thus it is possible to send two or more different signals through the cable. Still, this is not too common in longer cables, because feeding two or more color sources into the same fiber, and then separating them again with colored filters, introduces losses that limit the distance.

The attenuation of various colors is thus a separate topic from the concept of signal bandwidth.

Signal bandwidth

The bandwidth of a fiber is related to how fast we can turn a beam on and off, or more likely, how fast we can change its brightness (because even in digital applications, the beam is usually switched between bright and dim, rather than between bright and off).

This speed is determined by two factors: the speed at which the light sources and detectors can work, and the dispersion in the fiber itself.

As we showed in **Fig. 4,** dispersion makes adjacent pulses blend together; they therefore have to be separated farther apart.

Since the dispersion increases with the length of a fiber, the pulse rate for a given fiber is inversely proportional to the distance. If the length (in km) is large, the frequency at which we can switch the beam (in MHz) is small, and vice versa. The product of these two quantities is therefore fairly constant for a given fiber, and is given in "MHz times km" or MHz•km. This number is listed in the bandwidth column of **Table 1**.

For example, the bandwidth for single-mode glass fiber is shown as 1000+ MHz•km (the + means that it is 1000 or greater). Assuming a value of an even 1000, a 1-km length of fiber would have a bandwidth of 1000 MHz; a 10-km length would work up to 100 MHz; and so on.

Compared with 1000+, the rating of 20 MHz•km for multi-mode plastic fiber looks awful... until we put it into context. Remember that, because of its attenuation, plastic fiber is limited to a small fraction of a kilometer. For instance, consider a plastic fiber 1/20 km long; at that length, the bandwidth is still a respectable 400 MHz (since 400 MHz times 1/20 km is 20 MHz•km). Thus plastic fiber can also be used for high bandwidths, but clearly only for short distances.

This helps to explain why no one bothers to make single-mode plastic fibers—there is simply no way to take advantage of the lower dispersion that this would provide.

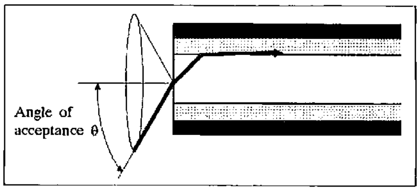

Fig. 8. Numerical aperture with cone of acceptance.

NA or numerical aperture

The last column in **Table 1** shows the numerical aperture for various fibers. The meaning of this measurement is shown in **Fig. 8**.

The dark line at the left in the figure shows a light ray which comes into the fiber at such a steep angle that it hits the cladding and stays there; it does not "bounce" off it back into the core. Clearly such a light ray is not going to make it to the far end. Furthermore, any other light ray that is at that angle or more will not make it through either.

The result is that there is what we call an *angle of acceptance* q, which defines the cone shown in **Fig. 8**. Light coming in within that cone will be transmitted through the cable; light coming outside that cone will not. The light coming out the far end of a fiber will generally come out in a cone of the same angle, though in some cases the higher-order light modes can be attenuated in a longer fiber, with the result that the light comes out in a narrower cone.

The numerical aperture NA is simply the sine of the angle q, namely

numerical aperture NA = sin q

From **Table 1**, we see that the NA is between 0.2 and 0.3 for most of the fibers shown, corresponding to angles q of 12 to 18 degrees. Multi-mode plastic fiber's NA of 0.5 corresponds to 30 degrees, while single-mode glass fiber has acceptance angles of less than 10 degrees.

The NA is important when matching a fiber to the light source or light detector, or when connecting two fibers together. For example, a plain light bulb would be a very bad light source for a fiber, since its light comes from a large area, most of which would be outside the angle of acceptance.

2m Self-Supporting Delta Loop

So simple—and perfect for apartment dwellers.

Thomas M. Hart AD1B
54 Hermaine Ave.
Dedham MA 02026

While sitting on the couch, reading the newspaper, and listening to some local 2m repeaters on my handie-talkie, I decided my signal needed some additional punch. The handie-talkie with three-inch antenna was not producing anything near the desired "dead full quieting" on certain local machines when it was my turn to comment. Buy an amp? Resurrect that 5/8-wavelength whip? Both of these were unalluring prospects for reasons of cost and ergonomics. My thoughts turned to something different.

Photo A shows a full-wave delta loop for 2m that can be deployed when needed or folded up and stored at other times. The loop is self-supporting, fed with 50-ohm coax, and offers an excellent SWR. The woodworking tools required are simple; tune up is easy; and it travels well. The design is for vertical polarization, the norm on 2m FM work.

The materials for the frame include a 12-inch-wide pine board, two 36-inch dowels of 1/2-inch diameter, a bolt with wing nut, and a spring-loaded clothespin. The wire used in the element is Radio Shack™ hookup wire fed by an SO-239 fitting. An appropriate length of coax is used to connect to the rig.

My only test instrument was a Radio Shack 2m SWR meter. The final tune-up assembly eliminates the traditional "cut, cut, cut, oops—too short" method in favor of a nut and bolt slider. When complete and sitting in the middle of the room, the antenna performs remarkably well. Further, it is less expensive and cumbersome than either of the initially considered alternatives.

Construction was easy (see **Fig. 1**). I cut a 12-inch-diameter circle from the pine board and drilled a hole in the center. Careful filing produced a tight fit for the 36-inch dowel that supports the antenna. A second dowel, 28 inches long, was cut for the horizontal element. Then, it was time to rough cut the wire and start final tuneup.

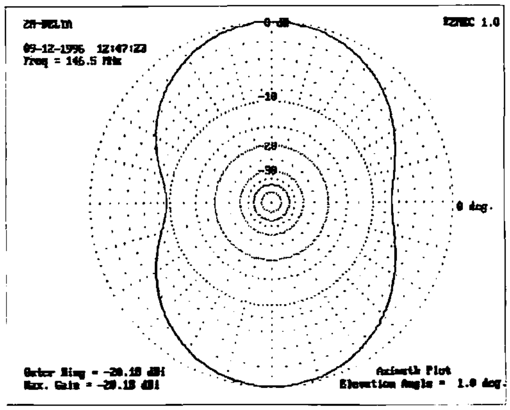

Fig. 2. Software analysis. Azimuth plot of field strength by Eznec software program. Gain is shown perpendicular to plane of loop.

The formula for a loop on high frequency antennas was used as a starting point: Length = 1005/F(MHz) = 1005/146.5 = 6.86 feet of wire.

I cut a seven-foot length of hookup wire and soldered one end to the center connection of the SO-239 connector. A short length of wire with a screw and nut on the end was bolted to the ground side of the socket. This acts as a fine-tuning device.

The loop and frame were then taped together in a rough approximation of the final shape. A period of cutting and SWR measurement brought the loop close to final length. A section of insulation was removed from the end of the loop and final adjustment was made by sliding it through the nut and bolt assembly. When the SWR registered 1:1, I tightened the tuning assembly and used a bolt and wing nut to hold the frame together. Another bolt fastened the SO-239 to the end of the horizontal element, and a spring-loaded clothespin was attached to the vertical dowel to provide strain relief for the coax. The final step was to retune the loop because the SWR changed slightly after the addition of hardware and final shaping.

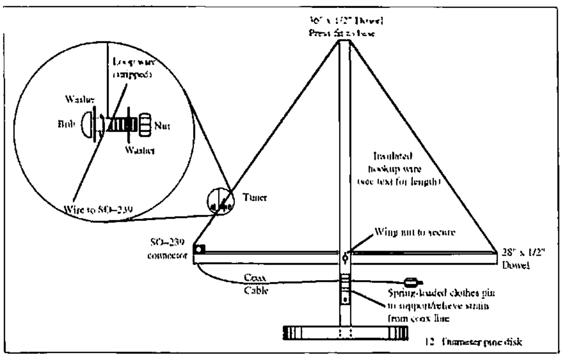

Fig. 1. Construction details.

The loop has worked very nicely for me. I stand it in the middle of the floor and have no trouble working all I can reasonably hear. Recently, it was interesting to pick up a signal from a repeater located on Long Island. By rotating the loop, I was able to bring the signal up to a very reasonable level. I could not work that repeater because the local machine would come on and cover up Long Island. I was impressed by the directivity of a single loop, however. This self-supporting loop has worked very well and is a simple alternative to running higher transmitter power.

Home-Brew Transistor/Diode Tester

Not just blinking lights and weird noises.

Henry L. Bowman
Rt. 1, Box A-190
Parsons TN 38363

Although I'm not a radio amateur, I enjoy reading each new issue of *73 Amateur Radio Today*. Unlike other electronic magazines, which offer construction projects with silly blinking lights and weird noises, *73* provides useful projects that are well worth the time and effort to build. I built J. Frank Brumbaugh's Capacity Meter (March 1996) and have found it to be one of my most useful test sets.

I have always needed a better method to identify and test transistors, but I didn't want to invest a lot of money in commercial test equipment. I decided to build my own tester. The test set described here is designed for out-of-circuit testing, uses two ICs (only 1 if you use the dual 556 timer), and can be built in an afternoon. It will automatically identify transistors for NPN or PNP type

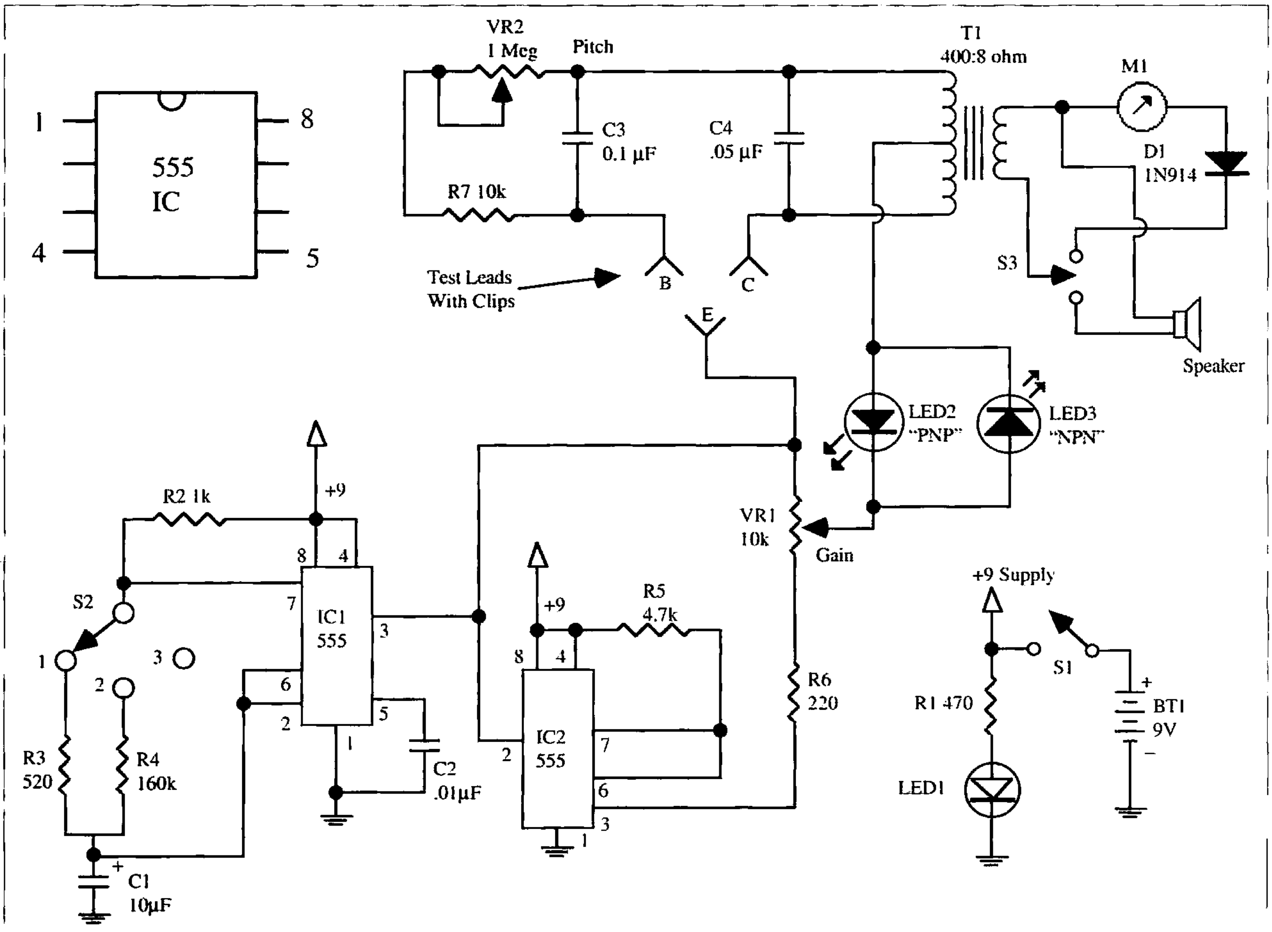

Fig. 1. The transistor/diode test set schematic. S2 positions: (1) diode test; (2) transistor test/identify; (3) freeze last pulse.

as well as give you a relative indication of gain. In audio mode, unmarked transistor leads can be identified. Diodes also can be checked for shorts, opens and polarity.

Circuit description

Fig. 1 provides the schematic diagram of the transistor tester set. IC1 and IC2 are both 555 timers and their outputs are capable of sourcing or sinking up to 150 milliamps of current. IC1 is connected as an astable multivibrator and the output clock rate is dependent upon the values of C1, R2 and the setting of selector switch S2. The output clock from IC1 is connected to the trigger input of IC2 and also connected to one side of variable rheostat VR1. IC2 is wired as an inverter and simply provides a complementary output, of IC1, to the other side of VR1. When the selector switch is in position 1 or 2, the DC voltage on the two 555 timer output pins is continually reversing in polarity and similar to a flip-flop in operation. When the selector switch is moved to position 3, the RC network of IC1 is disconnected so that the last output voltage pulse remains constant.

The wiper arm of VR1 provides an adjustable voltage, in series with LED1 and LED2, to an oscillator circuit, which depends upon the transistor under test for oscillation. If a known good NPN transistor is correctly connected to leads E, B and C and the selector switch is set for position 2, the NPN LED should light for approximately one second, remain off for one second and repeat the cycle. During the pulse period that the LED is lit, the transistor will oscillate as indicated by a tone from the speaker or an output indication on the meter, depending upon the setting of switch S3. If the NPN LED lights on one pulse and the PNP LED lights on the next pulse, then the transistor should be considered faulty. R6 provides current limiting to the LEDs, if a shorted transistor were inserted. VR2 provides tone pitch control and also has an effect on transistor gain.

Circuit construction

I built the circuit on perfboard using two 8-pin wirewrap IC sockets to mount the 555 timers. If a low wattage soldering iron is used, wiring can be soldered directly to the IC pins, eliminating the use of sockets. All resistors, capacitors, transformer T1 and the 9-volt battery were mounted on the perfboard; the remainder of the components were mounted on the faceplate. Parts locations are not critical. For the test set faceplate, I cut out a five- by seven-inch panel from scrap aluminum and drilled out holes for the pots, switches, meter, LEDs and test leads. Four 1/8-inch holes were drilled in the midsection to allow audio from the speaker. The aluminum panel just fit a small metal enclosure I had in my junk box. A plastic cabinet with aluminum faceplate is available from Radio Shack™ and gives any homemade test set a professional look. I used color-coded clip-on test leads for the emitter, base and collector connections. These leads have alligator clips on both ends and are also available from Radio Shack. I cut the clips off at one end and soldered the cut ends to the proper components on the perfboard and faceplate, then installed a rubber grommet in the faceplate hole for the test leads, and then ran all three leads through the same hole. I placed a small nylon cable tie around the test leads on the inner side of the faceplate for strain relief; you may prefer to use a larger faceplate and mount several types of transistor sockets, wired in parallel, to provide test connections.

I salvaged the meter from a discarded stereo amplifier, but any 150-200 microamp meter should work nicely. I have also had good luck with 50 microvolt full-scale meters for audio level use. The 50-microvolt meter is intended to be paralleled with a high-current shunt bar, and telephone companies usually replace these meters when increasing their power distribution capacity. If you know someone who works with telephone switching equipment, they may donate one that was removed from their power boards after an upgrade. If you are unable to locate a 3-position selector switch, you can use an SPDT switch to change the pulse rate, and add an SPST switch in series, between C1 and pins 6 and 2 of IC1, to open the RC network and stop the pulse.

The LED indicators LED2 and LED3 should be capable of 50 milliamps of forward current in case a shorted transistor is connected for testing. If you intend to use LEDs found in your junk box, and are unsure of their current capacity, be sure to use red, instead of yellow or green, because they are usually (but not always) rated for higher current. During normal operation, with a transistor connected for test, the total test set current drain is approximately 30 milliamps.

Testing

After assembly is completed and the test set is connected to a 9-volt battery, place the selector switch in position 2 and turn power switch S1 on. LED1 should light, indicating power has been turned on. Using an analog voltmeter, place the voltmeter leads across the collector and emitter test leads. With the gain potentiometer (VR1) turned fully clockwise (all resistance out), you should see the voltmeter indicate approximately 6 volts for a second, then a polarity reversal during the next second, then the cycle repeated over again. If no voltage is observed, move the voltmeter black lead to ground (negative) and connect the red lead to pin 3 of IC1. If a pulsing voltage is observed, move to pin 3 of IC2 and also check for voltage. Recheck all wiring and replace ICs if necessary. After the problem is located and corrected, return to the collector and emitter test points and recheck for alternating voltage. Change the selector switch S2 to position 3. The voltage should remain constant from the last pulse, and you may have to reverse your meter leads to verify. Change the selector switch S2 to position 1 and verify that collector-emitter voltage drops to approximately 2–3 volts. This is because of the rapid reversals (100 cps) that are occurring; the meter is only providing an average reading.

Operation

Connect a known good NPN- or PNP-type transistor to the three test leads, turn switch S1 to position 2 and turn on the power. The LED indicating the correct transistor type should light for approximately 1-second intervals and the second LED should remain unlit. If switch S3 is in the "audio" position, an audible tone should be heard from the speaker each time the LED lights. To "freeze" the pulse, switch S2 to position 3 just as the LED lights. Adjusting VR2 will change the pitch of the tone and also have an effect on gain. Throw switch S3

Parts List	
IC1, IC2	NE555 IC timer or NTE955M
(2) 8-pin IC socket*	
R1	470Ω 1/2W
R2	1000Ω 1/4W
R3	520Ω 1/4W
R4	160k 1/4W
R5	4.7k 1/4W
R6	220Ω 1/2W
R7	10k 1/4W
VR1	10k variable rheostat linear taper
VR2	1 megohm variable rheostat linear taper
S1	SPST toggle switch
S2	3-position rotary switch
S3	SPDT toggle switch
C1	10μF 16V electrolytic
C2	.01μF disc ceramic
C3	0.1μF disc ceramic
C4	.05μF disc ceramic
T1	Audio transformer 400VCT: 8Ω*
M1	Meter 150-200μA
8Ω mini-type speaker	
LED 1, 2, 3	NTE3007 or equivalent
D1	Diode 1N914
(3) Test leads w/alligator clips	
BT1	9V batttery
Snap-on connector for battery	
Case*	
Perfboard*	
(3) Pointer-type knobs	
* Available at Radio Shack®	

from audio to meter. The meter should indicate an output level when the LED lights. If the meter that you used pegs out with every transistor tested, you may have to install a 50k potentiometer in series with the meter to adjust sensitivity. It would be a good idea to check both NPN- and PNP-type transistors before continuing. To check a diode, simply connect the emitter and collector test leads to the diode and switch S2 to position 1. A good diode will light only 1 LED, while a shorted one will light both. Neither LED will light if the diode is open.

Going further

Experimenting with different types of transistors will quickly get you familiar with the test set. You can rapidly sort transistors for types and discard defective ones found in your junk box. You will be able to identify leads on unmarked transistors because the transistor will only oscillate when properly connected. I noticed that some horizontal output power transistors caused both LEDs to light during testing, even though they would oscillate and provide a good output on the meter. After checking the specifications for these transistors, I found that they were manufactured with an internal damping diode which made the transistor appear to be shorted!

You might want to consider adding a milliammeter in series with the collector test lead to measure the current of the transistor under test. To maintain the correct current polarity to the meter will require installing a bridge rectifier circuit in series with the collector and inserting the milliammeter in the center of the bridge. The bridge diodes will route the current in the same direction through the meter regardless of whether an NPN or PNP transistor is being tested. The diode bridge will cause an additional voltage drop of approximately 1.4 volts and this will affect the gain of the test set. In order to compensate for this, you may want to increase the power supply voltage to 12 volts. The 555 timers can safely handle the voltage increase. Do not use a 12-volt supply unless you intend to add resistance of some type in the collector-emitter test circuitry to compensate. The higher voltage can cause the transistor, under test, to break down with reversed voltage (avalanche current) and both LEDs will light providing a false indication that the transistor is shorted.

Another alternative, to measure current, is to add a 100-ohm resistor in series with the collector lead and use the measured voltage drop across this resistor to calculate the current. For example, if the measured voltage across the resistor is 1.5 volts, then use Ohm's law to determine the current: $I = E/R$ or 1.5 volts/100 ohms = .015 amp or 15 milliamps. The base current can also be calculated by measuring the voltage drop across the 10k resistor R7. The Hfe, or gain, of the transistor can be calculated by the formula $Hfe = Ic/Ib$ where Ic equals collector current and Ib equals base current.

I hope that this transistor/diode test set proves to be a valuable part of your test gear. If you find a modification that enhances it, I'd like to hear from you!

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

Well, about all that comes to mind is that wonderful old song which goes, "Though April showers may come your way / they bring the flowers that bloom in May." While we have had our share of precipitation here in the mid-Atlantic states, blooming here at WA3AJR are your questions, and what questions they are! This month brings a pack of real problems.

I'll start with one from Wayne Grove K9SLQ, who writes that he recently uncovered his Model 28 in the garage, picked up a tape recorder and TU, fired the sucker up and enjoyed the sounds again from the ol' 28. Well, his question is, "Where can I find some of the old PIX we used to send in file form? I combed your articles but could not find any mention of the PIX in the 'Good Ol' Days'."

Well, Wayne, several years ago I ran an entire feature on TTY pictures, some of them quite complicated. In fact, it seems to me that for some years there was a competition on the air to see who could come up with the most creative picture. Some of them were *very* creative, indeed! Unfortunately, with the onslaught of computer terminals, many of which sported a different line length than teleprinters, and few of which could back scroll to view transmitted pictures, it seems to have gone out of vogue. I have asked several times here in the column for submissions, and have received none. So, unless you happen to run across someone with a good collection of old paper tapes, I am afraid that this may well be one area where the computer is just not as much fun as an old mechanical printer.

With the recent demise of AEA, as reported in this column a bit ago, we are beginning to see more unanswered questions about some of their products.

Such a question comes from Chris Cieslak AA9HD, who writes: "I've been using RTTY now since last summer, starting with the HamComm circuit and recently graduating to a used PK-232 bought at the local hamfest. (The first time I used it after replacing a few parts and cleaning it up was the RTTY Roundup—talk about trial by fire!) I have one question: Do you know of any home-brewable scope-style tuning circuits for the PK-232, which has outputs on the back for a scope? The tuning indicator on the front is nice, but I've always liked the cross displayed on a scope. I know I could use an old hamfest scope, but my limited shack space and sense of aesthetics requires something a bit smaller."

Well, Chris, I'm afraid that the short answer is "no." I have seen a few circuits in the past for LED-type display boards, but these were years ago, and relatively clumsy by today's standards. I would not be surprised, though, if some reader of this column has not already put together such a device. If I hear about it, I'll print it for all to benefit.

Another AEA user, Ron Modeste N3AHD, bought an AEA CP-1 at a local hamfest, and is looking for a way to copy RTTY or CW with an IBM-style computer with this device, designed for the C-64. Well, Ron, while I have printed a lot on the CP-1 over the years, never has anyone written with a connection scheme for the PC. Somehow, I feel this is possible, but not having access to a CP-1 nor full documentation, I am loath to suggest a way. If any of our readers have done it, I'm sure we will both hear about it, real soon!

Not satisfied with one question, Chris Cieslak AA9HD adds:

"Oh, OK. One more question. Have you heard anything about using the ICOM 728 for RTTY? I've been using it full power for a while and while it's gotten quite warm, it wasn't hot enough to burn or anything. The manual mentions nothing pro or con on keydown RTTY. *QST* says the radio was barely warm after several minutes of keydown full power, but what about repeated use? I love RTTY and operate it more than anything else (except maybe SSTV) so I'd hate to have to turn the power down."

While I have not heard any specific information about the ICOM 728, in general, most modern rigs should not be run wide open, key down, for any length of time. I hear you about getting only barely warm, but that's on the outside. Who knows how warm it is at the component level? I'd play it a bit safer and back the power down a notch. After all, in the scheme of things it may only be a decibel or so difference on the air, versus a decade or so life of the equipment. I'm open, of course, for comments on this one, as well!

Ford A. Peterson NØOQW writes that he is looking for software to run his HAL Communications ST-6000. He indicates that an old program, HAMRTTY, worked well, whereas the newer Hamcomm program does not compare. He wonders which of the newer crop can use all of the features of the ST-6000.

Well, Ford, my experience with HAL devices ended with the ST-6, I'm afraid. [...Why are you afraid, Dave?] I do recall that the ST-6000 had some gizzies that took it head and shoulders above other demodulators of its time, but although I looked through some of the packages in the RTTY Loop Software Collection, I did not see any which specifically mentioned the ST-6000. I would be interested in any reader's experience with this TU in modern systems.

Of course, things can get *too* modern! A while back we were talking about using various sound cards on RTTY, and Tom Petruzzelli WA2ANG is "still looking for any programs that use the Soundblaster card for sending or receiving RTTY and/ or CW. Do you know of any software either commercial, freeware or shareware?"

Well, Tom, while I was not able to find any RTTY program for the Soundblaster card, I have located a program called SSTVBL.ZIP, which allows slow scan television with a computer, Quick-Cam camera, and Soundblaster card. I've also found a program called SBPMORSE.ZIP which is a Morse code reader using the microphone input of the Soundblaster card. I don't know if these will run with "compatible" sound cards, as they both list the Soundblaster by name as the audio card of choice. I will be putting both of these programs onto a disk in the RTTY Loop Software Collection. See details below for how you can obtain any or all of these programs for yourself.

While some of the folks mentioned above have been trying to get C-64 hardware, like the CP-1, to run with PCs, Jerry Olson WBØAAC says that he is looking for software to interface his Commodore C-64 computer with the Kantronics UTU demodulator, for running RTTY, AMTOR, or CW. Again, I can't see why it shouldn't work, if the connections can be put together. Anybody?

I have mentioned the RTTY Loop Software Collection above. The listing of this collection, over fifteen disks of RTTY programs for DOS and Windows operating systems, is detailed on the RTTY Loop Home Page, on the Web at: http://www2.ari.net/ajr/rtty/ or you may obtain it by sending a self-addressed, stamped envelope to the above address. Next month, I have a new offering from overseas, which represents a unique merger of two ends of this crazy hobby. Intrigued? Don't miss next month's RTTY Loop! 73

Above & Beyond

VHF and Above Operation

Modifications to the MFJ-259/219 SWR Analyzers

I just hate to turn on a piece of test equipment and find the batteries dead. I would rather have the batteries discharged and recharge them than have to purchase a replacement set of alkaline batteries. Considering the current price for alkalines and the cost of NiCds, the latter become very attractive—especially after you purchase your second set of the former. The trick here, though, is that the battery connector on the MFJ-259 SWR analyzer is for an external battery. When an external battery is connected, it disconnects the internal alkaline pack.

I had to modify this operation so that I could use external batteries if I wanted to, as well as charge an internal NiCd pack. These modifications were to be made in such a manner that the MFJ-259 was protected from reverse voltage and its basic operation not affected. The problem here was that the original connector, when hooked to an external battery, cut off the ground connection to the original internal battery pack. When installing NiCds, avoid this by shunting around the switch with the current-limiting resistor.

Several cautionary notes need to be observed when making a modification like this. The paramount thing is to make the external connection *idiotproof*. Make the modification impervious to reverse-connected DC power. Wrong polarity connected, nothing happens—a great insurance policy that provides a great deal of protection for the cost of a small diode rectifier like a 1N4002.

The last thing you would want is to connect power and destroy this SWR meter. My garage is littered with carcasses of car stereos and other toys that were rewired for little experiments, only to be subjected to momentary loss of sanity (polarity) and quick destruction. If you do something like this modification, please take the time to do it right. The modification has to account for (1) reversed polarity; (2) supplying a trickle charge to the NiCds instead of a fast one; and (3) retaining the original external power connection to keep the unit's original appearance. See **Fig. 1** for the original power connections circuit and how it was modified with internal NiCds to accommodate the new charging options.

I have oriented the PC board to show the unit face down and with the back cover removed. I placed the UHF connector up, or at 12 o'clock. Note the connector for external power and its three solder tabs. The top connector is common board ground, the one at lower right is switched to ground (internal to the power connector socket), and the bottom left one is the center connector or +DC voltage. The +DC connection also has a wide trace going to the on/off switch center connector. This trace will be cut and replaced with a rectifier diode for polarity protection.

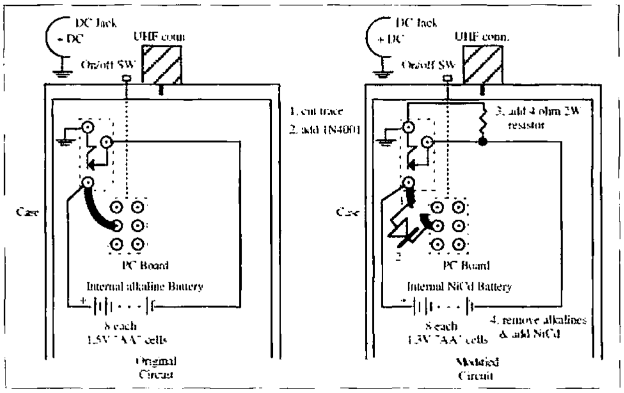

Fig. 1. PC board prior to modifications, and after modifications with DC polarity protection and NiCd 4-ohm current-limiting resistor added.

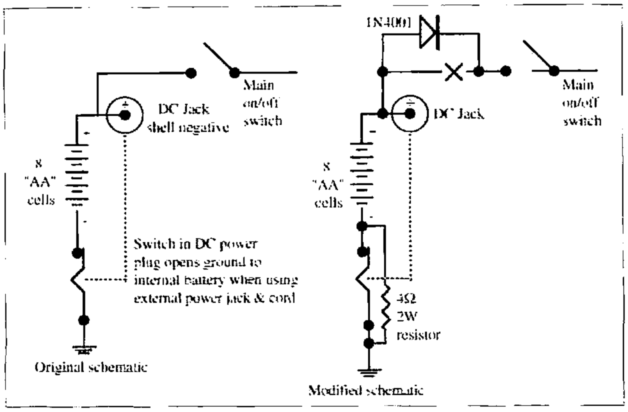

Fig. 2. Basic input electrical schematic circuit of original and modified circuit for NiCds and current-limiting and diode-protection circuit.

This diode will not protect the NiCds from reverse charging, but will protect the electronic circuitry of the MFJ SWR meter. To protect the NiCds from reverse charging, add another rectifier diode in series with the 4-ohm resistor connecting diode cathode to ground. Current-limiting is done by the 4-ohm 2-watt resistor that ties the ground and switched ground together as shown in **Fig. 2**.

Consult **Fig. 2** for a brief schematic of the standard circuit before and after modification. You can use this as a guide to "ohmmeter out" the exact points of modification from the power connector to sort of test it prior to modification—just to be sure you and I are talking about the same connections and don't have any misunderstanding.

I have to tell you that operation with NiCds (8 each) will produce about 10 volts. The protection diode will drop that voltage to 9.3 volts for feeding the meter circuits. This is sufficient to operate the meter, but if you are a purist there is a more sophisticated meter polarity circuit that you can install. Normally this circuit is reserved for situations that can't withstand a protection diode and its associated voltage drop.

The no-voltage-drop circuit is accomplished by adding to the original circuit a diode and DC relay. The diode is connected in series with the DC-relay main coil. This circuit (diode and relay coil) is connected between the main DC power input and ground, with the main DC power to the circuits it is going to protect passing through normally-open relay contacts.

When correct polarity is applied, the relay operates and its contacts close, applying the correct-polarity DC through to the circuit being protected. What happens if reversed-polarity DC is connected to this same protection circuit? The diode in series with the relay coil will not allow reversed current to flow to operate the relay coil. It will prevent the reversed battery from operating the relay coil and save the equipment from possible destruction. See **Fig. 3** for details.

Do not test this circuit and mechanically operate this relay, as you will destroy the circuit you are trying to protect. Let the DC voltage operate the relay when the polarity is proper. Remember, the protection circuit can be overcome by manual intervention if someone pushes the relay and closes its contacts. Just don't try to force its operation.

These modifications are quite simple—but don't rush into the project thinking it's a cinch. Take care even when doing an easy project, and don't be overconfident. That's when simple projects can become easy miscalculations. Think it out and verify everything with an ohmmeter to be sure of just what you are doing. And be aware that *any* modification might void your warranty on a new unit.

I constructed my 4-ohm 2-watt resistors out of two 2-ohm units; wrapped them in heat shrink to insulate them; and then formed the leads and soldered them to the PC board.

The DC power trace feeding the on/off switch was cut in mid-trace position with an X-Acto™ knife. The protect diode is installed with the cathode end towards the on/off switch. Any suitable diode or resistor combination will do the job here, and values or exact parts are not necessary.

The MFJ meter will function as originally intended with the exception that it now has internal NiCd batteries that can be charged from the external connector. The meter can be operated from either the internal NiCd batteries or the external (charging) DC power cable. (Note: The batteries will always be under charge through the 4-ohm limiting resistor in the NiCd battery ground circuit when using the external power option.)

After the modification is complete, the meter can be used with either power feed option, internal or external, and retain its original feel and appearance. I have used my meter with this modification for about 6 months and find it to be very good. I have left the power switch on, or it got bumped on, and I did not notice it. The benefit now is that whenever I pull it out for use I don't have to worry whether the internal batteries are ready to go. If they aren't, I stick it on a bench charger for a fast charge cycle and it's ready for use in less than half an hour.

Of course, NiCds being what they are, I don't get a lot of capacity time in a half hour charge (although it usually is sufficient). With a little planning the night before, you can charge it up overnight, saving the cost of a new set of alkaline batteries.

The MFJ-219 450-MHz SWR analyzer

While the MFJ-259 will work the full frequency spectrum from 2 MHz to just over 170 MHz, what can be done for 1-1/4 meters (450 MHz)? Well, they also make an SWR meter (the MFJ-219) with internal generator for the 450-MHz frequencies. I picked one up, tried it on the 432-MHz antenna project, and am happy to report it works just fine. And while this meter is touted to operate from 420 to 450 MHz, I discovered it has a few other extra benefits.

I found the 219's frequency readout scale to be inaccurate outside the amateur bands markings. Using the calibration markers to their extreme, I found that the unit I have will function from 410 MHz to slightly over 465 MHz. This allows measurements in the commercial portion of the 450 MHz frequencies to nearly 470 MHz. I suspect it could be coaxed up there, if that is your interest, by a slight tweak of the oscillator coil. To know what frequency the meter is set at, use the external frequency meter connector and get a direct readout.

This unit is quite a bit smaller than the VHF (259) one and the circuitry is quite dense. There is just about enough room for the two alkaline 9-volt transistor batteries. If I were to make a similar NiCd modification to this MFJ-219 unit, the 9-volt variety would still have to be retained even though there is not much time-to-current capacity in this type of battery. The bottom line is that there is no room for a larger battery. The electronics package takes up most of the case interior and thus this unit will stay unconverted for the time being. I am shopping for 9-volt NiCd bargains and will modify the unit when they are picked up.

The alkaline variety of 9-volt batteries will give good performance, but due to their cost and limited mAH capabilities, you think twice about leaving this unit on for extended periods of time. To conserve the 9-volt batteries, I recommend you make your test and then turn the power off until the next one. Life is not all that bad, as I left the battery switch on for a half hour while transporting the unit from a field trip and still had battery life to operate it. It's just that I am now on the verge of purchasing a replacement set of new 9-volt alkaline batteries, and that tugs on the wallet.

My recommendation here, due to the limited size, is to keep the alkaline batteries and get an external power connector and 12-volt rechargeable battery to use for extended test sessions. For you purists out there, the dial calibration in the amateur segment is quite good for reference use. However, for band-edge operation you might be well advised to attach an external frequency meter to the sample port for accurate frequency readings. Operation with the external frequency meter removes all doubt as to your exact frequency.

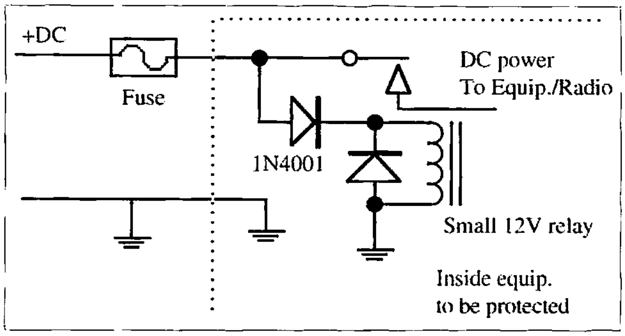

Fig. 3. Alternate no-voltage-drop reversed-voltage-protection circuit using a DC relay and a small diode rectifier. Relay will not operate unless the polarity is positive on the input lead, which then closes the relay contacts. Select a relay with contacts that will carry the amperage of the unit you are trying to protect.

There are several adjuncts that can prove to be very useful with the MFJ-259 SWR analyzer. This little self-contained unit intended for aligning antennas can be put to use in many other applications, making it very versatile.

Both the 259 and the 219 can be used as a general-purpose bench signal generators to adjust circuits within their respective frequency ranges. Such a unit is not suitable for SSB narrowband receiver tests, but it can be a great help for workbench circuit testing when you connect it to a simple resistor attenuator diode detector arrangement. Testing resonant circuits like cavities and other bandpass circuits is quite easy. The SWR analyzer is not a tool that is used every day, but when it is needed for antenna analysis or other tasks, both of these units work well. Here is a brief rundown on the two SWR analyzers.

The MFJ-259 HF/VHF unit is capable of operation from 1.8 MHz to 174 MHz in a six-band step arrangement. The output of the signal generator is nearly 200 mW. The high power output can be quite useful in adjusting circuits that need to be attenuated, such as cavities that are out of resonance. The power output can be adjusted with an external resistor step attenuator as you get near resonance and lower loss. Used together with the internal frequency readout indicator, this makes for a very powerful bench signal generator.

As with all basic units, there is always something more that can be added to a device to make it more useful. The analyzer as it comes from the factory is quite a powerful tool that is usable with ease to adjust antennas in its frequency range. One more stock feature might make this unit really shine. It would be to add a protective case to allow outdoor use without subjecting the analyzer to rough handling and perhaps accidental jarring. The MFJ-29 case, available separately, is not expensive ($20) and affords the meter a good deal of protection. I found a small Tektronics pocket o-scope case at our local swapmeet (for a buck) to protect the meter, and it works well.

The MFJ-219 UHF SWR analyzer doesn't need a carrying case, as it is more robust than the more delicate 259 meter with its LCD display to protect. I provided a case for my unit, as I don't want it to get tossed around. After all, it's still a precision instrument that needs protection if you expect to make reasonable test results. I am on the lookout for a single carrying case for both units and their accessories, and have been looking at the feasibility of some small computer laptop case for this purpose. There are a lot of surplus laptop computer cases on the market for very reasonable prices, so we will see what turns up. 73, Chuck WB6IGP.

Color me video!

For the past few months, we've been exploring the development of television, and the makeup of video signals. This time, let's take a close look at the color, or "chroma," signal.

As I mentioned last time, it was decided that the color information could be separate from the brightness, or "luminence," portion of the picture, and could be hidden on a subcarrier riding on the baseband video itself. (By "baseband," I mean the actual video signal, rather than the radio signal coming from a transmitter.) We took a look at the basic scheme: a high-frequency signal, non-harmonic with the line scanning rate, simply added to the video signal. But how do you get that one signal to represent the two essential color elements of hue and saturation?

Matrix!

If you're familiar with FM stereo broadcasting (which came much later, but that's irrelevant here), you know how two signals can be added and subtracted from each other algebraically. Hmmm, let's take a quick detour and go over it; the concept is crucial to understanding color video signals.

To add two signals, you feed them through resistors which meet at a common point. To subtract them, you invert one first (turn it upside down), and then do the same thing. The resulting voltage at the common point will represent the combination of the two signals, either an addition or a subtraction, depending on whether one of the signals was inverted. And, of course, that voltage will move up and down as the signals change.

In stereo audio, there are two items to represent: left and right. So, you can create two matrixed signals: L+R and L-R. FM stereo sends the L+R signal (which is simply a mono mix of the two channels) on the main carrier, and sends the L-R signal on a subcarrier. That way, a mono receiver will hear a normal mono signal, while ignoring the L-R subcarrier. The stereo receiver, though, will detect the carrier, recover the L-R signal, and then mix it twice with the L+R signal. Twice? Yes—one mix will be an addition, which will produce (L+R) + (L-R), which equals 2L + 0R, or simply 2L. The other mix will be a subtraction (by inverting one of the signals first), which will produce (L+R) - (L-R), or 0L + 2R, or simply 2R. Thus, the L and R signals are recovered. Pretty slick, huh?

Color TV used the same idea, but it was a little bit more complicated. Since there were three colors to represent (red, green and blue), the matrix consisted of three elements. Sending three elements on one subcarrier, though, would have been rather tricky, as it would have required sequential timing circuits, tough to implement with the vacuum tube technology of the day. Sending two, though, wasn't overly hard, as any AC wave (such as the subcarrier) has two polarities, positive and negative, which can be used to represent two elements of information, and then be separated at the receiver. Was there a way to reduce the matrix to two elements and still recover all three colors?

Ta da!

In this case, yes. Luckily, the luminence signal was there, too, and could be used as part of the equation. Let's see how they did it:

The luminence signal, called "Y" (Y call it that?—I don't know), was used as a reference. It, of course, was just an addition of R, G and B. By subtracting Y from each individual color signal, R-Y, G-Y and B-Y were produced. Then, the G-Y signal was simply discarded! What?? How could they ever recover the green information if they threw G-Y away?

In order to grasp the recovery of the green signal, it's important to keep the relationship of Y to the chroma signals in mind. Remember, the Y signal is a combination of all three original, pre-matrixed red, green and blue signals. So, if you recover the R-Y and B-Y signals (we'll get to how they did that, in a moment), and then add Y to each of them, you've got the R and B signals back. Now, add those together and subtract the result from Y, and what's left is the amount of G that was in the Y signal. In other words, green, which was hiding in there all along! This is a classic, if convoluted, case of solving for one missing variable when the other two are known. It's detective work, more or less.

> **"Sending three elements on one subcarrier would have been tricky with the vacuum tube technology of the day."**

Ride 'em, subcarrier

Since Y would be available at the other end of the process, this crazy thing could actually work—but the problem of how to encode R-Y and B-Y onto one subcarrier remained.

Remember when I mentioned that you could use the two polarities of the subcarrier independently? Well, why not? What if you used the amplitude of the negative peaks, say, for the B-Y signal and the amplitude of the positive peaks for the R-Y? Would that work? It sure would! (Actually, I don't remember which peak was used for which, and my video reference books are all packed away. But it doesn't matter; the principle is the same.)

OK, it was in there, but how the heck could you recover that information? With a normal, symmetrical AC waveform, the center, or zero-crossing, line is easy to find. But this thing would be riding along on top of the Y signal, so its center line would be wandering all over the place! Simple amplitude detection of the positive and negative peaks wouldn't work.

Synchronize your crystals!

The answer lay in synchronous detection. That's just a fancy way of saying that the receiver regenerates the equivalent of an unmodulated subcarrier, and then compares it to the real one. The unmodulated one tells the receiver when the positive and negative peaks should occur, letting it examine each polarity separately. In other words, time, rather than amplitude, is used to find the occurrence of the two polarities.

How to do that? Luckily, quartz crystals are pretty stable. If you synchronize a crystal oscillator to a reference signal, and then remove the reference, the oscillator will stay in "blind sync" with the reference for a short period of time before drifting off into never-never land. You'd never get away with that sort of thing using an LC oscillator, but it works with a crystal. Of course, a "short period" is a subjective quantity. Luckily for color TV, that time period only needed to be 62.5 microseconds, or the length of one horizontal line.

So, a reference signal was placed at the very end of each horizontal sync pulse. Called the "colorburst," it consisted of about seven cycles of the unmodulated color subcarrier frequency. It was easy enough to create a "burst gate" circuit which let *only* that signal pass, since the horizontal sync could be used to trigger the gate. The reference burst could then be used to sync the crystal oscillator, with new color sync occurring at the start of each horizontal line, right after the horizontal sync pulse, and before any picture information would be displayed.

Using the phase-locked crystal oscillator as a time reference, the synchronous detector could extract the values of R-Y and B-Y encoded on the opposite peaks of the subcarrier. All it had to do was examine the voltage value of the subcarrier when the reference was in, say, the positive state, and assign that to R-Y, and then do the same when the reference was in the negative state, and assign that to B-Y. Thus, the two signals were split off and recovered, and then sent to

the matrices that recovered green and finally outputted R, G and B! All that was left was amplifying them, sending them to the picture tube's electron guns, and enjoying the resulting color picture.

Whew!

I realize that was pretty complicated—it might pay to read it over a few times and let it sink in. Basically, it was all a clever matrixing scheme, designed to fit a color picture into nearly the same bandwidth as a monochrome one. And it worked!

Almost perfect

There was one little anomaly, though, and we live with it today. Although the colorburst signal did provide a reference for the synchronous detector, it didn't say anything about how accurately the transmitted color values represented the picture. And, unfortunately, various TV stations and networks weren't too uniform about that. Plus, phase shifts in the TV's circuits could throw the process off even further. So, even though the TV set might seem to be working perfectly, sometimes the color was off. Enter the hue control.

By varying the phase of the synchronous detector's reference (from the crystal oscillator), values intended for one color could be made to appear in another color, because the detector would be looking at the wrong part of the waveform, due to the time difference. As the phase was continuously varied, the hue of the picture would shift. The hue control, which shifted the reference oscillator's phase, could be manually adjusted to get everything in line for the best perceived picture. By the way, some other TV systems, in use in other parts of the world, have reference signals that eliminate the need for a hue control. Oh well, that's the price we paid for being first in color TV.

The upshot of all this color encoding is that color signals are very time-sensitive. So what? Well, it all works fine for live broadcasting, but it played havoc with the development of color video recording. Next time, we'll begin exploring the recording of TV signals. It's a fascinating topic in and of itself. Until then, 73 de KB1UM.

Barter 'n' Buy

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, **Barter 'n' Buy,** costs you peanuts (almost)—comes to 35 cents a word for individual (noncommercial!) ads and $1.00 a word for commercial ads. Don't tell a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old-timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine*, Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the August 1997 classified ad section is June 5th, 1997.

Continued from page 55

me with a lifetime of adventure and, apparently, no excitement or adventure for you. Oh, I've tried to get you interested in our ham satellites. I failed. I've tried to get you on slow scan. Failed again. I've tried to get you up to 10 GHz, where I worked seven states. No sale. I've talked up DXpeditioning. Even mini-DXpeditioning to the Caribbean or some nearby spot like St. Pierre. Another blank.

And when I write about the fun I've had doing the above I get carping crapola about my ego. I haven't suggested doing anything I haven't done. And I'm just a guy who's been dumb enough to make his hobby his life's work. Hey, what could be more fun? But when I suggest that you consider getting out of the rat race of working for someone else and experiencing the freedom of having your own business, you just sink lower into your commuting rut and yawn. Get some smelling salts or a bottle of ammonia and come out of that hypnotic trance you've been in for the last few years.

Grumble.

Hey! Wake Up!

What is it going to take to blast you out of that rut you're in?

Rut? Me? Yes, you! If you are working for someone else—if you are commuting to work every day—if you are sick—if you aren't an exciting and interesting person. I've been-there-done-that.

When I was a kid I commuted to high school, an hour trip on the jam-packed New York subway every morning and afternoon. Then there was the time a few years later when I was an engineer at Airborne Instrument Laboratories in Mineola and commuted an hour each way from Brooklyn. I tried it via the subway and the Long Island Railroad, and I tried it driving the Belt Parkway and the Grand Central Parkway. Both ways sucked. But then I was in as deep hypnosis as you and didn't know any better. Yet.

I've been through the hiring and firing routines, complete with résumés and interviews.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the September issue, we should receive it by June 1. Provide a clear, concise summary of the essential details about your Special Event.

MAY 2 & 3

KINGSBURG, CA The Fresno ARC. Inc., will host its annual Hamfest at Riverland RV Park, 3 miles south of the town of Kingsburg, on Freeway 99. The hamfest will be held 7 AM–4 PM, Sat., May 3rd. Hams begin to arrive at the park on Fri. May 2nd, with plenty of RV parking available. Displays of new and vintage radio equip. and swap tables loaded with used radio equipment for sale or trade will be featured. VE exams for all classes. Information will be exchanged on new radio operations, new radio equipment, and operator techniques to improve work in disaster and emergency services. Contact *Fresno ARC, Inc., P.O. Box 783, Fresno CA 93712.*

MAY 3

CADILLAC, MI The Wexaukee ARC will hold their annual Hamfest, 8 AM–2 PM, at the Cadillac Middle School. VE exams for all classes at 1 PM. Adm. $5; 8' table $6. Setup at 6 AM for table holders only. Talk-in on 146.98 rptr. Contact Dan *KE8KU, Wexaukee ARC, P.O. Box 163, Cadillac MI 49601. Tel. (616) 775-0998.*

KANSAS CITY, MO The PHDARA will hold its annual Hamfest 8 AM–4 PM at the Kansas City Market Center, I-435 and Front St., south of Worlds of Fun. Vendor tables $40/ $20, flea market tables $10, radio club tables, call for price. Adm. $6 advanced, $7 at the door. Contact *Bob Roske WAØCLR, Box 28954, Kansas City MO 64188-8954. Tel. (816) 436-0069; E-mail [waØclr@juno.com].*

MAY 3 & 4

ABILENE, TX Abilene will again be the site for the ARRL West Texas Section Convention and the Key City ARC Hamfest. Prearranged setup for dealers and manufacturers on Fri., May 2nd, 4 PM–9 PM. Setup for all others, including dealers arriving late, will begin at 6 AM, Sat., May 3rd. For info and reservations, call *Peg Richard KA4UPA, (915) 672-8889* (leave a message, your call will be returned); or E-mail *[jimr@swconnect.net]*. Find more info on the Web site at *[http://www.acu.edu/~cummingsg/kcarc.html].*

MAY 4

BLOOMINGTON, IN The Amateur Radio Go Getters will host their 3rd Annual AA9HI Hamfest at Monroe County Fairgrounds, 8 AM–3 PM. Setup Sun., 5 AM–8 AM. VE exams reg. at 11 AM, testing starts at 11:30 AM. Inside vendors: $5 per table, $5 per elec. hookup, $5 per ticket. Outside vendors: $5 per flea market space, $5 per ticket. Talk-in on K9TC rptr. 146.895(-) MHz (Tim Crafton K9TC). Contact *John Anderson AA9HI, (812) 332-3734 after 5 PM;* or *Randy Kinser KF9NA, (812) 332-3588 after 7:30 PM.*

HAGERSTOWN, MD The Antietam Radio Assn. will present the 5th Great Hagerstown Hamfest and Computer Show at the Hagerstown Jr. College, Athletic, Rec. and Community Center. Talk-in on 146.940(-) and 146.520 simplex, the night before and the day of the event. Adm. $5, children under 12 admitted free. Write to *Antietam Radio Assn., Inc., P.O. Box 52, Hagerstown MD 21741.*

WRIGHTSTOWN, PA The 23rd Annual Hamfest of the Warminster ARC will be held at the Middletown Grange fairgrounds, Penns Park Rd., starting at 7 AM. Setup at 6 AM. 8' tables $12 ea., pre-reg. recommended. Unlimited outdoor tailgating spaces $9 ea. Computer hardware and software vendors are invited to participate. Adm. $6, unlicensed spouses and children under 12 free. VE exams at 11 AM; reg. at 10:30 AM. Applicants bring original and copy of present license and/or certificates of successful completion, two forms of ID and the $6.25 examination fee (Novice class free). Talk-in on 147.09/.69 rptr. and 146.52 simplex. Contact *John D'Onofrio, 1255 Manor Dr., Warminster PA 18974-2102. Tel. (215) 675-9165, 9 AM–9 PM. E-mail [warc@crompton.com].*

YONKERS, NY The Metro 70cm Network will host a Giant Electronic Flea Market at Lincoln H.S., Kneeland Ave., 9 AM–3 PM, rain or shine. Indoor flea market only. 1st table, $19; each additional table $15, or bring your own tables at $14 for a 6' space. At the door, $25 each table, $20 ea. 6' space. Full payment due with reg. Adm. $6, kids under 12 free. Setup at 7 AM. For reg., contact *Otto Supliski WB2SLQ, 53 Hayward St., Yonkers NY 10704. Tel. (914) 969-1053.* Talk-in on 449.425 MHz PL 156.7, 223.760 MHz PL 67.0, 146.910 Hz, and 443.350 MHz PL 156.7.

MAY 8 & 22

FORT WORTH, TX The Lockheed ARC and the Kilocycle Club will sponsor VE exams for all classes at the Lockheed Rec. Area Facility, 2400 Bryant Irvin Rd., at 7 PM. For details, call *Ted Richard AB5QU, (817) 293-6745.* GROL testing done by appointment only.

MAY 10

GREENVILLE, SC A hamfest will be sponsored by the Blue Ridge ARS, 8 AM-5 PM, at the Anderson County Fairgrounds, E of Anderson on Hwy. 29 Business. Flea market, Buck Rogers, K4ABT SEDAN packet conference, VE exams at noon, overnight camping, free parking. Talk-in on 146.01/.61. Advance adm. $4; $5 at the door. Contact *Gene WB4ZBZ,* or *David KE4QQQ, (864) 476-2609, E-mail: [ke4qqq@innova.net].*

HURON, SD The Huron ARC will sponsor their 4th Annual Amateur Electronics Swapfest 8 AM–3 PM at the Nat'l. Guard Armory, SD State Fairgrounds. Flea market setup 7 AM, VE exams 9 AM. Talk-in on 147.09(+). Contact *Lloyd Timperley WBØULX, P.O. Box 205, Huron SD 57350. Tel. (605) 352-7896 eves.*

MEDINA, OH The Medina County Hamfest will be held at the Medina Country Community Center, 735 Rt. 42. VE exams at 9 AM. Tables $6, outdoor space $4, entrance $4 donation, $3 advance. Talk-in and directions on 147.03 rptr. For more details, contact *Medina Hamfest, P.O. Box 452, Medina OH 44258.*

MAY 15–18

DAYTON, OH The "Four Days In May"© QRP Symposium on Thursday, May 15th, held in conjunction with the Dayton hamvention©, will kick off QRP activities at Dayton. Full day of activities on Thursday at the Days Inn Dayton South (513-847-8422); includes multimedia QRP presentations, catered lunch, door prizes, tech talks, tutorials by clubs. Thursday registration $30 before May 1, $35 after (if still available). Make checks *payable to "Bob Follett" and send to: Bob Follett AB7ST, 2861 Estates Dr., Park City UT 84060, E-mail: [bfollett@ditell.com].* On Fri., May 16th, the QRP-ARCI Awards Banquet will be hosted by FDIM Banquet Chairperson Pete Meier WK8S. Please send $15 banquet ticket fee (US check, MO, internat'l MO) *made out to "Pete Meier"* by May 1st. Mail to *Pete Meier WK8S, 4181 Rural, Waterford MI 48329;* or *E-mail [pmeier@tir.com].* Also on the 16th, Preston Douglas WJ2V will host the FDIM QRP Vendor Evening Social. To register, contact *Preston Douglas WJ2V, QRP Vendor Evening Chairperson, 216 Harbor View N., Lawrence NY 11559,* or via *E-mail: [pdouglas12@aol.com].*

MAY 16

DAYTON, OH The southwest Ohio Chapter of the Quarter Century Wireless Assn. will hold its 1997 Annual Banquet in conjunction with the Dayton Hamvention. Alex's Continental Restaurant, 125 Monarch Lane, is the location for a C.O.D. bar at 7 PM, and a banquet at 7:30 PM. Reservation deadline is May 14th. QCWA membership is not a requirement for attendance. Tickets are $15 ea.; make check payable to *Robert L. Dingle, Treas., Chapter 9,* and mail to *1117 Big Hill Rd., Kettering OH 45429-1201.* Charles Stinger W8GFA, former mgr. of Voice of America Radio Station at Bethany OH, will give an inside look at this powerful transmitting station.

MAY 16, 17, 18

DAYTON, OH The Dayton Hamvention, sponsored by the Dayton ARA, Inc., will be held at the Hara Arena. Fri., May 16th: Flea Market open and bus service avail., 8 AM–

6 PM; Exhibits, Noon–6 PM; Forums 1 PM–5 PM. Sat., May 16th: Flea Market and bus service 7 AM–5 PM; Exhibits 8 AM–5 PM; Forums, VE Exams, Activities, 9 AM–5 PM; Hamvention Banquet at the downtown Dayton Convention Center, 6 PM. Sun., May 17th: Flea Market 7 AM–4 PM; Bus service available 7 AM–5 PM; Exhibits open 8 AM–2 PM; Forums and activities 9:30 AM–1:30 PM; Prize drawings 2 PM. Programs available Fri. at 7 AM in the Hara Arena lobby and in the tent in front of the East Hall entrance. Flea Market spaces are sold in advance only; a maximum of 3 spaces per person (non-transferable). Limited to amateur radio, electronic, and related items only. Electricity available in a portion of the last Flea Market row for $60 a space extra. Tables and chairs not available. Contact the *Flea Market Chairman by FAX at (937) 253-1289, by E-mail at [fleamkt @hamvention.org]*, or by *voice mail at (937) 276-6932;* allow 30 seconds for the phone routing system to transfer the call. Registration tickets in advance $13, at the door $15. Banquet tickets in advance, $25; after May 17th, if available, $30. Flea Market spaces $50/1 space, $110/2 adjacent, $220/3 adjacent; elec. $60 extra each space. Covered tent w/elec. $325 ea.

MAY 17

COLORADO SPRINGS, CO Pikes Peak Radio Amateur Assn. will host a hamfest at Doherty H.S., 4515 Barnes Rd. Adm. $4; 1st table $12, each additional table $10. AC limited to outside wall tables, bring extension cord. Free parking. Setup May 16th, 6 PM–9 PM; vendors 6 AM on the 17th. Talk-in on 146.97/100 Hz, and 146.52 simplex. Contact *Dennis Major KBØSXC at (719) 535-1160;* or *E-mail [DENNIS.MAJOR@MCI.COM].*

MAY 23 & 24

PASCAGOULA, MS The Jackson County ARC will hold its 3rd Annual Hamfest in the Pascagoula MS Civic Center, Jackson County Fairgrounds. Hours are 1700Z–2100Z May 23rd, and 0800Z–1500Z May 24th. Adm. $2.50 for 12 yrs and older, under 12 free. Tables $8 per 8'. Free parking. RV parking in designated areas only, electric only, no dumping station. Nearby hotels and motels at reasonable rates. VE exams available at 0900Z Sat., May 24th. Prearranged meeting rooms for any amateur organizations. Talk-in on 145.110(-). Contact *Charles F. Kimmerly (Kim) N5XGI, 19000 Busby Rd., Vancleave MS 39565. Tel. (601) 826-5811.*

MAY 25

HILLIARD, OH Flyers, sailors, and amateur radio operators are invited to come and search for that perfect bargain at the Franklin County Hamfest. The event begins at 8 AM at Franklin County Fairgrounds. Adm. $5 per person. Inside tables $5 ea. Outdoor space $5 per 4 wheel vehicle. Setup at 6 AM. Call for advance tickets. Overnight camping with electric hookup is available on the grounds. Contact *Chris Lind, P.O. Box 14281, Columbus OH. Tel. (614) 267-7779; FAX (614) 263-7934.*

JUN 1

MANASSAS, VA The Ole Virginia Hams ARC will sponsor the Manassas Hamfest and Computer Show at the Prince William County Fairgrounds, on Rte 234. Gales open to public 8 AM, tailgaters 7 AM. General admission $5, tailgating $5 additional per space. All activities are wheelchair accessible. Talk-in on rptr. 146.37/146.97 and 223.06/224.66. Unlimited tailgating space. For more information: Commercial vendors contact *Jack N4YIC at (703) 335-9139;* General information contact *Mary Lu KB4EFP. at (703) 369-2877.*

PRINCETON, IL The Starved Rock Radio Club Hamfest will be held at the Bureau County Fairgrounds, starting at 6 AM. Advance tickets are $5 with 4 stubs before May 20th, and $6 with a single stub at the gate. Camping and outdoor flea market area is free. 8' tables indoors are $10 ea. Talk-in on 146.355/.955 PL 103.5. Contact *Bruce Burton KU9A*, or *Debbie Burton N9DRU, 1153 Union St., Marseilles IL 61341-1710. Tel. (815) 795-2201; E-mail [brburton@mtco.com].*

QUEENS, NY The Hall of Science ARC Hamfest will be held at the New York Hall of Science parking lot, Flushing Meadow Park., 47-01 111th St. Vendor setup at 7:30 AM; buyers admitted at 9 AM. Free parking. Adm., buyers $5, sellers $10 per space. Talk-in on 444.200 WB2ZZO rptr, and 146.52 simplex. For more info, call, eves. only, *Arnie Schiffman WB2YXB, (718) 343-0172.*

JUN 7

TEANECK, NJ The Bergen ARA will hold its annual Spring Hamfest at Fairleigh Dickinson Univ. Buyer adm. $3, with XYLs and harmonics free. Seller adm. $10. VE exams. Talk-in on 146.790/.600. Contact *Jim Joyce K2ZO at (201) 664-6725 before 10 PM.*

GRAND RAPIDS, MI The annually sponsored IRA Hamfestival will be held at Hudsonville Fairgrounds near Grand Rapids. Doors open at 8 AM for general adm. Dealers can set up on the 6th after 7 PM, or after 6:30 AM on the 7th. Overnight camping. Bring your equip., etc., to sell and trade. VE exams at 8:30 AM. Talk-in on 147.16 link rptr. system. Reserve early for the best spots. Indoor table space and trunk sales spaces available. Contact the IRA voice mail/info line at *(616) 534-6803;* or *Tom KA8YSM* or *Kathy KB8KZH* at *(616) 698-6627.*

SPECIAL EVENT STATIONS

MAY 2, 3 & 4

FALL RIVER, MA W1ACT, the Fall River ARC's annual DXpedition to Martha's Vineyard (IOTA-NAØ46), and Massachusetts QSO Party, will operate on the following freq.: CW—1810, 3550, 7050, 14050, 21050, and 28050; SSB—1850, 3890, 7290, 14260, 21390, 28390, 146.550, 446.000 (FM), 434.0, and 439.25 MHz (ATV). Send an SASE for QSL via *N1JOY, 19 Davis Rd., Westport MA 02790. E-mail [roland-d@ici.net].*

MAY 3

NOVI, MI The 1st Annual Novi Special Race Car (Indy 500) Celebration will be sponsored by the Novi ARC, 1400Z–2100Z. The club will use the callsign KC8FSW. Freq.: CW—7.030, 7.125, 21.050, 21.150; PHONE—14.225, 14.250, 14.300, 21.325. Please request "Car Photo QSL." QSL to *N.A.R.C., P.O. Box 268, Novi MI 48376-0268.* For more info, call *Greg Tullar KB8UBL at (810) 474-3633.*

MAY 3–4

DANBURY, CT The fabulous 1997 Connecticut QSO Party will be sponsored by the Candlewood ARA, 2000Z May 3rd–2000Z May 4th, with a rest period 0400Z–1200Z. Phone, RTTY and CW. For operating rules, contact *CARA, P.O. Box 3441, Danbury CT 06813-3441 USA.* Please remember to send an SASE.

PHILADELPHIA, PA The Olympia ARC will operate WA3BAT from 1300Z May 3rd–2000Z May 4th, to commemorate the 99th anniversary of Admiral Dewey's triumph over the Spanish fleet at the Battle of Manila Bay. SSB/Phone: 3.898.5, 7.248.5, 14.248.5, 21.368.5, 28.368.5, 145.270 FM. CW: 3.710, 7.030/.110, 14.030, 21.040/.110, 28.025. For a certificate, send QSL and a 9" x 12" SASE to *Olympia ARC, Independence Seaport of Philadelphia, 211 South Columbus Blvd., Philadelphia PA 19106 USA.*

MAY 10 & 11

FLOYD, VA The Foundation for Amateur International Radio Service (FAIRS) will operate FAIRS Club stations N4USA, US5WE, BY1QH, 8R1WD AND S21AM, to celebrate the 6th anniversary of FAIRS. Freq.: General portion of 40, 20, and 15 meters. For a certificate, send QSL and a 9" x 12" SASE to *FAIRS, P.O. Box 341, Floyd VA 24091 USA.*

MAY 17

TAMA, IA The South Tama ARS will operate WDØGAT 1500Z–2300Z to celebrate the annual Lincoln Highway Bridge Festival. Operation will be in the General 40–15 meter phone, Novice 10 meter phone, and 2 meters. For a certificate, send your QSL and a 9" x 12" SASE to STARS/WDØGAT, P.O. Box 94, Montour IA 50173.

MAY 31

NEW PORT RICHEY, FL Pasco County RACES "Disaster Fair," will be held 1300Z–1700Z on 14.225/.275 and 28.400(±) QRM. For a certificate, contact *Michelle Baker, EOC, 8744 Government Dr., New Port Richey FL 34654 USA.*

Number 80 on your Feedback card

HOMING IN

Radio Direction Finding

Joe Moell P.E. KØOV
P.O .Box 2508
Fullerton CA 92633

Many hams can't imagine turning a VHF beam or quad in a moving car, but it's a common sight here in southern California and lots of other places. When signals are weak, nothing else pulls them in and gives sharp directional bearings. What's more, nothing works better when the signal you're hunting is horizontally polarized.

As you remember from studying for your Element 2A test, the orientation of an antenna's radiating elements determines the polarization of the electrical component of the transmitted or received RF wave. Let's say that the path between a transmitter and receiver is line-of-sight. Transmit and receive antennas are polarized at right angles, one horizontal and one vertical. This cross-polarized condition results in the signal at the receiver input being weaker by as much as 20 dB, which is the difference between full scale and zero on most VHF-FM S-meters.

Now imagine what happens when that perpendicularly polarized signal strikes a building, mountain, or other non-absorbing object larger than a few wavelengths. The signal will be reflected or scattered. The scattered signal will have polarization components that are horizontal, vertical, and all values in between. As a result, scattered signals will be stronger at your receiver input than a direct cross-polarized signal.

On a T-hunt, if the polarization of your RDF antenna is not the same as that of the transmit antenna, reflected signals will be enhanced relative to the direct signal. If the hidden T is in an area of high signal reflections and if the polarization you choose is perpendicular to it, you may chase signal reflections from start to finish. Unless the T-hunt rules in your area prohibit non-vertical polarizations, make sure your quad or yagi has provisions to adjust polarization to match the target signal.

The *T-Hunt Book* shows an easy way to put a slipjoint on your quad's boom/mast junction so you can turn the boom to vary polarization. The book also has lots of ideas for easy ways to mount the rotating mast of your beam or quad on your vehicle for safety and ease of use. For an all-electronic method of polarization selection, see "Homing In" for February 1997.

Getting RDF bearings with a yagi or quad is simply a matter of turning your beam for maximum signal and driving in that direction as roads allow. Your receiver's S-meter is usually better than your ears for detecting the signal peaks, so be sure to locate it such that it is easily viewed by the driver and any RDF helpers. When the signal is too weak to deflect the meter, turn for the clearest audio with best "quieting" of noise.

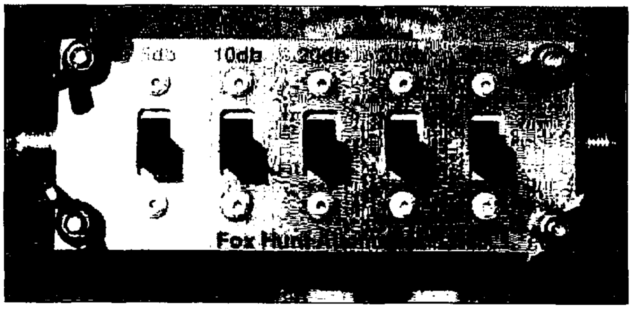

***Photo A.** You will need an RF attenuator for closing in on the transmitter with your beam or quad. This resistive unit was made by Arrow Antenna.*

As you get closer to the signal you're seeking, your S-meter will go to full-scale no matter where the beam is pointed. RF attenuation in the coax line from antenna to receiver will knock the signal down to within the meter's dynamic range. Resistive attenuators like the one in **Photo A** are easy to build at home from plans in the *T-Hunt Book* and the *ARRL Handbook*. FAR Circuits sells a solder-up RF-tight enclosure for your home-brew attenuator to save you a session at the shear. Wired/tested attenuators are available from Arrow Antenna.

Instant bearings from Dopplers

Yagis and quads are simple, inexpensive, and effective for two-meter mobile RDF, but they require the operator to turn carefully and interpret the S-meter readings. If the target signal is varying in power or pulsing on and off, it may be impossible to get an accurate bearing with a bouncing S-meter. On the other hand, Doppler sets do not use signal strength as a bearing criterion.

Dopplers have no moving parts—just an array of vertical whips (usually four) atop the vehicle. The display is a circular ring of light-emitting diodes (usually 16). Dopplers work in conjunction with your existing VHF-FM mobile transceiver, handie-talkie, or scanner, attaching to the antenna and external speaker/earphone connectors.

Switching diodes connect each whip to your receiver, one at a time in sequence. The receiver operates as if it were connected to a single antenna rotating around an invisible vertical axis in the center of the array. This pseudo-rotation causes FM modulation to appear, superimposed on the received FM signal as a tone at the rotation frequency. The phase of this demodulated tone, relative to the antenna switching sequence, determines the direction of the incoming signal.

From an ease-of-use standpoint, a Doppler is nearly ideal. One LED at a time comes on to indicate direction of the signal relative to the front of the vehicle. The top LED in the ring represents signal dead ahead. Dopplers take bearings several hundred times per second, so they can capture a signal of very short duration and hold the bearing to it when the signal goes off.

***Photo B.** Bandmaster quads for two meters are available with two, four or six elements. Note the SO-239 coax connector at the lower corner of the driven element.*

Many hams have successfully built their own Dopplers. The most popular such project for home construction is the Roanoke Doppler, which you can duplicate for less than $150. Complete plans for the display unit and a two-meter four-element antenna are in the *T-Hunt Book*. I recently designed an improved antenna system that is more sensitive, covers a wider frequency range and can be built either as a one-piece assembly or with four ordinary magnetic mount whips. See "Homing In" for April and June 1995 or the "Homing In" Web site for details of this antenna.

By building your own Doppler set, you will save money and learn about Doppler technology. For hams who aren't ready for that or who want more "bells and whistles," two commercial Doppler manufacturers have affordable products for the ham market. The 4000 and 5000 series models from Doppler Systems Incorporated feature a patented method of "soft-switching" the four whips to reduce cross-modulation effects. Prices start at $620 for an LED display unit plus four magnetic-mount whips. Higher-priced models add voice readout, digital bearing output and other advanced features.

NEVER SAY DIE

Continued from page 77

I was "downsized" when the TV station I was working for (KBTV in Dallas) shifted from live programming to all film, eliminating the need for a director for their live shows.

Okay, what's the first letter on the eye chart? That big one up on top? It's an E and for me it stands for entrepreneurialism. That's the subdivision of capitalism that works the best. And it's the key to your freedom from being hired or fired, from commuting, from being downsized, or replaced by a someone in Pakistan who's better educated than you and will work for 10% of what you've been pulling down.

If you're totally wasting an hour or two a day commuting to work, what do I have to do, come and shake you personally to get your attention? How can I get you to wake up and take charge of your life?

And the same thing goes for your health. You've heard the old saw about you being what you eat? Well, you know it's true, but as long as your body is able to survive the crap you've been eating, drinking and breathing, you make do with arthritis, an occasional heart attack, cancer, and other results of your gross neglect.

As far as your health goes, no, I'm not going to tell you what to do. But I am going to aim you at some books which I've found reliable which will let you educate yourself.

Those years you wasted in our public school system did *not* educate you. Wait'll you read some of the books on my list about that scam. It may almost make you mad.

Book list? It's a 28-page list of almost one hundred books I say you are crazy if you don't read. No, I don't sell the books—that would be a conflict of interest. The list includes a brief explanation of why each book will be valuable to you and how you'll benefit from reading it. I've reviewed many of the books in my editorials, but you've forgotten about 'em already. The list is a measly $5 from Radio Bookshop.

Just the books on health that I review can change your life, adding at least an extra 20-30 years of robust health to it.

continued on page 84

The DFjr from Agrelo Engineering is a new entry into the Doppler market featuring digital processing of bearing data. At $350, it includes the LED display and a set of four magnetic-mount whips on an aluminum crossbar frame.

Once the incoming signal is above the level necessary for a Doppler to acquire bearings, direction indications are independent of the signal strength. So how do you know for sure when you are close to the hidden T? When searching with a Doppler on my mobile transceiver, I remove the antenna from my handie-talkie, turn it on and place it on the dashboard. As the signal breaks squelch on the handie-talkie and becomes full-quieting, I am able to gauge my progress as I close in.

A Doppler is rapid-responding, convenient, and easy to mount on any vehicle, but it is not always the best tool for the job. In areas of high signal reflections, Doppler displays may dance wildly, making it difficult to discern a bearing trend. Because they do not use gain antennas, Dopplers are less sensitive than beams. Dopplers are seldom usable at the starting point of southern California's long-distance weak-signal hunts.

Sensitivity and accuracy of the Doppler method is degraded when the target signal is horizontally polarized. In that case, signal reflections are enhanced relative to the direct signal, making tracking much more difficult in urban or mountainous terrain.

The Doppler technique requires a receiver with FM detection, no matter what modulation is on the target signal. Doppler sets will not track non-carrier modes such as single sideband and pulsed noise. Bearings taken while the vehicle is in motion are usually more reliable than when stopped.

End of the road—time to sniff

Sometimes you can't drive all the way to the signal source. The spurious signal you're tracking may be inside a building. Which floor? What room? A hidden T may be in a field or a park, away from vehicle access. RDF on foot when you have driven as close as you can is usually called "sniffing."

International-style radio-orienteering contests are all sniffing, no vehicles at all. If you are tracking the beacon at the end of a high-altitude balloon flight, you may need to look miles away from the nearest road. Your mobile-mounted beam or Doppler isn't suited for these tasks.

A crude way to get bearings in the field is to use body shielding maneuvers with your handie-talkie. Directional antennas are far more effective, however. Usually you have plenty of signal when sniffing, so a small handheld beam of two or three elements is fine. The N6WZI yagi described in "Homing In" for May 1996 is a great do-it-yourself sniffing project. If you don't want to home-brew, consider the three-element yagi from Arrow Antenna or the two-element quad from AAE Bandmaster.

An ordinary resistive attenuator won't stop your hand-held receiver or scanner from being swamped by signals leaking through its case as you approach a hidden transmitter. To get bearings under these circumstances, consider an offset attenuator. The oscillator and mixer stages in this device shift the T's frequency by about a megahertz and control amplitude of the shifted signal. Just retune your receiver to the offset frequency and continue to take bearings. You can purchase an offset attenuator from Antennas West; plans for a home-brew version are in recent editions of the *ARRL Handbook*.

Another way to continue when the two-meter signal is too strong is to track its third harmonic with a dual-band handheld. Normally, harmonics are 40 to 60 dB weaker than the fundamental, so a beam for 440 MHz will get bearings on it to within a few feet. The Bandmaster Q-440-6 quad and the Arrow 440-5 yagi are small enough to tote along when you sniff. The Arrow 146/440-8 has separate elements and feedpoints for both two meters and 70 cm on the same boom.

I am nearly out of space for this month's column, but I'm not out of suggestions for VHF RDF equipment. Come back next time to learn about "buzz boxes" and field-strength meters. You will also find out what TDOA stands for.

My "Homing In" site on the World Wide Web [http://members.aol.com/homingin/] has a wealth of information to help you and your club get started in the fun of hidden transmitter hunting. You will find hot links to sites of many RDF equipment suppliers mentioned in this article. There are several detailed technical articles, including modifications and improvements to popular RDF products. One page lists sources of components and assemblies for home construction of RDF gear, including four makers of circuit boards and kits for the Roanoke Doppler project.

Want to find out about T-hunting in your neighborhood? Check the links page for Web sites and E-mail addresses of RDFers in over 40 urban and rural areas of North America. All of them are eager to hear from "Homing In" readers who might join in their hunt activities. There are even RDF-related links to 15 other countries around the world, most of them in English.

Even if you don't have Web access, I can put you in touch with RDF enthusiasts near you. Send inquiries via E-mail to [Homingin @aol.com] or via postal mail to the address at the beginning of the column. If your club has T-hunts and isn't listed at my site, be sure to let me know about that, too.

NEW PRODUCTS

You Need This Book!

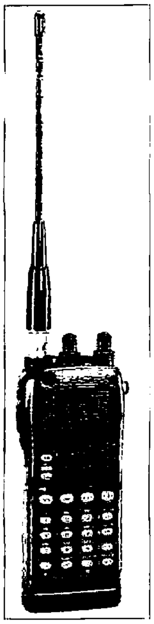
Ferromagnetic-Core Design and Application Handbook is new from MFJ Publishing. Written by the legendary designer Doug DeMaw W1FB, it's a quick, handy reference guide or good study manual for amateur operators, and it's only $19.95. It's also the only book that emphasizes the practical aspect of magnetic core materials from low frequencies through UHF.

DeMaw gives you an in-depth understanding of theory and many practical circuit examples using toroids, rods and pot cores of ferrite and powdered iron. You also get lessons about proper core selection versus operating frequency, circuit Q, power handling capability, and physical mass. Equations are used only when needed to illustrate a concept or design example—tedious mathematics have been omitted to make the *Handbook* easier to understand.

Order toll-free by calling (800) 647-1800; for more information or your nearest dealer, contact MFJ Enterprises, Inc., 300 Industrial Park Road, Mississippi State MS 39762. Telephone (601) 323-5869; FAX (601) 323-6551; or check out the Web site [http://mfjenterprises.com].

Happy 40th!

The Cubex Antenna Company proudly announces its new line of 40-meter antennas—the "Mantis." The Cubex 40th anniversary antenna, it's available in 2 and 3 elements, and up to 7 bands. Prices range from $1,199.95 for a 2-element 40-meter antenna on a 15 x 3 boom to $2,379.95 for a 7-band antenna featuring 4 elements on 10-12-15-17 and 20 meters and 3 elements on 30 and 40 meters. Contact Cubex for details: 2761 Saturn Street, Unit C., Brea CA 92821. Telephone (714) 577-9009 or FAX (714) 577-9124.



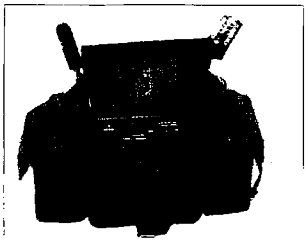
User-Friendly Handhelds

ICOM Inc. brings you the IC-W32A (US version) and the IC-W32E (Europe version) handheld high performance dual-banders to meet the demands of both the novice and the experienced operator: simple operation and advanced features.

The W32 series has separate tuning and volume controls for each band on the top panel, allowing independent adjustment of either band. A new function, the VHF/UHF exchange, allows you to assign VHF/UHF tuning and volume to either knob—set your preferred band to the knob that gives you easiest access.

Independent main and subbands let you receive both VHF and UHF simultaneously, or use the V/V or U/U functions for receiving two frequencies on the same band. There are 200 memory channels; assign a name of up to eight characters from the keypad, and, through the use of an optional cloning cable, transfer stored information from one IC-W32A/E to another. There's a ton more stuff you'll want to find out about, so contact your ICOM dealer or ICOM America, Inc., 2380-116th Avenue N.E., Bellevue WA 98004; phone (206) 454-8155.

More Power

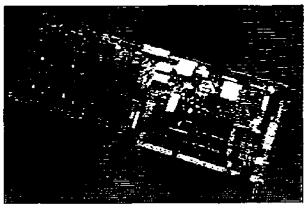


The new Powerport 149 from Cutting Edge Enterprises may be just what you've been looking for, if you need to run/charge radios, soldering irons, test equipment, emergency lights, laptop computers, video cameras, handheld GPS receivers, FAX machines, electric hand tools—pretty much anything that requires power.

The Powerport 149 weighs nine pounds, measures 4" x 4.5" x 6", and provides 140 watts of 115V AC (surges to 200W), and up to 20 amps of 12-volt DC power. It will keep a portable fluorescent light going for more than 24 hours, or a hand-held radio running for 80 hours. Can you think of an emergency situation that *couldn't* use one of these babies?

Powerport can be charged in your vehicle through the cigarette lighter without the engine running, or it can be left plugged into a wall outlet without fear of overcharging. Flexible solar panels are an option, as is the padded carrying case, with detachable accessory pouches.

For further information contact Roger Hall at Cutting Edge Enterprises, 1803 Mission St., Suite 546, Santa Cruz CA 95060; phone (800) 206-0115.



ST-108 Spread Spectrum Matched Filter Demod

SIGTEK, Inc., announces the release of the ST-108 Spread Spectrum Matched Filter Demodulator for cellular CDMA, satellite, and point-to-point microwave applications. The board supports direct sequence chip rates up to 30 MHz and data rates in excess of 2 Mbits/sec. The PC/AT compatible ST-108 is available with either a 70- or 140-MHz IF. Programmable digital filters shape and filter the input signal for optimum performance. A programmable 1024 digital matched filter provides instant signal acquisition. An optional daughter board adds powerful concatenated Convolutional/Reed Solomon Forward Error Correction.

The ST-108 is controlled through a sophisticated Windows 95™ interface that allows rapid setup of all key parameters such as input filtering, chip rate, spreading code, and data format. A DLL is also available for standalone applications. For more details, contact SIGTEK, Inc., at 9841 Broken Land Parkway, Suite 206, Columbia MD 21046. Phone (410) 290-3918 or FAX (410) 290-8146.

Manufacturers: your product releases could be here. Contact Priscilla Gauvin at: 73 Magazine 70 Rt. 202N Peterborough NH 03458.

NEVER SAY DIE
Continued from page 81

There's an awful lot of baloney out there in the alternative health field, so you need someone to sort things out for you.

Now, getting back to the big E. If you've forgotten the things I've written about that down through the years, you'll do well to invest $5 in my *Making Money, A Beginner's Guide*. Every now and then I get a phone call or letter from a graduate of Green's School of Entrepreneurialism thanking me for changing their lives. I want to get you to consider the freedom I offer and go for it so I'll get that letter from you in a couple of years.

The strength of our country lies in small businesses, not in giant industries. As far as I know, every big business is crooked and aiming to get bigger and bigger. When they get really big they become international and their interests aren't the same as ours. But with their money they have the power to pretty much control our country via hordes of lobbyists in Washington and every state capital.

So stop wasting your life working for someone else and start thinking about having your own business.

Darn, they're making soap boxes out of cardboard these days and they keep breaking.

Cancer!

A hundred years ago cancer was almost unknown. Today it will affect the lives of at least 50% of you. It's more like 100%, if you count your family. So what's gone wrong to bring on this epidemic, and how come the medical industry has been almost powerless to do anything about it?

As you read the books I've recommended on health you'll find that our medical industry is centered on treating symptoms, not getting at causes so that illness can be prevented. So what's causing this cancer plague? And what can *you* do to avoid being another victim? The major problem seems to be a weakening of our immune systems, caused by an increase in our poisoning ourselves. Poisoning? You bet! We're doing a real job on ourselves with stuff like aspartame (a.k.a. Nutrasweet™—the blue stuff), fluorides in our drinking water, chlorine ditto, dioxin ditto, dental amalgam (mercury poisoning), air pollution (how well are you filtering the air in your home and office?), keeping needed UVs out of our eyeballs, eating crap like sugar and white flour products, burgers and fries, meat laced with growth hormones, fruits and vegetables grown in almost totally mineral-depleted land. We're giving our bodies a fraction of the water it needs to flush out toxins. And have you read the list of chemicals they're putting into our foods to keep it from spoiling on grocery shelves? Do you really think that stuff won't collect and screw up your body? And I'm not even going to bother mentioning the effects of alcohol, cigarettes, and caffeine. Ooops, I almost forgot root canals and EMFs.

Over a million years or so our bodies developed to work best on the nutrients then available. Now we've changed all that and we wonder why we're doddering into nursing homes in our 60s instead of raising hell?

So we poison our bodies into sickness and then we go to the doctor and get an expensive medication. Another poison. The $1.5 trillion medical industry is controlled almost totally by a few major pharmaceutical companies. Their worst nightmare is an inexpensive cure for an expensive illness. And remember, nobody in the industry makes any money until you get sick. That's when you'll spend whatever they demand to get well. And this is happily supported by the insurance industry (you've seen their huge modern buildings, right?), which also has a large negative interest in your being healthy. When you get sick they pay, and that's known as cash flow. Then they charge higher premiums. They get their cut, so the more they have to pay out, the more profit they make.

Start reading the books on health on my list. The Comby book on a raw food diet. The Batmanghelidj book on water. The Wallach book on playing doctor. The Coca book on allergies. The Lane book on shark cartilage, which looks like one of the best answers to the cancer problem, once you've poisoned your body to that extent. Cayenne to avoid heart attacks.

The Bioelectrifier looks like it can help rebuild immune systems, and colloidal silver holds some great promises. I'll try to keep you up to speed in these fields as I learn more.

But if you keep putting sand and sugar in your gas tank, your engine isn't going to last long and you'll be doddering with your walker to hamfests. Or zipping around in one of those handicapped mobiles. So go ahead, hoist a few more beers and buy another carton of cigarettes.

I eat mostly vegetables and fruit these days. I'd eat more meat if I knew where to buy meat safe enough to eat raw. I love raw meat and raw fish. Sashimi. In Tokyo I was treated to a chicken dinner that started out with chicken sashimi and it was delicious. But the chicken we get from the supermarket is so laced with salmonella and other microbes that it's as dangerous as eating blowfish. Hey, I've got to find out more, but I'll bet a good dousing in silver colloids might make fish and meat safe to eat raw. Do you know anything about that? It seems reasonable, but I'm not yet ready to bet my life on it.

Yes, I've eaten blowfish. And survived. I recently saw the episode of "The Simpsons" again where Homer ate some and was told he was going to die in 24 hours.

Speaking (well, writing) of medical alternatives, if you think I'm alone in putting down the medical industry, do some alternative cruising of the Internet. Check out the Royal Rife Web page and see what that bunch has to say about the medics and their support by the feds, which is an incestuous relationship.

One of the books on my list is about Dr. Naessens, who, like Rife, but more recently, invented a super-powerful microscope. And he, like Rife, was thus able to see an even more basic form of life than the cell, one which seems almost indestructible. He called it a somatid. And he, like Rife, was persecuted by the medical establishment, complete with swat teams raiding his laboratory and destroying his notes and equipment. Well, he, like Rife, did a terrible thing: he found an inexpensive cure for cancer and used it to cure a bunch of people.

Screw the Generals

No, good heavens, not General Class operators—I'm referring to such generals as General Motors, General Foods, General Mills, General Instrument, and General Dynamics—the gigabuck conglomerates. Capitalism works first rate when it comes to smaller businesses, but it goes awry when corporations get big enough to dominate an industry.

I keep a copy of Ted Quinn's 1953 book, *Giant Business, Threat To Democracy*, at hand. Ted had been an insider, the vice president of GE, and saw what was going on when corporations get too big. Not only can they squash or limit their competition, they also have lobbyists in Washington to make sure that they have the government behind them in doing it. Larger corporations have lobbyists in every state capital too. I was amazed when I looked over a list of the registered lobbyists in Concord, my state capital.

The real strength of any country lies in the proliferation of small businesses, not in growing giants, which tend to be international entities, with it being irrelevant where the owner is.

For a while our government tended to keep a loose lid on bigness with their anti-monopoly suits, but how long has it been since you've read about one of those? They did break up AT&T and slowed IBM down for a few years, but these days we're seeing the big get bigger by gobbling up the other big guys as well as bundles of smaller businesses.

I don't have any proposed solutions for this weakness in capitalism, I just wanted to make sure that I have company in worrying about it. Since the giants are essentially running the government, we can't really expect much help from that quarter. And, until we're able to improve our school system, we're not going to have many people with the guts to cooperate to do something from the grass roots.

A recent letter from a reader mentioned that a psychology professor opined that our school system destroys initiative in all but about 5% of the people. That helps explain why I'm up here on my soap box waving my arms in dismay to so few people. Everyone else is hypnotized somewhere watching a ball game. Or at a church supper.

Shortchanged

I've been shortchanged. You've been shortchanged. We've been

lied to, hypnotized, and brainwashed by the media, the school system, and the government... with the result that around 99% of us are taking all the crap that's going on and believing that there isn't anything we can do that will make a difference. Imagine what a country this would be if 250 million people decided to make a difference! Heck, if just a few thousand decided that they were going to actually do something about the mess.

We're taught in school that honesty pays. Well, that's hooey! Another con job. Honesty doesn't pay worth beans. I've had bigger screw jobs than anything you can imagine, and not one was done honestly. Hey, I had a $100 million property stolen and there wasn't one damned thing I could do about it.

Every industry that I've gotten into has turned out to be crooked to the core. I've written about the magazine distribution industry and its crime connections. And about the music industry, also with organized crime connections. Not one industry that I've gotten to know about intimately has turned out to be honest.

Our country is run by crooks. I'm exaggerating? Then you haven't done your homework and read the books on my list of *98 Books You're Crazy if You Don't Read*. I'll bet you haven't even read P.J. O'Rourke's *Parliament of Whores*. If the government was honest there wouldn't be thousands of lobbyists being paid billions of dollars every year to bribe government officials.

You? Hypnotized? Brainwashed? Sure, get angry with me for bringing it up. But, just for a minute, remember the denial alcoholics and other drug abusers are into. Remember that when someone is given post-hypnotic suggestions (orders) they will faithfully carry them out, rationalizing their every action.

If you are commuting to work ...if you are worried about being downsized, outsourced, laid off, fired, then you're in need of a deprogramming intervention. If you don't love what you're doing you've been brainwashed into accepting a sort of slavery. Slavery to big government and big business.

Does it bother you that the first five months of the year you are working for the government? Or is it six now? So what are you getting in return for all that time and work? Hmm, let's see. We get roads to drive our cars on. Of course, unless we pay a stiff tax on our car every year, we can't use it. And the gas we use is taxed too. Indeed, that alone is supposed to be paying for the roads. But that's a state matter, not federal. What is the federal government doing for us?

Well, there's the military. Yep, we gotta have one of those. Well, there goes 5% of the federal budget. We get the services of the FAA, which makes flying safer. Okay. And we get the FCC, which regulates the airwaves. There's some good in that too. And there are our national forests and parks.

Well, how about social security? As Steve Forbes has pointed out, if the feds would let us put aside the same money in private accounts we'd get back almost four times as much as we do now. Well, it costs a lot to support millions of government employees and their generous pension funds. Social security is one hellaceous screw job. It's just another tax where they, in essence, take around $4,000 from a senior every month and give him $1,200 back. Here, let's see you live on that, old-timer.

If you weren't totally brainwashed you'd never in this world send your kids to a public school. And you'd be pretty angry over the poisoned garbage being sold by our supermarkets. I'm exaggerating? I wish I were, but then I haven't been able to get you to do your homework and learn what's actually going on. I'm not asking anyone to believe me, but I am asking that you check out the books I've found that make a lot of sense to me and which will give you a new perspective on things.

So you go along doing things you know you shouldn't and not doing things you know you should, and then when you finally break down your body you go to a doctor. Hmm, headaches, eh? Here's some pain killer. Cancer? Lordy, we've got to pour some industrial-strength poisons into your body and kill that damned cancer. If you ever find a doctor who tries to find out why you have the cancer, please let me know. I don't expect any mail to result from that request.

When you get sick it's because you've done it to yourself. The element of chance is what organ or part of your body is going to crap out first. But you go merrily on, knowing or not knowing how you're lousing up your body. Your "education" did not teach you much about body maintenance, and even less about continuing to learn all through life. So you suck in on a life of Cheers bars, bowling, or watching ball games. Or sitcoms. And commuting to work until a computer or a Pakistani replaces you.

Wayne Disappears!

A call from René, who wrote the book *NASA Mooned America*, which he's self published, reminded me that Bill Kaysing, who wrote *We Never Went To The Moon—America's $30 Billion Dollar Swindle*, is suing one of the astronauts who called him "crazy" for libel. The case comes up in October, so Bill and René are busy organizing exhibits which will back up their contention that all the moon landings were faked.

I get kooky books sent to me all the time, so when René sent me a copy of his book I sighed and expected to read the usual polemic. Well, I've written about my conversion. Since then I've helped René sell hundreds of his books and not one person who's read his NASA book has written to say he thinks René has his facts wrong.

Kaysing, who worked for Rocketdyne during the years when they were developing the engines for the Apollo program, knew that the engines powerful enough for the moon shots had all failed and that the engines they ended up using couldn't possibly provide enough power for the trip. Knowing that the moon shots were impossible, Bill started researching the project, looking for other deceptions... and he found plenty.

Kaysing's book makes some of the same points as René's, but he also has a bunch more. Like the pilot of a commercial airliner flying to Tokyo who reported seeing a high-flying plane drop a command module, which then chuted to the ocean below. Or the recording NASA released of Armstrong and Aldrin talking with Mission Control while descending to the moon. The problem here is simple; a rocket engine developing 10,000 pounds of thrust generates about 140 dB of sound, so voices anywhere near it couldn't possibly be heard. And so on, for a long list of contradictions.

Now, will NASA and the CIA, who apparently worked with NASA to put over this charade, let this come to trial or will Kaysing and René both disappear or inexplicably die... as have several other whistle-blowers? Will they be after me too? I've already had one government agent tell me flat out that if I ever wrote about his agency again he guaranteed I would be put in prison and never get out. No, I haven't written about them again.

The government we have today bears little resemblance to that envisioned by our founding fathers. No, it's not as bad as Russia or China, but we sure could use some housecleaning. And the Senate too.

How could NASA and the CIA pull off a $40 billion swindle like that? Well, you saw the *Apollo 13* movie, right? That was a movie. And maybe you saw *Capricorn One*? Well, rent it, then.

When Kennedy said we'd go to the moon and Congress budgeted for it, NASA was faced with a serious problem when they later discovered that they weren't going to be able to do it. Should they give up years of nice-paying jobs or fake it? Not many people had to know the truth, so there was a good chance of maintaining secrecy.

Since I originally wrote about René's book I've heard from several people who were not at all surprised as a result of their own work on NASA and related projects.

Well, I hope they won't feel it necessary to terminate me—I just have so much more to write and do before termination. And I'm anxious to be around to see if the prophecies for world cataclysm in 2000 and 2012 pan out. Golly, I'd sure hate to miss out on a cataclysm.

The Magic Bullet

While we're healthy we don't give much thought to preventing illness. When we get sick we look for a fast remedy—at least something to get rid of those darned symptoms. The body has an excellent repair system built in, but it can be disabled, allowing all sorts of opportunistic invaders to take hold.

The Bioelectrifier looks like a good approach to helping the body get rid of invaders such as microbes, parasites, yeast infections, viruses, fungi, and so on.

Low Power Operation

Michael Bryce WB8VGE
P.O. Box 508
Massillon OH 44648

Last month, I mentioned I would be presenting a different project. However, this is a project you should not necessarily run out and build. It's more of an experimental project, although it does serve a real purpose in life.

The project

As odd as it sounds, the project is a ten-minute ID timer. As I said, nothing special. Oh, no? What makes this timer different is how it works. But first, some background on the ID timer.

Another project—another circuit

I had been working on a different project and needed a way to produce a pulse every ten minutes or so, and at the end of the pulse, the output had to stay on for a second or two as well.

Normally, when someone needs a circuit for a simple timer such as I described above, an LM555 timer is used. However, in this case, I also needed a two-second pulse at the end of the time period. With two separate time periods, that would require two LM555 timers, or one dual timer, the LM566.

This was not acceptable. I needed a very small parts count for the circuit I was developing, and adding one more chip was not an option. In fact, I did not want to add a single chip to the project. I had one section of an op amp left with which to build a long-duration timer and produce a two-second pulse.

I also required the circuit to reset and start timing again once the long-duration time period was up, so what you see in **Fig. 1** is the result of many hours of daydreaming and lots of paper!

How it works

My one section of an LM358 op amp is the heart of the timer. For clarity, I show this one section only. The other section is used by the rest of the circuit and is not required by the ID timer.

Generate the ten minutes

The Vcc in this ID timer is +8 volts. I used a small 78L08 regulator. It's part of the overall circuit and not shown in this schematic. Vcc is applied to R7 and slowly charges C1. Capacitor C1 is a husky 4700 µF electrolytic capacitor. The time it takes to charge is determined by the Vcc and R7. For this reason, we use the eight-volt regulator to ensure a constant timing period.

The positive input of the LM358 monitors the charge on C1. The negative input of the LM358 compares the charge on C1 to the reference generated by R16 and R17. In effect, they divide the Vcc by half. Again, another reason for the regulated Vcc required for the ID timer.

With the values shown for R7, it takes about 9 minutes for the charge on C1 to match the reference on pin two of the op amp. The R/C time constant makes up the long-term time period of the timer.

When the comparator switches states—it is normally off or low—several things happen.

First, the long-duration timer must be reset. This is accomplished by turning on Q2 via R18.

Now we must also generate the two-second pulse at the same time. To accomplish this feat, I added some rather heavy hysteresis to the op amp. This hysteresis loop consists of R10, D4 and R8. When the op amp switches, this hysteresis loop will offset the voltage of the R7/C1 sample, effectively holding the output of the op amp on slightly longer. However this is still not enough to produce the two-second pulse.

I had to add R9 to slowly discharge C1. The trick was to find a value of R9 to produce the required two seconds while discharging C1 down enough to generate another ten minutes' worth of charging. If you increase the value of R9, you get a longer pulse at the end, but you shorten up the time it takes to recharge C1. Make R9 smaller, and you get a shorter pulse and longer recharge time on C1. With the values I have shown in the schematic, you'll get a two-second pulse about every 9.3 minutes.

You can also change C1. Adding more capacitance will of course make the timer run longer. A smaller value for C1 will reduce the timing cycle. If you don't have one large cap, feel free to use several in parallel.

The output from the op amp can be used to drive an LED or tone generator. I use a solid-state sounder I picked up from a hamfest. Its low current allows it to be driven directly from the LM358's output. If you require higher output switching, you can use a transistor switch as shown in the schematic. Basically, it's just a cheap NPN transistor that's turned on by the output of the LM358. If you decide to use a relay as the high current switch, be sure to add a small diode across the coil's terminal to prevent the EMP pulse from zapping the switching transistor.

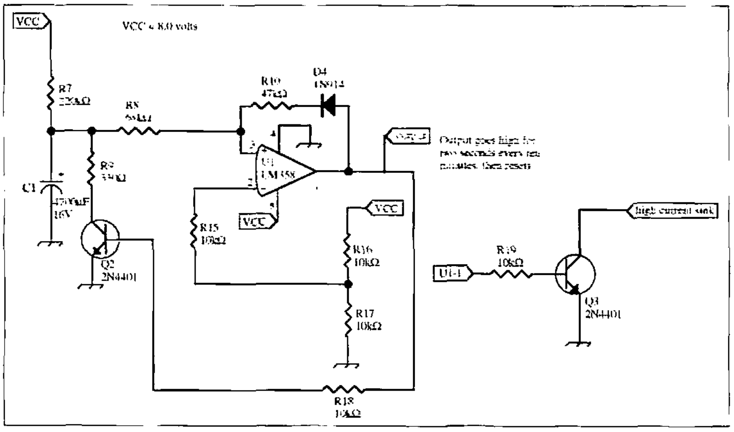

Fig. 1. The low-tech 10-minute timer, shown with the high-current driver option.

Building the IDer

I have no PC board for this project. I figured it would take about as much time to lay out a PC board as to use point-to-point construction. Perfboard would be the first choice for me. I used a prototype solderless setup to test the circuit. If you don't have one of these, I suggest you invest in one.

Keep the Vcc steady; aside from that, you can use +12, +8, or +5 volts for the Vcc. If you change the Vcc from the +8 volts I used, you may have to fudge either or both R7 and R9. There is no need to change out R16 or R17. They will divide the Vcc in half regardless of the Vcc used.

You can save some money by getting C1 with a 16 VDC rating. The Digi-Key price for the cap is about $4 each. I've seen caps that will work from Hosfelt for a quarter a pop!

The entire idea of the ID timer is to use a leftover op amp in one of your projects. You may have one section left over from an audio filter in a direct conversion rig. Here is your chance to wire up an ID timer without adding an extra chip.

Playtime

For goodness' sake, please play with this circuit. It's meant to be changed. Use the basic circuit to start with and change values as you go. If you have a leftover op amp in one of your rigs, go ahead and build in an ID timer!

QRP kits from Ten-Tec

Here's some info on the newest QRP kits from Ten-Tec: The new rigs are designed for 80, 40, 30 and 20 meters. Easy to build and simple to operate, each unit covers a 50-kHz segment selected at time of construction. Kit includes all required components and professional enclosure painted and fully silk-screened. Receiver performance is superlative and QSK is just what you expect from the hams at Ten-Tec. I'll have a complete review of this new QRP transceiver from Ten-Tec. Look for it soon. Next month, I'll have some ideas for running our low power rigs on batteries in the field, and other interesting stuff.

PROPAGATION

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

May is expected to be a rather bland month for DX propagation because of the approaching summer solstice, although there may be some days of high sporadic E propagation. Look for prime conditions (G) between 1-4, 9-17, and the 31st. Look for only fair (F) conditions 6-7, 19-21, 25, and 29th. The remainder will be trending. I don't foresee any major ionospheric or magnetic field upsets or any major geophysical problems this month. At the time of preparing this forecast (February), the solar flux remains at a disappointing low value of between 70 and 75, with no apparent upswing yet in sight. Sunspot numbers continue low, and the sun is very quiet. Considering this prolonged minimum, I suspect cycle 23 will be off to a slow start and a low peak of 150-200 flux units sometime around the year 2003. Most observers consider an average solar cycle to be around 11.2 years, but there seems to be mounting evidence that the *true* cycle is closer to 23 years on average—with two peaks and three minima—similar to a sine wave, if you want to visualize it. I fervently hope this rather gloomy forecast is wrong, but we'll have to wait and see, won't we?

10-12 meters

You may expect occasional short-skip openings from about 500 to 1500 miles. There may be rare openings to greater distances, but not regularly.

15-17 meters

You can expect some reasonable short-skip propagation out to 1500 miles or so, and occasionally greater distances, particularly transequatorial DX skip—with sometimes surprising signal strengths.

20-30 meters

As almost always, 20 meters will be your best DX band for both daytime and evening periods. Twenty will stay open until well after dark, and thirty really begins to shine in the late evening hours. Peak conditions exist shortly after sunrise at your location, and again in the late afternoon. Midday conditions are not likely to be good due to excessive ionization and absorption. Short skip will be excellent out to about 2500 miles on both bands on the best days.

40-80 meters

Forty will be excellent after dark unless the noise levels from thunderstorm activity are excessive. These will be "all-night" bands, with 40 slightly better than 30, except for noise. Daytime short skip will average 1000 miles or more and nighttime short skip will average 1500 miles or more—usually more.

80-160 meters

These two bands are not known for summertime DX, and May is close enough to summer to be a problem because of high noise (QRN) levels. However, on quiet evenings you may find superb DX across the Atlantic on 80 meters for US and European hams. One-sixty is always a summertime problem, but those of you with Beverage antennas for receiving and vertical antennas for transmitting will do better than average.

Gray-line DX

Always be aware that a half hour before and after local sunset often provides some really fine DX along the paths of darkness on all bands. *Use it* to your advantage. W1XU. 73

NEVER SAY DIE

Continued from page 65

But these beasties wouldn't likely have established a beachhead if the immune system was working well, so getting rid of them is only going to be temporary unless you make some changes.

The Bioelectrifier, or Beck Blood Purifier, was originally developed as a way to fight the AIDS scourge. But the alternative health care field is no more honest than our medical-pharmaceutical-insurance-FDA-NIH-etc. monopoly, so who knows what to believe? There are crooks and hucksters at every turn. The medical (etc.) industry has the government behind it because that's where the big money is. The doctors' organizations, nurses, hospitals, drug and insurance companies (etc.) all have well-heeled lobbyists with bribe money to invest in our politicians to make sure their companies prevail.

Now that there's no question but that vitamins help keep us healthy, the doctors via their lobbyists and their kept politicians are pushing the FDA to make sure that doctors get a piece of the vitamin action by making them available by prescription only.

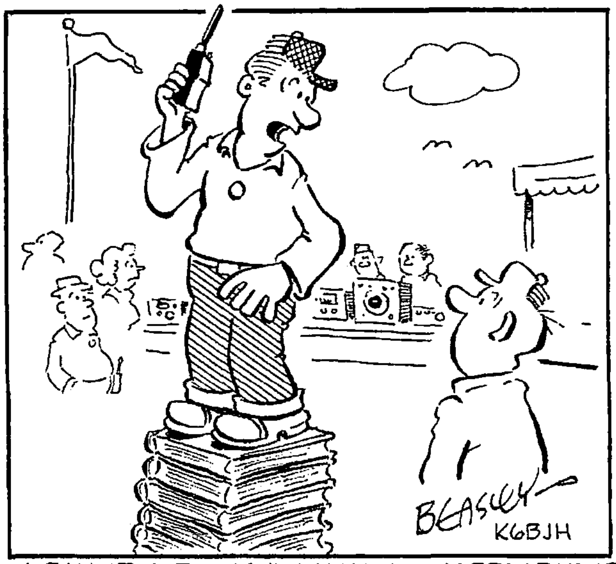
Now, getting back to staying healthy. There are two major factors which combine to make us sick. One is the lousy treatment we give our bodies and the other is stress—the psychological factors. A long time ago I reviewed a book, *Who Gets Sick*, by Dr. Blair Justice. I'll have to add that to my list of books you're crazy if you don't read. Blair makes an airtight case for the triggering effect of psychological problems. Almost 50 years ago, when Hubbard proposed this concept in his book, *Dianetics*, it was ridiculed by the medical establishment. Germs make people sick, not bad thoughts. Doctors have gradually come to accept the idea, but (as I've mentioned a few dozen times) none of them that I've ever heard of is doing one darned thing about it. They're busy treating symptoms with chemicals and knives, and to hell with the actual causes of the illnesses.

You gotta have both germs and bad thoughts. And a weak immune system.

So, sure, the Bioelectrifier may be able to work some temporary miracles, but in the long term you'd better start cleaning up your act, with both good nutrients and good thoughts.

A reader, whose father managed to blind himself by staring into the sun, was aghast over my mentioning the importance of getting UVs into your eyeballs. Hey, I keep asking you to get my review of the books you really need to read, and one of them, by Dr. William Douglass, explains in detail about UV-ing your eyes and the sicknesses that ensue when you don't. Which most of us don't. We keep windows in our homes and cars between the sun and our eyes. And then, when we go out, we wear sunglasses. I haven't worn sunglasses since reading the book. Read the book! And no, I'm not recommending anyone stare directly into the sun. But you can cast your eyes into the sky near the sun so it can get into them without frying them. It only takes a few minutes a day.

Read the books on water, our missing minerals, on a raw food diet, and so on. Either educate yourself and start avoiding things which will make you sick (no matter how good they taste), or suffer the consequences, turning to your doctor to try and effect repairs. Whoo, is *that* an expensive and painful way to go! 73



I FOUND A BOOK ON HOW TO INCREASE YOUR HANDHELD RANGE--- I BOUGHT A DOZEN COPIES, BUT MY RANGE IS ABOUT THE SAME

HAM RADIO FUN SECTION

On the cover: Conard Murray WS4S captured Jeff Gold AC4HF mountaintopping with his LDG Auto Tuner. Both are from Cookeviile TN. Next month: YOUR cover shot? Submissions gladly welcomed. Why not make a little extra cash?

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107. The entire contents ©1997 by 73 Magazine. No part of this publication may be reproduced without written permission of the publisher, which is not all that difficult to get. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateur Radio Today*, 70 N202, Peterborough NH 03458-1107. 73 Amateur Radio Today is owned by Shabromat Way Ltd. of Hancock NH.

Contract: By being so nosey as to read this fine print, you have just entered into a binding agreement with *73 Amateur Radio Today*. You are hereby obligated to do something nice for a ham friend—buy him a subscription to *73*. What? All of your ham friends are already subscribers? Donate a subscription to your local school library!

Bio News

Have you built a bioelectrifier (May 1996. May 1997 *73*) so your doctor can check out its potential for eliminating viruses. yeasts. microbes. fungi. and parasites from the blood of his patients yet? I've been getting some enthusiastic letters from readers reporting remarkable results: "More black hairs on my head—teeth and gums improved—improved vision—improved elimination regularity—it seems like every day I discover something that works better, what a miracle!"

Well, you can lead a horse to water. Through my book reviews (etc.) I've pointed out how you can add at least another 20-30 years to your life expectancy. Years of robust health, not doddering around a retirement home, awaiting the inevitable heart attack, cancer or stroke. But getting you to change your lifestyle by taking advantage of this information is totally beyond me.

Yes, you want me to write about amateur radio. And hamming is fun. It's a lot more fun when you are 100% healthy. And it's a lot more fun when you take advantage of the adventure the hobby provides. It may be putting up a 500-foot antenna via a kite or balloon, or lofting a little ATV camera via a balloon. Or maybe a little long weekend trip to St. Pierre (FP8) for a mini-DXpedition. Or getting together with a half dozen other adventurers for a few days on Navassa (KP1), fielding the humongous pileups.

Yes, of course I'm frustrated at your insisting on commuting to work every day instead of having your own business. You obviously haven't read Danko's *The Millionaire Next Door*. Or my book, *Making Money*. A little over 1% of Americans are millionaires, so is it really all that difficult for you to imagine being more successful than 99 of your friends? It doesn't take much more effort, only a redirecting of your life—out of the rut the other 99 are in. And, in the case of healthy living, out of the rut 99.999% of the others are in. You only have to look in the market baskets at the supermarket and then at the pushers to see the correlation between the food they're buying and how healthy they don't look.

In the short run it does seem as though the bioelectrifier can work some miracles. In the long run it's your mouth that will work more health miracles, and your understanding of the secret of making money that will determine whether you have any real freedom or not. I hope you'll opt for change so that in a couple of years you'll be asking me to go along on a DXpedition with you to Minerva Reef or some other weird place. I'll bring a rig and my scuba gear and we'll have a ball! But if you're going to climb that ladder up the cliff at Navassa, you're going to need all the energy you can muster. It's a corker.

Pirating

I was talking with John Ramsey of Ramsey Electronics the other day and I asked him which of his kits was his best seller. He said it was his FM transmitter kit. It seems that my preaching about entrepreneur-ialism hasn't fallen totally on numbed ears and school-system de-motivated psyches. More and more hams are going into business for themselves selling, installing, and servicing low powered FM transmitters. The applications? They're only limited by their imaginations.

Some businesses and hospitals use them for distributing music. Some use them for paging systems. Others set them up with a cassette recorder, CD player and a mixing board as a pirate broadcasting station serving their community. No, the FCC is not delighted about this, but unless there are a bunch of complaints, not much seems to happen. And then, they issue a warning before sending in the swat team to confiscate everything in sight and levy a fine or impose a prison stay.

These low powered rigs don't cause much trouble, though now and then some enterprising pirates can't help setting up an outside antenna and adding a pair of shoes. Yes, Ramsey sells a beaut of a 30-watt amplifier which absolutely, positively should not be used for pirating.

Some hams are getting real estate agents to set up the FM rigs in houses they have for sale, using an endless loop tape telling about the property. Prospects have merely to tune their car stereo to the channel and get the sales story when they visit the properties recommended by the realtor.

Now get those little gray cells out of neutral, where they've been idling for the last few years, and come up with more uses for these li'l dyn-o-mite gadgets.

Golly, what a great pirate station I could run! I've got a killer collection of CDs for music, and an endless bunch of things to talk about. Ask anyone who's heard me at Dayton. What I don't have is the time to do something fun like that. Also, while the FCC may find it merely annoying when they get complaints about a pirate FM station, if the guy running it turns out to be a ham, he'll probably lose his ticket. Sell 'em, install 'em, service 'em, but don't operate 'em if they're going to cover more than is permitted for low powered unlicensed devices.

FCC Swat Teams

One part of the new Communications Act that Congress passed last year was a sleeper called the "Communications Decency Act." This beaut provides criminal sanctions (a.k.a. prison) if a minor is exposed to "indecent" or "patently offensive" material via telecommunications, and that includes amateur radio as well as the Internet—and even Howard Stern. A lot of fuddy-duddy groups are upset over this—like the ACLU.

Of course there's no way to define "patently offensive," so this will be great meat for lawyers. Well, they don't have nearly enough to do, as we can see from the endless law firm ads on TV begging us to let them sue someone for us and get all that money we're rightly due.

If the FCC swat teams start monitoring 75m there are several infamous nets which will keep them busy. Well, I've given up waiting for our only national organization (which I won't identify here for fear of being accused falsely of ARRL-bashing) to take some shreds of responsibility in this area, but they don't seem to give a hoot what awful things are going on in our ham bands.

I'll have to get a copy of the law and see if the swat teams can confiscate not only the radio equipment being used to create this poisoning of minor minds, but maybe they can confiscate the house and other property too, like they do when someone merely alleges that drugs are on the premises.

Hey, maybe our ham clubs can form vigilante teams to make citizens' arrests of foul-mouthed hams. We should look into that, eh? But let's get busy on this before some well-meaning do-gooders spoil everything by getting the law rescinded.

Positive Action

Here's what the ARRL should have done instead of blustering: They should have used a positive approach instead of a negative one in dealing with the LEO ogre. John Keating WA2FVL has the right idea. He's written to his congressman explaining what is going on. The result was that a Representative who'd voted to sell frequencies now has had a change of heart. Congressmen are dealing with endless bills, many of which they know little about, or have been pressured on by lobbyists. Like the general public, they know almost nothing about amateur radio—much less that there are some agitated voters in their district with a special interest in preserving our frequencies.

Instead of calling the LEO people names we should spend our efforts educating the people who are going to make the bottom line decision: Congress.

Conspiracy

Dagnab it, while I'm suspicious of most of these conspiracy theories that readers write to me about, there is one where capitalism is again biting us where it hurts. The multinational pharmaceutical giants are not just writing the American laws for us to favor their products, now they're at work on a global basis. Well, when you're making the kind of profits they are, why should they think small? Why not influence the UN, the World Health Organization, the FDA, NIH, and other assorted havens for tenured bureaucrats shuffling papers until their pensions kick in?

Not only are these giants in almost total control of our American medical industry, but also the European.

So what are they plotting now? They want to close down the alternative health industry, which is made up of small companies, and thus is vulnerable to giant lobbying power. And that includes vitamins and food supplements, unless they are prescribed by a doctor. Well, that ought to quadruple their cost. Or worse.

Yes, I know that the alternative health industry is in one heck of a mess. They're not allowed to promise health benefits, and the medical industry refuses to test their products, so the public has no way to know what works for what and what doesn't.

I get audio tapes, videos, books and direct mail promotions for endless nostrums. If I got sucked in on all this stuff I'd be spending hundreds of dollars a week and doing who knows what to my body.

Yet, when I read a couple of the medical newsletters that I've come to trust (such as *Second Opinion)* by Douglass (who does not answer his damned mail), I find him extolling the virtues of essiac for people who've misnourished themselves into cancer. Well, the book on essiac is on my list of books you're crazy if you don't read, so I'm pleased to see my opinion confirmed.

Unless you make a fuss over this with your representatives in Congress you're going to get screwed. Again.

CC&R

Read the fine print! If you are moving into any kind of a community you'd better look carefully before you sign that contract. Look for the Covenants, Conditions and Restrictions. And in them, more often than not, you'll find that you are not permitted to put up any kind of an outside antenna.

Talk about ham emasculation! A true-blue ham would prefer a tarpaper shack out in the country to a showpiece house where no antennas are permitted. We hams live and die by our antennas. After all, what's more important, impressing some people (non hams, of course) with how much money you were able to spend on a house, or to have a hellaceous signal? No contest.

Before you move make damned sure you can put up any kind of a tower you want—that you can swing a 40m beam from it if you feel like it. I've always been a 20m person myself. Besides, a 32-foot beam is a lot easier to put up than a 64-foot monster.

Any real ham wouldn't move into a community anyway. That means TVI, angry neighbors, and aggravation. My nearest neighbor is over a half mile away, and I like that just fine.

If you're stuck because of your job in a city or a crowded suburb, isn't it about time to start planning ahead for that ideal QTH? When you're working for someone else you are never going to be really free. Lincoln freed the slaves, but our school system hasn't. It's planned to condition you to shut up, get a job, and work your ass off until you can retire on social security. Retirement used to include a pension which provided enough money for a camper, but the big companies have figured out that downsizing your job a few years before retirement is cheaper.

Okay, I'm a cynic. In my book on making money I explain that you should only work for other people long enough to learn what you need to know to run your own business. And that's maybe two to five years, if you haven't had your motivation gutted by the "system."

Well, anyway, watch out for those CC&R clauses and avoid any community that has 'em in the contract.

If It Ain't Broke

If you consider the federal deficit, and not even counting trillions of dollars in unfunded future mandatory expenses, our country is broke. Okay, so let's fix it. Are you interested in helping? Hmm, I was afraid of that.

Red-Green

In my editorials and in my review guide to books "you're crazy if you don't read" I've asked the readers to let me know of any really important books I may have missed. After all, I've only been able to read a few thousand books out of the millions of titles published, so I need all the help I can get to sort the wheat from the chaff. And, hoo-boy, there sure is a lot of chaff.

Of course it's the same thing with music, which is why I produced over a hundred of my *Adventures In Music* series of CDs, each with the top-rated track from about 15 independently produced CDs. Since the six major music giants make damned sure that you aren't going to hear independent music by investing over $100 million a year in payoffs to radio station music directors, this seemed like a practical way to circumvent the "system."

Getting back to books, I've been very fortunate so far in having the authors of some outstanding books send me copies of their work. The first that comes to mind is *Vibrations* by Owen Lehto, which is a serious *must* read. The second was René's *NASA Mooned America.* I have to admit that I get a chuckle every time I get an angry letter from a reader over my being taken in by René's claiming that our astronots never really went to the moon. Margaret Chaney W8ONS sent me a copy of her *Red World - Green World.* It's a $12 book (incl. s/h) that can make a major difference in your life. Please note, I did not say "might make a difference." Read this book or else.

Even though I've never led you astray with my book recommendations, you still want to know what the book is about before you risk a whopping $12, right? Oh, ye of little faith. Oh, ye big tightwad.

Okay, okay, here's the story. Margaret says our world is divided into two basic categories—which she labels for convenience as red and green. This holds for people, animals, foods, trees, and even rocks. If you are a "red-world" person and eat "green-world" food you're going to suffer the consequences. And vice versa. Yes, she provides a simple test to determine which world you or any food, etc., is in. It's a test anyone can make any time and it is failure proof. It works every time.

Margaret points out that medications fall into the red-green dichotomy too, so if your doctor prescribes a red-world pill for you and you're a green-world person, that's bad news. She points out that twins invariably are split, with one being red-world and the other green. Why nature (God?) came up with this dichotomy we don't know, and it's amazing that no one has noticed this split before. It sure explains why Sherry and I eat different foods. We've often noticed this. When we go to a buffet restaurant we always end up with completely different foods on our plates. At home she fixes her meals and I

Continued on page 53

LETTERS

From the Ham Shack

Thomas M. Miller WA8YKN, Richmond IN. Bioelectrifier Update: I'm glad so many readers enjoyed my article in the May 1996 issue of *73*. There has been a much greater response than I expected, many wanting circuit boards. This caught me by surprise, since the thrust of the article was on how to make the circuit boards! However, I talked with FAR Circuits at the Dayton Hamvention, and they will be selling boards for the Bioelectrifier. Drop them a line at 18N640 Field Court, Dundee IL 60118, or call them at (847) 836-9148.

I had an interesting experience while playing with different frequencies for the Bioelectrifier. When the frequency was around 100 reversals per minute I noticed that my heart rate increased to match it! I did this twice to make sure that it wasn't a fluke. This may not affect everyone else this way—I get a similar effect from caffeine. After that I limited my experiments to lower frequencies, around three seconds per reversal, which seemed to have a very relaxing effect. I recommend changing Cl and C2 from 4.7 µF to 33 µF or more to get the lower frequency limit down into this range. Another minor change I recommend is the addition of a 33k resistor in series with the +36 volt lead from the top battery in the stack. This will protect the optocouplers in case of an accidental short, and has the additional benefit of providing a maximum current limit for the current adjust pot—so you won't jump if you crank it up too high! Radio Shack sells a switch that mounts on the back of their potentiometers. The part number is 271-1740. If you mount this on the current-adjust pot, it will not only save you from having to make another hole, but will ensure that you always turn it on in the lowest current setting. The "aluminum foil" electrodes make a good low-resistance connection over a large area, making it unnecessary to shave the skin and use messy electrode cream, but I've noticed that after a while they get wrinkled, and the creases make "hot spots" that feel like some small critter is nibbling at your ankles! Also, there is some question of aluminum ions migrating into the blood—not a good thing, to be sure, but highly unlikely due to the polarity reversals and very tiny current. I found a pretty good solution to this. At the auto parts store, I found a roll of two-inch-wide stainless steel tape with a peel-off backing. This tape is much heavier and more resistant to wrinkling than standard foil, and it's already preglued. Also, the stainless steel should eliminate any fears of aluminum ions. I put some on two strips of vinyl and added Velcro for a very comfortable set of cuffs. J.C. Whitney also sells this tape. Call them at (312) 431-6102 and order part number 12DF3575U. Of course, the best (if most expensive) material for electrodes is silver. Large medallions containing one ounce of pure silver are available at coin shops for a small premium over the spot price of silver, and should make super electrodes. Silver is a natural antibiotic, with both antibacterial and anti-viral properties.

I hope you will share your experiences with the Bioelectrifier. Remember, this device is an adjustable micro-current source for personal experimentation, and is not intended as a "medical device," nor do we claim that it is a "cure" for anything. At this point, we have virtually no experimental data, so we don't know what effects, if any, it may have. I liked Wayne's idea about using a bioelectric device as a "plant growth stimulator." In fact, I was interested enough to think up some interesting experiments to try along this line. It would be interesting to see if 50 microamps through the moist soil will enhance seed germination. Are these plants different from those that sprouted normally? Another idea is to modulate the DC current with audio! Experiment with different tones, or play music. A small audio amp and an output transformer would provide a means of modulating the 50 microamp current. It's possible that different types of music could have different effects, although I'd avoid anything that sounds like a cat being turned down in a lathe. As long as we're talking weird, how about this? If we were to reverse the transformer, with the 8 ohm winding in series with the 50 microamps, then run the 1k side to the input of the audio amp, with a lN34 diode in series, we just might listen for sounds *from* the plant! How about listening to one plant while playing music to another one across the room? (Now *that's* weird!) The best thing about this is that (as far as I can tell) the plants have no SWAT teams or big lobbies in Congress, so it might be safe to try these experiments! In fact, I've come up with a slightly different circuit and designed a new board to go with it. It's a lot smaller—so much so that it might be hard for some people to build, but I'm willing to sell an assembled circuit board, fully tested, for $38.00 plus $2.00 for postage. I'll even include a potentiometer with a switch and a small terminal block for connecting the electrodes. You will need a small box and some batteries, available from Radio Shack. This circuit puts out the same DC current and reverses polarity just like the original Bioelectrifier. Although it's called a "Plant Stimulator," there may be many possible uses for this device. What you do with it in your own home is, of course, your own business! I'll be happy to hear about your experimental results with these devices, and I'd like to know about any other uses for them that anyone may come up with.

Beck recommends using a couple small electrodes on one wrist instead of the ankle units he first used. Well, for me that makes it a lot easier. I carry the unit in a jacket pocket and am able to type and work while zzzing myself. I use a couple of Velcro-fastened elastic straps on one wrist. There are two arteries, about an inch apart there. I've written about this before. The lower frequency to induce sleep is an interesting approach which should be explored. And certainly the Schuman 7.8 Hz frequency should be explored. I've tried to get you to read Bird's "The Secret Life of Plants" and "Secrets of the Soil." These explain about the incredible impact of music on plants (a.k.a. crops). And I have a video of a plant hooked up to an oscillator, obviously trying to imitate human speech. Why does classical music help plants grow like crazy (some farmers have loudspeakers in their fields), and rock 'n' roll stunt plant growth? And children's too, I suspect. At least mentally... Wayne.

Guy A. Matzinger KB7PNQ, Cheney WA. From my point of view, the ARRL has once again lost an opportunity to truly be the standard-bearer for amateur radio affairs—when that Board of Directors voted to support retaining the *International Morse Code* Treaty *Obligations*, interpreting the results of one more survey with the usual rationale and explanation for their actions. Any suggestions that the survey is representative of the total amateur population as a whole forget that the League's membership is less than 25% of that population, and that about one-third of those members hold Tech and Tech Plus licenses. Interestingly, less than 12% of their members operate exclusively on HF bands, with most using computers and/or keyboards for code communications. On the other hand, their French counterpart—without "rounding up the usual suspects" and with a refreshing display of truth and honesty—acknowledges that code testing is used to filter and limit participation in the hobby.

The ARRL recently asked for comments on their proposed restructuring of amateur licensing requirements—a proposal that appears to be nothing more than small bits of tinkering. Sifting through the chaff, you discover that the suggested changes are not

significant—mostly window-dressing that continues to promote segregation. However, the restructuring strategy implies that steps need to be taken to contain "perceived" abuses of the handicapped waiver provision—does the League mean to challenge the judgment of the medical profession? The proposal also suggests that there are too many amateurs to allow participation on all bands by *all* operators. Is that comment—considering the remarks of media pundits that: "the ARRL represents the *majority* of *operating* amateurs"—an admission that the *majority* of *operators* are incapable of self-controlling band occupancy?

Amateur clubs throughout the country are lamenting the failure of amateurs to upgrade and new operators to join their organizations. The argument they hear, from young and old, against either upgrading or joining *any* organization is, "the benefits are not worth it." The future of the hobby is at risk unless a way is found to attract new blood and stimulate participation in HF communications. The future of HF bands lies with spectrum use by *all* amateurs—perhaps a period of training using all the bands, with an experienced operator, prior to being issued a license would stimulate interest. We are past the point of upgrading and if a creative solution is not found to energize interest in HF operations then, as the aging old-timers fade away, so will those bands and most of amateur radio.

When an autocratic organization initiates legislation that creates preferential benefits, society becomes divided, and sooner or later, those being dominated by special interests will realize that they are being oppressed by manipulated regulations and collaborating bureaucrats—they will seek relief from that discrimination—usually to the detriment of all concerned. This nation was built on the values and principles of individual responsibility and self-determination, not by people who believe they have the right to control others. Tomorrow's technology must be accommodated—standing pat and limiting participation will almost certainly mean death for the hobby.

James Wilkins, Poolesville MD. Recently there was a local newspaper article about a lost hunting dog who took shelter in a cave containing a bear. They survived by not fighting during the emergency. What caught my attention was that the dog was eventually found because he was wearing a radio collar. It seems to me that ham clubs could gain useful publicity, probably gratitude or even occasional monetary gifts if they could sell simple dog-finders in the frequency ranges of their transmitter hunts. There are a lot of cheap crystal oscillators on the market intended for computer clocks, and the frequency selection is extensive. Lost and hungry dogs in rural areas chasing farmers' livestock get shot, with the full approval of the law. This arrangement also would save dog owners from having to buy both a transmitter and a receiver for $500 or so. Hams need a boost in their public image, as well as an outdoor break from the Internet terminal.

The idea of using a ham skill for the public good, or even—gasp—to make some money seems alien. It probably won't fly... Wayne.

Richard Heppert KC4YQL, Kingston TN. Why a filter? A letter from James Hanlon W8KGI in the March issue of *QST* titled *The Best Filter* described CW as the fairest "filter" to prove one's worthiness to use the HF bands. He describes CW as a "skill that is related to the practice of the

QRX . . .

Tech Support Has Its Moments...

So you think you're computer illiterate? Check out the following excerpts from a *Wall Street Journal* article by Jim Carlton.

1. Compaq is considering changing the command "press any key" because of the flood of calls asking where the "Any" key is.

2. AST technical support had a caller complaining that her mouse was hard to control with the dust cover on. The "dust cover" turned out to be the plastic bag the mouse was packaged in.

3. Another Compaq technician received a call from a man complaining that the system wouldn't read word processing files from his old diskettes. After troubleshooting for magnets and heat failed to diagnose the problem, it was found that the customer had labeled the diskettes and then rolled them into a typewriter to type the labels.

4. Another AST customer was asked to send a copy of her defective diskettes. A few days later a letter arrived from the customer along with Xeroxed copies of the floppies.

5. A Dell technician advised his customer to put his troubled floppy in the drive and close the door. The customer asked the tech to hold on, and was heard putting the phone down, getting up and crossing the room to close the door to his room.

6. Another Dell customer called to say he couldn't get his computer to fax anything. After 40 minutes of troubleshooting, the technician discovered the man was trying to fax a piece of paper by holding it in front of the monitor screen and hitting the "send" key.

7. Another Dell customer needed help setting up a new program, so a Dell tech suggested he go to the local Egghead. "Yeah, I got me a couple of friends," the customer replied. When told "Egghead" was a software store, the man said "Oh, I thought you meant for me to find a couple of geeks."

8. Yet another Dell customer called to complain that his keyboard no longer worked. He cleaned it by filling his tub with soap and water and soaking the keyboard for a day, then removing all the keys and washing them individually.

9. A Dell technician received a call from a customer who was enraged because his computer had told him he was "bad and an invalid". The tech explained that the computer's "bad command" and "invalid" responses shouldn't be taken personally.

10. An exasperated caller to Dell Computer Tech Support couldn't get her new computer to turn on. After ensuring the computer was plugged in, the technician asked her what happened when she pushed the power button. Her response: "I pushed and pushed on the foot pedal and nothing happens." The "foot pedal" turned out to be the computer's mouse.

True story from a Novell NetWire sysop:

Caller: "Hello, is this tech support?"

Tech: "Yes, it is, how may I help you?"

Caller: "The cup holder on my PC is broken and I am within my warranty period. How do I go about getting that fixed?"

Tech: "I'm sorry, but did you say a cup holder?"

Caller: "Yes, it's attached to the front of my computer."

Tech: "Please excuse me if I seem a bit stumped; it's because I am. Did you receive this as part of a promotional, at a trade show? How did you get this cup holder? Does it have any trademark on it?"

Caller: "It came with my computer, I don't know anything about a promotional. It just has a '4X' on it."

At this point, the tech rep had to mute the caller, because he couldn't stand it. The caller had been using the load drawer of the CD-ROM drive as a cup holder and had snapped it off the drive!

Taken from the *Elk County ARA Newsletter*, Vol. 6.3, which may or may not have been the first to borrow it from the *Wall Street Journal.*

Red Cross Calls on DARA for Help

The weekend of March 8th, 1997, the DARA van was dispatched to Cincinnati, Ohio, to assist the Cincinnati Red Cross with damage assessment activities in and around the City of Cincinnati. This callout was due to the worst flooding on the Ohio River in the past 30 years. The initial call came at about 10 a.m. on Friday when Emergency Coordinator Ernie Hudson KI8O notified Van Chairman John Phillips N8ZGT that the van was needed in Cincinnati. Plans were immediately put into action to alert the necessary personnel.

Early Saturday morning the van left the Bellefontaine Road site en route to the Red Cross Chapter in Cincinnati. After a briefing session, the van was deployed to Pendleton County, Kentucky, about 50 miles from Cincinnati. The van set up operations at Pendleton County High School. The van was to pass traffic from the Damage Assessment Teams to the Cincinnati Red Cross Emergency Operations Center. The Red Cross had 60 Damage Assessment Teams in the flooded area. They could not communicate with the EOC due to terrain and limited radio capabilities. The van was able to relay traffic to the EOC without difficulties.

The van and its crew remained in Cincinnati overnight Saturday. On Sunday morning the crew was dispatched to the Red Cross Shelter in Brookville, Kentucky, in Bracken County, farther east from the previous day's location. The Damage Assessment Teams were surveying the area northeast of Brookville, near the city of Milford. Sunday afternoon the van was relocated to Augusta, Kentucky. In Augusta, the van crew repeatedly saw extensive damage from flood waters. There were several structures more than a hundred years old that were heavily damaged by the flood. Several mobile homes were washed off their sites; all that remained was gravel and pipes sticking from the ground. The front porches from the mobile homes were located several blocks from the original sites. Everything was covered with mud and soaked with foul-smelling water. Several of the Damage Assessment Teams reported seeing only the roofs of buildings above the flooded areas.

The van continuously operated on three or four VHF and UHF frequencies, maintaining communications with the Cincinnati EOC and stations in Dayton. The stations in Dayton were prepared to assemble relief operators if the situation warranted. Also several of theDamage Assessment Teams could communicate with stations in Dayton only via the FARA 145.19 MHz repeater system. The van relied on relay traffic from the stations monitoring the 145.19 FARA system.

While the van and its crew were operating on the Kentucky side of the Ohio River, more amateur operators were busy on the Ohio side. Many

amateur operators assisted with the disaster relief operations in Ohio, Kentucky, Indiana, and Illinois.

Here are personal observations from Ron Moorefield W8ILC, D.E.C., and Ernie Hudson KI8O, E.C. Mont. Co.

"This is a summary of the Ohio River Flood and what DARA and the DARA van did on March 8-9.

"The US Weather Bureau said that this was a once-in-a-thousand-year event, especially in areas in southern Ohio and northern Kentucky along the Ohio River.

"When the DARA van was requested to support the American Red Cross Damage Assessment Teams, we saw firsthand what the force of water can do to many small communities.

"We not only supported the Red Cross near Falmouth, Kentucky, Bracken County and Augusta, Kentucky, but offered support to the Kentucky National Guard, Civil Air Patrol, and the Kentucky State Police. It was amazing that the Guard's satellite systems could not see the satellite, so we offered support to them. Also, we had to program the radios for the Civil Air Patrol.

"ARES ID cards are very important and need to be worn. These cards are usually the only thing that will allow you to cross police barriers. If you do not have an ARES ID card, please contact Ron Moorefield W8ILC.

"DARA stations that spent time in Kentucky were: N8XGA, KB8RTD, KC8AVU, W8ILC, N8UFN, KA8GOV, KB8YDS, N8ZGT, KB8PMV, N8JBL, K8QZN, N8HSU, N8TFD, N8UCL, and N3TNQ. Stations that were at the State EOC in Columbus were WD8DLQ and W8RLY. The stations that supported us in Dayton on the FARA 145.19 repeater were: N8VET, N8VVZ, KI8O, KA8OKC, N8VZV, and N8MYQ. Many thanks to the FARA Repeater Group for seeing that the frequency was clear when we needed it.

"The frequencies used in the disaster area were 147.42 simplex, 147.375 repeater to the Cincinnati Red Cross and the 444.9 repeater to the Red Cross as well as the 145.19 repeater for support.

"Again, many thanks for a job well done. The Red Cross indicated that without the amateur communications, the job would have taken a couple of weeks to complete and we did it in two days."

From *RF-Carrier*, monthly publication of the Dayton Amateur Radio Association, April, 1997.

Introducing the Family Radio Service

The FCC created the Family Radio Service back on May 10, 1996, but I've never seen any details about this new unlicensed radio service in *QST*. Why should hams care about a short-range unlicensed radio service closely related to CB radio? Two reasons: (1) over 99% of the people in this country are not licensed radio amateurs and (2) it is illegal to use amateur radio for business communications. Small hand-held transceivers for the Family Radio Service could be used to keep in touch with unlicensed family members or for conversations one couldn't legally conduct via amateur radio. In addition, Family Radio Service transceivers should be relatively cheap, probably about $100.

A total of 14 channels are assigned for the Family Radio Service. These 14 channel frequencies are listed below.

Channel No.	Freq. (MHz)
1	462.5625
2	462.5875
3	462.6125
4	462.6375
5	462.6625
6	462.6875
7	462.7125
8	467.5625
9	467.5875
10	467.6125
11	467.6375
12	467.6625
13	467.6875
14	467.7125

Alert readers will recognize that the first seven frequencies on this list are shared with the General Mobile Radio Service, a licensed radio service that allows a license holder to use up to 5 watts on these seven frequencies, and up to 50 watts on two of eight available repeater frequency pairs. The GMRS repeater frequencies are 12.5 kHz on either side of the frequencies on this list. So why don't people just get a GMRS license instead? Getting a GMRS license involves filling out several pages of FCC forms and paying a $60 license fee.

In an effort to prevent the Family Radio Service users from interfering with GMRS and each other, the FCC imposed fairly tough technical requirements on the transceivers. These technical requirements follow.

Transmitter Power: 0.5 watts ERP
Modulation: FM, 2.5 kHz deviation
Antenna: Integral to unit (no connector)
Frequency Accuracy: 2.5 ppm (0.00025%)

I believe that the first, second, and last items on this list prove that Motorola's lobbyists are smarter than both the FCC lawyers and lobbyists for GMRS interests. Cobra and Uniden America favored somewhat looser standards, but Motorola argued for 2.5 ppm frequency accuracy and 2.5 kHz frequency deviation, standards which require more engineering skill to meet. The reduced frequency deviation and 2.5 ppm frequency stability requirements will tend to keep the Chinese "us too, but cheaper" manufacturers of cordless phones and CB radios out of this market. Motorola also argued for a "tougher" 0.5 watt ERP (effective radiated power) power limit in place of 0.5 watts at the transmitter output to help protect GMRS users from interference. However, considering how inefficient most HT antennas are, I think 0.5 watt ERP is actually a power increase over the 0.5 watt transmitter power the FCC originally proposed.

Anyone wanting more information on the Family Radio Service can go to the source for this article, FCC Docket 96-215. FCC rules for the Family Radio Service are in Part 95.

By George Bednekoff KAØOCN, *PARKing Ticket*, October 1996.

Top 10 Pleasures of Field Day:

10. Fishing bugs out of your coffee cup.

9. Getting lost on the way to the porta-potty.

8. Tripping over guy wires and tent ropes in the dark.

7. Discovering that your three-element wire beam for 40 meters, which took all day Friday to erect, is oriented in the wrong direction.

6. Fixing a broken paddle with duct tape.

5. Finding out what happens to a tribander when you drop it from the top of the tower.

4. Having to choose between Field Day operation and your wedding anniversary.

3. The "food."

2. Explaining to your XYL that the YL ops are "just hams."

And the Number 1 Pleasure of Field Day:

1. Getting in the truck to go home and finding that someone has borrowed your battery.

TNX *The Low Down*, the official journal of the Colorado QRP Society.

Number 10 on your Feedback card

Getting a Taste of VHF

Test drive the bands before you invest in the equipment.

Philip Gebhardt VA3ACK
40 Cameron St.
Ajax ON Canada L1T 2W2
[102515.2604@compuserve.com]

Everyone hesitates to spend a lot of money without first making sure it will be worth it. When you shop for a washer and dryer, you compare features and prices. When you buy a car, you take it for a test drive.

Wouldn't it be nice if you could "test drive" the VHF bands before you invest time and money in the ham radio equipment you'll need to do some serious VHF DXing? That way you could decide if VHF DXing is for you—without making a commitment. You can. Here's how.

The common forms of VHF DX propagation—tropo, sporadic E, meteor scatter and aurora (and F-layer propagation at the peak of the solar cycle)—are not limited to the ham bands. Any VHF signal will be affected by these modes.

And that's what you can capitalize on. Instead of investing money in ham radio equipment to try out these bands, use what you already have. What do you already have on the VHF bands? An FM broadcast receiver and a television set, of course. If you have an outdoor FM/TV antenna, you're in really good shape. A rotor on your antenna is even better—but even without these things, you can get a start on VHF. It's not uncommon to hear VHF DX on an FM car radio.

Many FM (and TV) broadcast stations operate 24 hours a day. Transmitter power is usually in the 25, 50 or 100 kW range. Fortunately, the stations are scattered all over the continent. So, if there's an opening on VHF, you'll hear (and see) these stations.

It's a matter of knowing where and when to listen.

Where?

The "where" part is relatively easy and straightforward. Since the lower VHF TV channels are close to the 6-meter ham band, they are a good choice. (Channel 2 spans the 54 to 60 MHz range; channel 6 occupies 82 to 88 MHz.) Generally, choose the lowest unused channel in your area. If your antenna is rotatable, you may be able to point it away from a semi-local station and create a usable channel.

The FM broadcast band is farther from the 6-meter ham band, but you will still hear the same types of VHF

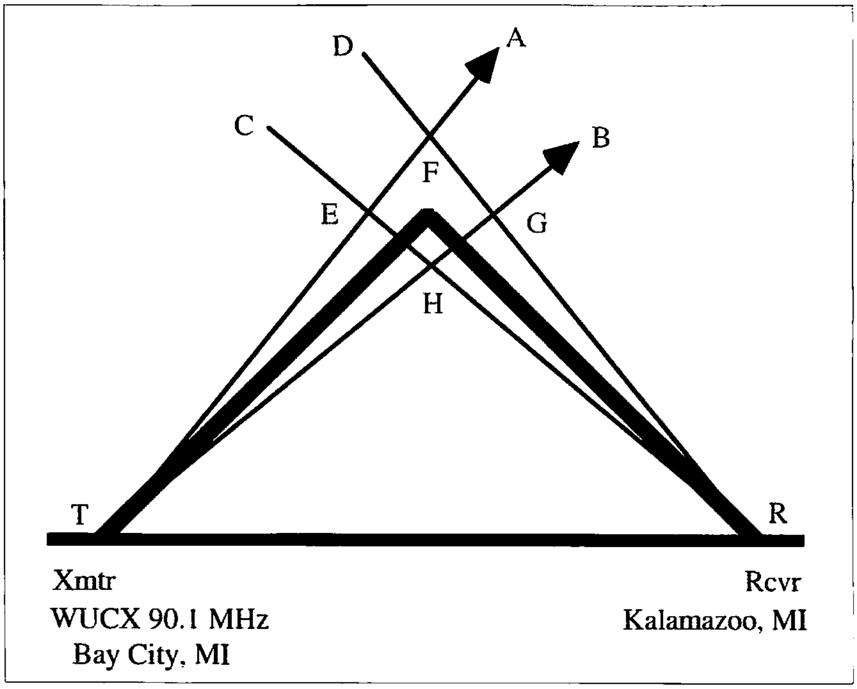

Fig. 1. Reception distance is often increased by tropospheric effects. Scattering from a common area of the sky is only one way this happens. As in other forms of VHF (and HF propagation), the antenna is aimed at the horizon, not pointed upward. The antenna beam is sufficiently large to detect signals coming in at an angle. In this diagram, the width of the beam from the transmitting antenna at WUCX in Bay City is shown by rays TA and TB. The receiving antenna in Kalamazoo "sees" the portion of the sky bounded by line segments RC and RD. The beams of the two antennas overlap in the region EFGH. If there is an anomaly in this region, signal from the FM station will be scattered and returned to Earth. The heavy line shows the path of a signal being scattered and received in Kalamazoo.

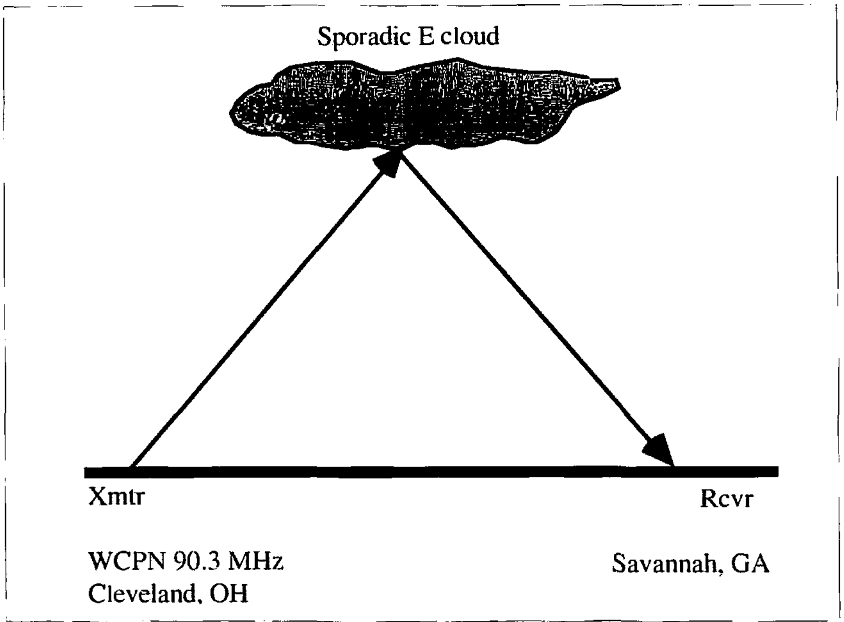

Fig. 2. Signals are reflected by ionized clouds in the E layer of the ionosphere. Sporadic E signals are strong and may last much longer than meteor scatter signals.

propagation. There are plenty of tropo, sporadic E and meteor scatter signals to hear on the FM band.

Choose an unoccupied frequency in the FM band for best results. The lower portion of the FM band is occupied mainly by educational and noncommercial stations. Although they may run lower power than the commercial stations higher up, they may cause you fewer interference problems and you may hear a variety of stations come and go on a single frequency as propagation changes.

You will sometimes hear (or see) DX override a semi-local station or even a local station.

Why an unoccupied frequency? Simply because it is easier to detect weak signals that could easily be masked by a stronger station. Also, it's easier to hear a weak signal if there is nothing but noise competing for your listening attention.

It's easy to select an unoccupied TV channel, but there are several things to keep in mind when selecting an FM frequency. Remember that although the FM band covers the 88 to 108 MHz range, the lowest assigned frequency is 88.1 MHz; the highest frequency is 107.9 MHz. Stations on the FM band are spaced at 200 kHz intervals, so assigned frequencies follow the pattern 88.1, 88.3, 88.5, and so on. There are no stations on frequencies such as 88.2, or 88.25 MHz. A receiver with a digital readout makes it much easier to "park" on an unoccupied frequency. If your receiver has a rule-and-pointer dial, you'll need to estimate the frequency.

If you live in a metropolitan area, finding an unoccupied FM frequency can be a challenge. In that case, the best you may be able to do is to listen on frequencies where signals are weak.

If you are blessed with a QTH where you have a multitude of unoccupied frequencies, you'll need to make a decision about where to listen.

You can use several approaches to solve this "problem" (we all should be so lucky as to have it). You can try the hit-and-miss approach: Just pick an unoccupied frequency and listen.

Another approach is to select your listening frequency based on conditions. (This statement will make more sense after the description later on of different propagation modes.) For this you'll need a reference guide such as *FM Atlas*. This annual publication lists FM stations by frequency and by location. It also indicates transmitter power. Knowing transmitter power allows you to select the higher-power, easier-to-hear stations. Transmitter antenna height (also listed) can sometimes be an advantage to know, too.

That covers the basics of where to listen.

Now for the "when" part

"When" is generally dictated by propagation. Many books go into great detail about the various forms of propagation on the VHF bands. You'll also find some excellent articles by looking through back issues of ham radio periodicals (such as *73*). Here

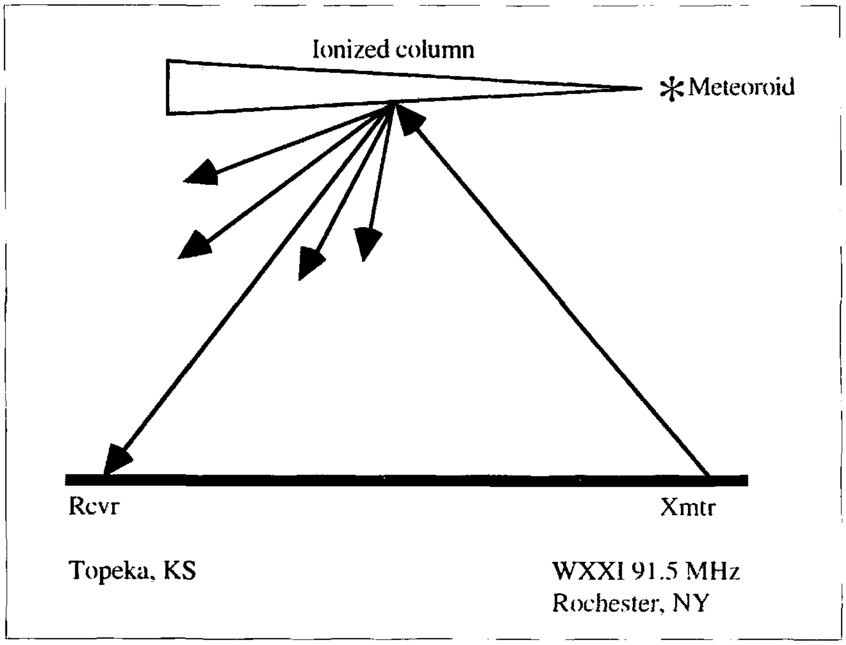

Fig. 3. Signals are reflected by ionized meteor trails. In most cases, however, the signals are scattered rather than reflected in the general sense of the term. The density of the trail governs the reflection vs. scattering effect.

are some basics to give you an idea of when to listen and what you are listening for.

Tropo

There are a number of effects within the troposphere that enhance signal propagation. While the common belief is that signals are limited to line-of-sight range at VHF, this is rarely the case with a beam antenna on a tower. Listen to the FM band and record the stations you hear. It won't take long to realize that many of them are well beyond the line of sight. This in itself is a good lesson in VHF propagation (if you don't know how to calculate the distance to the horizon, check the propagation chapter of the *ARRL Handbook* for the formula).

Stations can be heard almost daily using tropo scatter. Both antennas are aimed at a common area in the troposphere. The lower boundary of the area is determined by the antennas in use; the upper boundary is about 10 km (6 miles) above Earth's surface. That's not very high, so signals are limited to about 500 km (300 miles) between the FM station and your antenna. In practice, the distance is usually much shorter than this.

What makes this form of propagation so appealing is its dependability. There is little day-to-day or seasonal variation. If you live near a large body of water—the Great Lakes, the Atlantic Ocean, the Pacific Ocean or the Gulf of Mexico—you can take advantage of temperature inversions. These occur from the evening until the morning hours.

Weather maps in newspapers, on TV or (these days) available on-line via your computer give clues to propagation. Watch for a warm front approaching your area. Propagation is parallel to the front and occurs for several hundred kilometers ahead of the front. Cold fronts also enhance VHF propagation along the front. In this case, the signals propagate behind the cold front. Start listening just after the front has passed your QTH.

Wave cyclones occur in the spring over mid-America and may provide propagation for a day for stations in the northern, southern, eastern and central states.

Slow-moving high-pressure systems, common in late summer over the eastern half of North America, can provide DX possibilities during the evening and early morning hours. Refer to ARRL publications, such as *The Radio Amateur's Handbook* or *Beyond Line of Sight*, for more details.

As mentioned previously, this is a time when you would want to use an FM station guide to select specific stations to listen for. Why waste time listening on 90.7 MHz during an opening along a warm front, if there are no stations within a few hundred kilometers ahead of the front operating on 90.7 MHz?

Sporadic E

You'll see this form of propagation also referred to as E skip, short skip or Es. The term "sporadic E" comes from the fact that the DX openings are sporadic (and therefore not predictable) and that the ionized clouds responsible for reflecting signals are located in the ionosphere's E layer.

In any case, sporadic E occurs most frequently in May, June and July and to a lesser extent in December and January. Listen from 9:00 a.m. to 12:00 p.m. local time and again from 5:00 p.m. to 8:00 p.m. These are the most common listening times; however, sporadic E can occur at any time of the day or year. The opening may last anywhere from a few minutes to several hours.

Because the clouds form suddenly, signals appear quickly. Signal strength is high. The clouds may also *move* quickly so one strong DX signal may rapidly be replaced by another equally strong signal from a different station.

Because of the increased altitude, sporadic E signals have a greater range than tropo signals. Expect distances from 500 to 2300 km (300 to 1400 miles).

An excellent report on an eleven-year study of sporadic E on the FM band appeared in *QST* (May 1992).

Meteor scatter

Yes, those things you see streaking across the dark night sky affect radio waves. The reason is simple: Not only does a meteoroid produce a visible meteor (trail of light) as it enters Earth's atmosphere, it also produces an ionized column.

This column, like the ionosphere, can reflect signals. How effectively signals are reflected depends on the density of

Shower Name	Peak Date (1997)	Peak Time (UTC)	Duration (in days)	Meteor Rate (per hour)
Eta Aquarids	May 4	2200	6	20
Arietids	June 7	0911	2	60
Perseids	August 12	1800	4.6	100
Orionids	October 22	0100	8	25
Taurids	November 5	0124	30	15
Leonids	November 17	1052	4	15
Geminids	December 14	0600	3	58
Ursids	December 22	1145	2.2	10

Table 1. Data for various showers of interest to amateurs. Each shower lasts for several days, so listen before and after the peak date. The column labeled "Duration" gives an indication of how many days you should listen.

the column. About ninety percent of meteor trails are underdense. Underdense trails tend to scatter the signal, hence the term "meteor scatter."

You can hear meteor scatter any time of the day or night and on any day of the year. There is a diurnal variation with a maximum occurring around 6:00 a.m. local time and a minimum occurring at 6:00 p.m. The ratio of maximum to minimum is about 4 to 1. You may hear a few to a few dozen per hour around 6:00 a.m. This is the pattern for sporadic meteors (meteors produced by meteoroids that travel alone).

Since both the time of arrival and direction of sporadic meteors is unpredictable, you can simply point your antenna south in the morning, select an unoccupied frequency and listen.

At predictable times throughout the year, you can hear an increase in the number of reflected signals. This occurs during meteor showers. Probably the most famous shower is the Perseid shower that occurs in August. During a meteor shower, Earth passes through a large number of meteoroids traveling in highly correlated orbits. Depending on the shower (and your listening setup, of course), you can hear several dozen to several hundred signal reflections per hour. There are even daytime showers that can only be detected by radio means.

"It's a matter of knowing where and when to listen."

Refer to an annual astronomy book (such as Royal Astronomical Society of Canada's *Observer's Handbook*) or a periodical (*Sky & Telescope* and *Astronomy* are available at newsstands) to find the dates for showers. **Table 1** will get you started.

Timing and antenna direction are more critical with showers than with sporadic meteors. You can try the probe method (listening for signals to peak as you rotate the antenna—not very effective in this application), or you can read the VHF manuals for hints. Computer programs are available to calculate peak times and corresponding antenna directions. Check your favorite ham radio BBS or on-line service.

You might think that you need to point your antenna upwards. That is not the case. Point your antenna at the horizon to hear signals reflected by meteors. This approach will yield the greatest distance.

Because meteoroids ablate at an altitude comparable to the E layer of the ionosphere, distances will be comparable to sporadic E signals.

Now, for what you'll hear: Assuming that you are listening on an unoccupied frequency, most of the time you'll hear mainly receiver noise. Periodically, you'll hear a signal rise out of the noise very rapidly. As soon as it peaks, the amplitude will start to decrease. The signal may last for a fraction of a second or for several seconds depending on the meteor. There may also be a residual signal beyond this time.

That's it, folks

No station IDs, no complete songs, no entire weather forecasts. You'll be lucky to hear a few notes of a song or a few syllables (maybe words) of a news report.

Why do people put themselves through this agony? Sporadic meteors are basically practice. The real fun comes during meteor showers because there are so many more meteors. During a shower, you hope for several meteoroids coming into the atmosphere in succession so the signal lasts longer as it reflects off successive meteor trails.

The advent of computers and the use of packet techniques by hams makes signal exchanges much faster (and therefore more successful) than previously possible. So, if you like listening to meteor scatter on the FM band, you'll probably really get excited when you hear it on the ham bands.

Aurora

Signals can also reflect off the aurora. However, the number of opportunities you have to use this form of propagation depends on your latitude. The farther north you are, the more opportunities you get—but it's a little more complicated than that. Auroral propagation depends on geomagnetic latitude. Rather than following those neat lines of latitude that appear on maps, geomagnetic lines slope from

northwest down to southeast. As a result, DXers on the east coast have an advantage.

Auroral propagation is cyclic. There is a seasonal pattern with more opportunities at the equinoxes (March and September). There is also a cycle that may be related to, but not in phase with, the solar cycle. Peaks occur about 2 years before and after the solar cycle maximum. The diurnal pattern indicates two strong peaks—one at about 6:00 p.m. local time and a second around midnight.

Best signals are heard by pointing your antenna in a northerly direction, but probing for the best signal is important.

Predicting auroral conditions on VHF is a matter of listening for the signs on lower frequencies and waiting for the effect to reach the VHF range. Wavering signals that are weak and sound watery on the AM broadcast band up through the 40-meter band in late afternoon or early evening are a sign that auroral conditions are developing. Station WWV broadcasts A and K indices at 18 minutes past the hour; WWVH does the same at 45 minutes past the hour. A K index greater than 5 and an A index greater than 30 indicate that it's time to listen for auroral activity.

Keep in mind that you may not see the aurora, but you may still be able to hear signals via this form of propagation.

This is only the beginning. There are other forms of VHF propagation as well as variations on the ones mentioned here and even combinations, such as auroral E.

If you find that VHF DXing on the FM broadcast band has whetted your appetite, you are a prime candidate for DXing on the VHF ham bands.

By the way, most of the forms of propagation present on VHF also occur on 10 meters. Yes, you can use your HF rig to have sporadic E QSOs; try your hand at meteor scatter work; and make contacts via the aurora. While sporadic E is exploited on this band, meteor scatter and auroral propagation go virtually unnoticed. You will need to pursue these openings with a like-minded ham.

All things considered, DXing on the FM broadcast band (or low VHF channel TV) is an excellent introduction to the world of VHF.

Horsetrading on the Ham Bands

The FCC has approved on-the-air buying, selling and swapping ham gear via the traders' nets.

Ronald Lumachi WB2CQM
73 Bay 26th Street
Brooklyn NY 11214
E-mail: WB2CQM@Juno.Com

Only a short while back it was really a pain to advertise amateur radio gear for sale or to draft the text of an advertisement for an item that you wanted. You had to write the ad, send it along to your favorite media source, and then wait weeks (sometimes months) before it finally arrived in print. By that time, the event was somewhat anticlimactic—often if an individual did call in response to your advertisement, you'd have to be reminded about the details. Hams, being an impatient (but most resourceful and proactive) lot, recognized the shortcomings of this process and began meeting in their on-the-air cliques to discuss what they wanted to buy, sell, or swap. Increasingly popular, these informal groups evolved into more structured, regularly scheduled occasions, attracting larger and larger numbers of participants. Although the nets sport a variety of names, including Horse Traders, Old Gear & Junk, Collins Net, etc., they all afford the radio amateur the opportunity to offer his/her wares on the air, without delay, to a large number of knowledgeable, attentive, and motivated buyers and sellers—and the best thing about it is that the free service is instantaneous. If it sounds like a good deal, it is. Its success can be traced to the tireless efforts of the radio amateurs who are the net controllers. Their unselfish dedication and perseverance make the service possible.

How does the net work?

The organizational rules are simple and straightforward and are generally applicable to any of the traders' groups. Usually when the net is called, the controller briefly reviews the regulations governing its operation. The FCC has allowed hams to advertise over the air provided they meet minimum criteria. [See Part 97.113 (a) (2) of the Regulations for prohibitions and exceptions to the sale/trade rule.] Obviously, the controllers are in the best position to enforce the regulations to the letter of the law since the FCC, because of its manpower and budget shortfalls, has of necessity directed its attention to more pressing matters.

The first and most important admonition is that commercial advertisers are not welcomed. In addition, anyone who has been identified and proven to be (to the satisfaction of the controller) a full-time purveyor of radio gear is told he/she is in the wrong place and asked politely to move on. Third party listings are not permitted but their wants are OK. Any equipment offered must be in the seller's possession. This situation arises frequently when there is an estate sale and a ham, as a special favor to the widow, offers to liquidate the gear. If that's the case, it's easy to conform to both the spirit and letter of the law: Have the gear in the shack when advertising. Net controllers are aware that FCC regulations allow on-the-air sale or trade of any equipment provided it is ham-radio-related. They make a conscientious effort to conform closely to that ruling. To illustrate this point, I recall in one instance an individual offered an aviation-type GPS (satellite positioning) unit and an altimeter, ostensibly to locate and accurately measure the height of one's QTH. He was politely reminded that offering that equipment was stretching the rule a bit too far and was politely directed to hit the road! Computers are accepted on the general equipment nets provided they support some aspect of packet operation. Oddly enough, scanners can be listed with impunity.

A seller may quote a price for an item, but any negotiations, haggling, or plain horsetrading must be accomplished over the telephone. On many occasions, the seller may be asked by someone (through the controller by signaling with the word "contact" and being recognized) to clarify the listing with additional details that may have been omitted. For example, before placing a long distance telephone call, an individual may want to know the serial number of the rig, the number of filters in a particular receiver, or whether the linear is a two-holer or capable of tuning 160m. It's the seller's option to include or omit the asking price. He may prefer to discuss the details more privately over the telephone. One experienced trader mentioned to me that he never calls when a price is not listed. He claims they are invariably too high. If you think it's a worthwhile deal or you need more specific information, make the call. It's important to remember that the nets are "directed," so all inquiries must be channeled through the net controller. Imagine the resulting chaos if it weren't handled in this manner. The controller's task is difficult, to say the least, and virtually impossible to undertake without a first-class radio station, a high degree of personal fortitude, the patience of a saint, and the endurance of a marathon runner. The majority of net controllers maintain a running log of those checking in, including telephone numbers and equipment offered. Some, less technological than others, use their own special

shorthand and keep paper notebooks to record the entries. Others use computers and maintain databases from week to week. Net controllers are routinely asked to search out a previous listing (usually with success) based on very sketchy information. They do it gladly and pride themselves on the sophistication of their logging systems. Most frequently, telephone numbers are incorrectly copied by prospective purchasers (QRM, QRN, QSB) and when queried the controller has the capability to check back into the log and set the record straight. It's not an easy task by any stretch of the imagination, especially when 100+ hams check in with 400–500 bits of discrete information.

How do you participate?

Check the accompanying listing for the net time and frequency that offers you the most consistent propagation. Bands are often noisy and crowded, so listen to those groups that produce the best signal strength to your locale. Interference is often generated in unusual ways. For example, (although it's difficult to explain the motivation) there are occasional incidents of malicious interference from QRMers whose sole purpose is to disrupt the net. Controllers continually remind net participants that they should not get bent out of shape and feed into those guys by acknowledging their presence with speculations about their mental health or family lineage. Past experiences have shown that this passive response works well since those interfering usually get tired and simply fade away. To a lesser extent, overzealous contesters must be continually directed away from the frequency; they usually respond with a quick apology to the controller and an immediate QSY.

Most nets begin promptly and follow a sign-in protocol. Generally, the net controller will accept the suffix of your call in alphabetical order usually beginning with "A." For example, in my instance, I would sign in when the "C"s are called with "CQM." If the controller copied my signal he would acknowledge that I was on the list; if not, I'd try again. If my signal were marginal due to poor propagation to the controller's QTH, I'd ask for a relay. Someone would hear my request and offer to forward the message. Incidentally, mobiles get first

crack at listings. Remember the cardinal rule—*You've got to be on the list to participate!* The hams with the suffix "A" are not always the first to go. Controllers reverse the alphabetical listings weekly. If "A"s were first last week, they're last the next time around. It's the amateur with a callsign in the center of the alphabet who never gets to the head of the line, but there are seldom complaints from anyone. Imagine the confusion if you started at the middle of the alphabet and worked in both directions. On many occasions, the controllers, prior to taking the regular listing, will liven up the sign-in period by calling for a pileup and listening for the loudest station. It's truly organized chaos, but if your callsign is recognized above the cacophony of signals, it's quite an ego trip for the participant. I'll wager there aren't too many hams around who don't want the world to know that they're top banana. It's good fun and enjoyed by all. As a reward for the outstanding five or six of the best signals, the big guns are allowed to list first. It's a small enough compensation for tweaking that antenna, cranking up (sometimes a little above the legal limit) the amplifier, and consuming a bit more electricity. It's an interesting side note but many of the big boys with giant signals accept the accolades and then politely pass on the option to list. They just revel in the recognition and ego-boosting action.

In many cases, the net controller can gauge the length of the net by the number of check-ins. If the list of participants is overly long, it may be decided to limit each trader to a specific number of items. Usually it's never less than four (any combination of buy/sells). If the list appears to be shorter than usual, he may announce that time will be allotted at the completion of the net for latecomers. Pay particular attention for that announcement in the event you arrived too late and the controller has passed you in the alphabet. You'll only get one shot at logging on.

For a variety of reasons, it's a good idea to listen closely to the net rather than become preoccupied at the other end of the house. First and foremost, you won't miss your turn. While listening, you may locate a particular item being offered that is of interest to you. This is especially true if you planned to list a "want" and the item fortuitously appears. More importantly, when you're focused on the listings, you begin to get a feel for the going price of a particular piece of gear. Remember that the "educated" ham will neither pay too much nor ask too little for equipment, provided he/she has done the homework. If you listen for only a short time, you're certain to get the rhythm of the net.

When your turn comes, sign on with your full callsign, handle, and referenced location if you do not live in a city with a recognizable name. In my instance, Greentown (my second station) would have little impact on anyone (except a local amateur, the deer, and perhaps the resident chipmunk) until I indicated that it is situated in northeast Pennsylvania, 20 miles east of Scranton. Because of the high profile of the Big Apple, there should be no problem of location if I'm listing from my (primary) New York City QTH.

"A full-time purveyor of radio gear is told he is in the wrong place and asked politely to move on."

State the items you have for sale (or announce your needs) and be as comprehensive and honest as you can be with this description. Generally, the 1–10 scale is used to evoke an image of condition. For example, a 9+ with a minor scratch on the top cover would indicate that it's close to factory condition but has a surface blemish. Make certain to include all accessory items that will affect the price. For example, what is the serial number? Are there extra crystal filters for the receiver? Do you have the original manual and shipping cartons? Does it include the power supply? Is there an auto antenna tuner? Is there full output on the linear? Are there any spares? Will you ship the item, and does the price include shipping? Does the speaker have a built-in phone patch? Or, with heavy items, would you travel a reasonable distance to meet someone?

Don't be reluctant to advertise a junker, but make certain that you clearly identify what you're offering. Many hams need discrete parts for a restoration or rebuilding project, and what you offer may fit their needs perfectly. To ensure that you've made your list both complete and comprehensible, write down the text of the ad beforehand. Don't try to ad lib. You'll either stumble along and embarrass yourself or leave out a vital part of your message. You'll kick yourself afterwards when you realize why the telephone hasn't rung. It happens all the time, even to the most confident trader. You may, if you wish, state an asking price and indicate if you are amenable to trading for a specific item. If you feel that the trades are not of comparable value, don't hesitate to mention that you are aware of the price difference and willing to offer (or take) an appropriate amount of cash to smooth out any rough spots.

Make a conscientious effort to avoid extraneous comments. Stay focused and leave the chit-chat for another time. Sellers make this mistake all the time. It takes up valuable net time, obscures the message, and generally confuses everyone. Above all, avoid trying to hustle the group by overpricing. Rest assured, the traders know what an item is worth and they don't want to pay for your emotional attachment. You'll know exactly what I mean when you hear a symphony of polite whistles in response to an unrealistic asking price. If that happens to you, you're usually dead meat! Keep to your script and sign out by listing your telephone number twice (slowly) along with the area code, repeating your name phonetically, and listing your callsign. At this point you may offer your E-mail address to those who would prefer to contact you that way.

If you've struck a chord with someone in the listening audience (a hot item at the fair price), expect a telephone call even before you sign off with the net controller. Be prepared for bargaining, but if you've done your homework you're aware of fair value. Feel free to be firm on the price and to reject any unrealistic offer. On the other hand, remember that everyone loves a bargain, so if you're close in price, consider compromising a bit and making the deal. If there's no meeting of the minds, take the caller's telephone number in the event you later

determine that the offer at hand is the best (or only) one received. It's amazing how much better an offer looks when no one else calls. If you've struck a deal, then serious talk should begin. I'd suggest you ask for payment in the form of a postal money order or send the items COD and specify payment to be made in cash. This will eliminate any surprises down the road. It's common practice and not a disagreeable or expensive method to close a deal. Don't forget to jot down the name of the person, callsign, and the telephone number. You may find it necessary to contact that individual at a later date.

If it sounds like a done deal, look for shipping cartons (liquor stores are a good source) and some good packing material during that period when the check is in transit. It's always a good idea to double-pack the component using two containers. Shipping companies are notorious for damaging equipment, so you've got to make it as difficult as possible for them to destroy your treasure. If you are thinking about shipping used equipment with Uncle Sam, keep in mind that the post office usually does not pay off on insurance claims without a battle. Get back on the net to announce your deal as soon as you hang up the phone. Many controllers encourage "rechecks" from sellers to announce that a sale has been made. They will delete the sold item from their computer or simply cross it off. A recheck can also mean someone saves a long distance call. However, if you do happen to get that extra inquiry, take the name and number for reference. On occasion, the money simply never materializes and the buyer doesn't have the courtesy to telephone about the change of heart—so don't hesitate to call the second interested party and make your deal.

What's it worth?

If you haven't spent too much time on the net, it's sometimes difficult to determine what to charge (or what to pay) for a piece of gear. Listen around a bit and hear what's being offered, at what price, or contact one of the controllers prior to the net and ask the going rate for a particular item. Their response, based on experience, is usually on target with prices. If the item you're offering is current production and in mint condition, figure on about 50–60% of the manufacturer's list price as a good starting point. Prices must be adjusted downward if it has flaws and is not up to factory specs. All bets are off if it's an antique and in high demand. Just try to buy a set of original CW and AM filters or a speaker for a Collins 75A4! These discrete components, available a short time back for peanuts, now cost almost as much as the receiver itself. In any event, you'll want the best deal you can get, so if you're not certain, check around. Ask around both before and after the net for the information you need. For many of the regulars, the trader's group is also a social event and they're found around the net frequency with their cronies sharing trading experiences and prices. Don't be reluctant to ask one about the value of a piece of equipment, since most hams are more than anxious to share their expertise.

"Listen around a bit and hear what's being offered at what price."

What's the downside?

Dealing at arm's length (not eyeball-to-eyeball) for an expensive item may be a nightmare waiting to happen. Net controllers are quick to remind participants that they are *not* responsible in any way for the transactions that take place on the net. As part of their disclaimer, they suggest that the involved parties attempt to resolve any dissatisfaction resulting from a sour deal. (You can see the importance of having a clear and written understanding of the transaction details should an item prove not to be to your expectations.) Generally, refunds are made by the seller with no questions asked.

For example, I recently purchased three Collins A4 mechanical filters for a newly-acquired receiver which was at that time away for extensive surgery courtesy of Howard W3HM. The deal was that the money would be refunded if the filters did not work. Four months later, the receiver was returned (with the front end sensitivity hotter than a firecracker); the filters were tested, and one didn't work. I sent a note to the seller in Pittsburgh and within a couple of days

received a refund. How's that for honesty and integrity and a tribute to the net participants?

Although problems are few and far between, situations do arise that require third-party intervention. In some instances, where the buyer and seller are at an impasse, the controller may intervene, determine the facts, and suggest a solution. On extremely rare occasions, there have been alleged instances of outright fraud and misrepresentation. If that's the case, take your postal money order receipt, canceled envelopes with all pertinent correspondence and visit the local postmaster. State your case, present the evidence, and learn whether the mails were used to defraud. Sometimes, a visit or call from the postal authorities can move mountains. If you've successfully identified an individual as a villain, get back to the net controller as quickly as possible with the details. That information will be put into the computer and a general announcement made to the net participants. In addition, the scoundrel may be denied further net privileges until the incident is resolved. It's a powerful and persuasive tool and I can assure you the word gets around, since most horsetraders have excellent memories and frequent many of the nets.

It never ceases to amaze me how few complaints are reported to the controllers as a result of a bad deal. This is certainly a tribute to the amateur radio fraternity and its generally high-principled individuals. This particular group loves to trade and they relish the art of the deal—they are careful to describe their wares accurately, and astute enough to price them realistically. If you're really fortunate, you'll locate the item you want from a ham across town. If you like what you see and it performs acceptably, pay the money and cart it home. Unfortunately, this is not the usual scenario, so, in the used gear arena the arm's-length deal remains a viable option. Prepare well in advance and have all of your "what-ifs" covered. Make up a memorandum of agreement, especially if it's a big ticket item. List as simply and succinctly as possible the description of the equipment and the terms of the deal. State clearly that money will be refunded if expectations are not met. Prepare two copies of the agreement and have a place for dates and signatures.

Still skeptical?

Thousands of deals have been consummated through the nets, so rest assured that the method works. Don't be overly apprehensive or hesitant to give it a try. You might even test out the system and gain some confidence by purchasing a low-priced item. When the package arrives, open the parcel immediately as the delivery driver stands by. Document the existence of any problems and file your claim without delay. If you're still a bit leery about dealing with someone a goodly distance away, check for horsetrader activity on the local VHF/UHF repeaters. If you can't locate an active group, suggest the idea to the club officers and perhaps consider being the net controller—most hams have a little horsetrader in them. I guess it's in the genes!

Acknowledgments: Special thanks to two gentlemen, net controllers Evan K9SQG (Sunday 7275 kHz 0930 EST) and Bill KJ8I (Monday 3898 kHz 1900 EST), who contributed net controllers' insight and perspective to this article. Dave WA3GIN, a dedicated horsetrader with a sense of humor, allowed me to include his E-mail comments on my note outlining some of the material being included in the article.

Dave wrote, "Yeah...make sure you talk about the folks who want new, in-the-box-with-the-manual, one-owner, non-smoker, guaranteed mint-condition, double-boxed, shipped UPS, but are willing to pay 1/10 the list price of the equipment, and of course the seller pays the shipping." 73

Net Operation Protocol

Log in by callsign *suffix* alphabetically at the net's outset. If time permits late check-ins are listed.

Prices of items being offered may be listed; however, any negotiations are by "twisted pair."

Prices need not be offered on the air at listing time.

A request for a specific item is OK.

Equipment must be in the lister's possession. *No third-party offerings!*

Condition should be honestly represented (scale 1-10) with any pertinent discrepancies noted.

Schedule of Traders' Nets (all times EST)

Monday	7:00 p.m. (0000Z)	3898 kHz	General equipment (packet related computers OK)
Tuesday	8:00 p.m.	146.880/280	General equipment (NYC area)
Wednesday	10:00 a.m.	7251 kHz	General equipment
	8:00 p.m.	3945 kHz	
	8:00 p.m.	3865 kHz	
Thursday	6:30 p.m.	3875 kHz	AM equipment (sideband check in OK)
Friday	8:30 p.m.	3870 kHz	General equipment (Texas)
Saturday	8:30 a.m.	3985 kHz	General equipment
	10:00 a.m.	7275 kHz	Old gear/amplifiers/components
	8:00 p.m.	3865 kHz	Drake and other older tube-type radios
Sunday	9:00 a.m.	7275 kHz	General equipment (two consecutive sessions run)
Note: At the completion of this Sunday session, there is often a computer net.			
	12:00 p.m.	14.317 kHz	Icom Net
	3:00 p.m.	14.363 kHz	Collins Net
	5:00 p.m.	14.275 kHz	Heath (not confirmed)
	5:00 p.m.	3942 kHz	General equipment
	8:30 p.m.	3922 kHz	General equipment

Build the Mag-Glass

Combine the best of the through-glass and the magnetic-mount antennas.

David K. Pelaez AH2AR/5
7309 Centenary Drive
Rowlett TX 75088

I had pondered, long and hard, on an antenna mounting system that utilized a through-glass type antenna—one that could be easily removed and remounted.

One type of commercially-made system I'd seen was a flat spring clip that connected the coupler and the through-glass antenna together, hinged like a clamshell. The problem with this system was that it required the through-glass antenna to be placed near the top of the window because the clip was designed to ride over the edge of the rolled-up window glass. Not only does this design limit your mounting options, it also brings the radiator very close to the gutter and roof.

Why not just use a "standard" magnet-mount antenna, and mount the antenna to the roof or trunk lid? This option also has its limitations. Magnets do not adhere to Fiberglas™ body panels, and magnet-mount antennas, even with rubber boots, will scratch the clearcoat or paint of the car if you aren't careful.

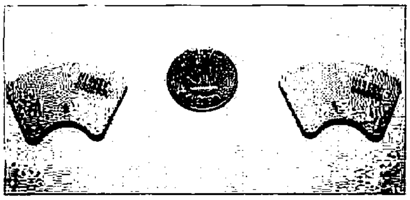

Photo A. The petal-shaped rare earth magnets, used after the creation of the original design.

New ideas

Someone once said that there is no such thing as a new idea; new ideas are just the synthesis and combination of old ideas. I knew there had to be some way to attach a through-glass antenna to an automobile window so that it wouldn't be necessary to pry the coupler and antenna off. Normally, through-glass antenna systems come with sticky pads on the coupler footprint and the antenna pad footprint. Once the pads are applied to the opposite sides of the glass, prying them off the window means replacement with new sticky pads. For temporary use, that's just not practical.

> ***"Once centered, these magnets had a grip like a gorilla!"***

Searching the junk box produced six neodymium iron-boron magnets I'd purchased several years earlier at Midwest Surplus, in Fairborn, Ohio. Rare earth magnets are used in high-efficiency generators and precision high-speed/high-torque electric motors.

Initially, I was amazed at their magnetic strength, and thought at the time that they might be useful for holding glued wood laminates together to support a woodworking project. They are, far and away, stronger than any conventional magnet available, and as I found these magnets were strong enough to stay in place on opposite sides of wood laminates up to three-quarters of an inch thick, I tested their strength on automobile glass and was equally impressed when I sandwiched the glass between two of these magnets. The magnets came together with a muffled snap, and I spent the next minute or so trying to remove them from the glass. Once centered, these magnets had a grip like a gorilla! My through-glass antenna problem had been solved.

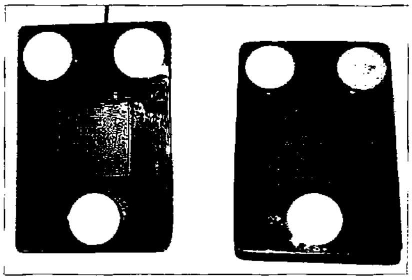

Photo B. The glass-contact side of the Mag-Glass baseplates.

Materials

The through-glass antennas used in this project are two-meter and 900-MHz antennas from Valor. Of course, any type of through-glass antennas should work. The Valor design has a fairly symmetrical base and I found their basic design makes cutting the Plexiglas™ I purchased at a hardware chain store relatively easy.

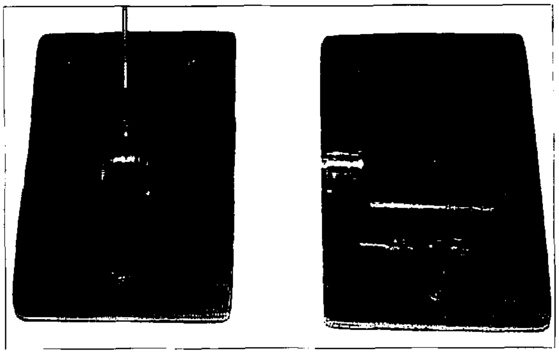

Photo C. Baseplates with epoxied antenna pad and coupler. The Plexiglas was painted black after construction.

Prototype #1 was made with 1/4-inch Plexiglas. The second prototype was made with a thinner 3/16-inch Plexiglas. Either of the two thicknesses will work, but my preference is the lighter 3/16 inch. I used a Dremel™ drill with a cutting bit to countersink the magnets into the Plexiglas. A barrel or cylindrical rotary file bit works well in routing out the Plexiglas (be sure to wear eye protection when routing out the holes). Slow-cure epoxy forms a bed for the magnets and holds the coupler and antenna base in place.

For this project, I used quarter-sized Neodymium iron-boron magnets (whose source has dried up), but equally strong and slightly larger Neodymium magnets are now available surplus through Marlin P. Jones and Associates (ordering information at end of article). Their magnets are not round—they are petal-shaped (**Photo A**).

You'll need twelve magnets for this project: three magnet pairs in each Plexiglas baseplate. The magnets are paired, then mounted and epoxied as single units into the Plexiglas. The dimensions and magnet placement shown are approximate, and not critical. The three magnets are placed in a triangular configuration; this placement seems to be the best orientation as it allows mounting on both flat and slightly curved glass surfaces.

Cutting

A coping saw, handsaw or scroll saw can be used to cut out the rectangular baseplates. Once you have cut out two baseplates, lay out the antenna coupler and the magnets in the configuration shown in **Photo B**. Using a sharp scribe or awl, scratch/trace the magnet and coupler outlines on the Plexiglas. If you are using the Valor through-glass antenna, pry off the rubber boot that hugs the circumference of the antenna pad. Once you remove this rubber boot, the antenna pad footprint will be slightly smaller than the coupler footprint (**Photo C**). This will not affect antenna performance. To hold the magnets in place for the tracings, you can use the other three magnets.

Be sure that both Plexiglas baseplates are configured so the magnets and coupler/antenna pad align when placed together. Once the tracings are done, remove the magnets and coupler, and countersink holes for the magnets and coupler.

"Please remember to slide the opposing baseplates away from each other—never try to just pull them apart."

Using a high-speed drill with a cutting bit, cut a pilot hole into the Plexiglas, about 3/32" deep (the depth of a single unpaired magnet). Use this hole as a depth guide for routing out the interior cavity for the magnet. Follow the tracing, and after completion, check to see how the magnet fits into the depression. Be careful if the fit is tight—it might be difficult to remove the magnet if you cut *too* accurately.

Now cut out a square hole for the coupler and the antenna pad; this can be done with a rotary file on the drill. Make a rough cut with a coping saw, and finish the sides of the cut with the drill. The coupler and antenna pad will be placed into the Plexiglas assembly so they will butt up against a glass surface, so they must be able to pass through the Plexiglas baseplate. A tight fit is desirable, but not essential. Before gluing the coupler and antenna pad, the magnets must be glued and pressed into their wells.

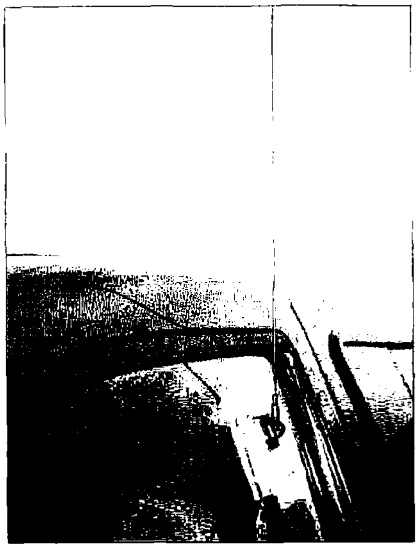

Photo D. Mounted prototype #1, stuck tight and working great.

Gluing

The magnets come from the supplier in a stack. I am not exaggerating when I say that it will take muscle to separate them into six pairs. You may find it easier to slide them apart by pushing them against a counter- or tabletop. Once you've got them separated make sure they stay that way by putting a buffer (scraps of Plexiglas, cardboard, etc.) between them. If they accidentally snap together, the force of impact can be enough to cause damage.

With a small drill bit, centered over the magnet depression, drill a small "weep hole" through the baseplate. When epoxy is loaded into the depression, this weep hole will allow some epoxy to escape when the magnet is bedded into the depression.

Check the magnets' mating to ensure that north-south polarity and magnet orientation are correct before gluing. Otherwise, the magnets will repel instead of attract when you try to put the baseplates together. Once the magnet pairs are glued and bedded into the Plexiglas, there will be a 3/32" space between the baseplate and the window surface. This 3/32" is the height of a single magnet that will be protruding from the well. The magnets will be riding on the surface of the window: as long as they are free of iron filings or other magnetically attracted debris, the smooth-coated magnets will not scratch the glass. Before you proceed with gluing the coupler and antenna

pad on their baseplates, be sure the paired magnets are glued and pressed into their respective wells.

The coupler and antenna pad

Once the bedded magnets and epoxy have dried/cured, it is time to glue the coupler and baseplate. Put the baseplate magnet-side-down on a smooth flat work surface. Push the coupler in from the top of the baseplate until it touches the work surface. Run an even bead of epoxy around the top edge of the coupler where it enters the baseplate. To keep the epoxy from oozing out between the coupler and the side of the cut-out baseplate before it sets, I found that coax sealant, available at electronics hobby stores, is a good temporary fix. Before gluing, keep the coupler aligned. Make a very small "rope" of coax sealant and put this material in any open gaps between the coupler and the baseplate to act as a removable dam.

The antenna pad is glued in the same manner, but I opted to fill the top of the antenna pad with epoxy as it sits a little differently from the larger coupler. The antenna pad, being physically thinner and smaller than its coupler mate, sits inside the Plexiglas baseplate in a well. I filled the well with epoxy, and also dammed the other side with coax sealant (once the epoxy cured, I removed the sealant).

Tips

Once the epoxy is completely cured it's time to try the antenna system out (**Photo D**). When placing the baseplates on the surface of the glass, put the opposing baseplates about six to eight inches away from each other on the glass and then slide them together. To remove your antenna from the vehicle, slide the baseplates apart; don't try to pull them apart. *Caution! Never put them on a metal surface*. If it is a painted surface, you will most assuredly scratch the paint. Do not place them on the hood or roof prior to installing them on the glass. The rare earth magnets are very strong—their attraction for metal surfaces is incredible, so be careful. When the antenna is mounted on the vehicle, follow the steps the manufacturer recommends for tuning. I have noticed that once the antenna is tuned (if the antenna is tunable—some through-glass antennas aren't), minor differences in glass thickness or antenna placement have little or no effect on VSWR.

What manufacturers don't tell you

Be aware that there are a number of newer automobiles with "passivated" glass. This glass tinting is created with a metallized spray process called "sputter coating," and is usually bronze- or silver-colored, but is available in a number of dark tints. This tinting process bonds a very thin layer of metal to the surface of the glass, and one of the unfortunate side effects of the coating/tinting is that it is RF opaque, which means radio frequency energy has a difficult time passing through it, and in some cases, can attenuate an RF signal by as much as 30 dB. Cell phone through-glass antennas, or any other through-glass ones will be attenuated when passing through this type of glass. Shifting to a different window, one that doesn't have the tinting, will solve the problem, but switching antenna locations would be a whole lot more difficult if you had used a permanent-mount through-glass antenna.

Storage

When storing this antenna after use, make sure you don't put the two baseplates together without a buffer of some kind—you can damage the Plexiglas or even pull a magnet out of its bed with the strong magnetic force. It is also not a very good idea to store this system near your priceless 3-1/2 inch floppies, or set it on top of your computer's hard drive.

If you want to keep the cost of this project down, one approach is to use six magnets instead of six pairs. I feel that the extra strength provided by the pairs pays off in security, though. They'll hold tight through the thickest automotive glass.

In researching the cost of new rare earth magnets, I found that they would cost about $40 *each* if bought singly from a company in Dallas. Surplus Neodymium iron-boron magnets are available by catalog from Marlin P. Jones and Associates. The part number is 7454-MG, and they are priced at $1.40 each. Call toll-free (800) 432-9937.

Maximize Your Transceiver's Tuning Range!

Computer control for the Ramsey transceiver kit.

Richard E. Lucka WD8BNR
162 Olde Mound Lane
Pickerington OH 43147-1180
[rlucka@aol.com]

The Ramsey digital transceiver kit series includes rigs for 6 meters, 2 meters, 220 MHz, and 440 MHz. Each is capable of programming 12 frequencies, or channels, using diodes. The rigs have good receiver sensitivity with plenty of audio output and transmit at about 5 watts. The rigs are perfect for mobile and packet applications.

You can maximize the frequency capabilities of your Ramsey rig and use IBM-PC software to (to name a few):

• tune all available channels within the ham bands (and transmit, too)

• scan and listen to many more frequencies outside the ham bands

• listen to both repeater outputs and inputs with a touch of a function key

• adjust the scanning rate and signal drop wait rate

• scan up or down frequencies using increments you select

• scan frequencies using a frequency list you can build

• divide your frequency list into categories (i.e., ham repeaters, police, fire, business, paging, hospitals, MARS, etc., etc.)

• survey within a frequency range to create a file of active frequencies

• create a packet control program to monitor a frequency and at times transmit a beacon on other frequencies letting the world know what frequency you are monitoring

• temporarily lock out frequencies while scanning (some digital pagers are annoying!)

... and on and on and on—all limited by your imagination and programming skills (if you "roll your own").

Intrigued? Then read on to see how you can build the IBM-PC computer interface that connects between your transceiver and PC parallel port.

Fig. 1 shows the interface circuit built on a Radio Shack™ 276-150 prototype board mounted on top of the transceiver's adder chips (U7 through U10). **Fig. 1** also shows a computer cable running through the modified transceiver power inlet and the necessary connections between the interface and the rig's main board. The other end of the computer cable connects to your PC's parallel port. **Fig. 2** shows additional mounting details using leftover cable insulation as legs and one corner resting on top of crystal Y2, held in place by twisted insulated telephone wire to the RECV bus wire.

The schematic (**Fig. 3**) shows the connection between the PC parallel port and the interface and another connection between the interface and the transceiver. **Table 1** shows the structure of the parallel ports from a programmer's viewpoint.

Central to the interface circuit are U1 and U2, the MC4094 or MC14094. Each chip is an eight-stage shift/store register with three state outputs. A 4094 chip has four inputs and 10 data outputs. See **Fig. 4** for the chips' pin layout. Outputs Q1 through Q8 are

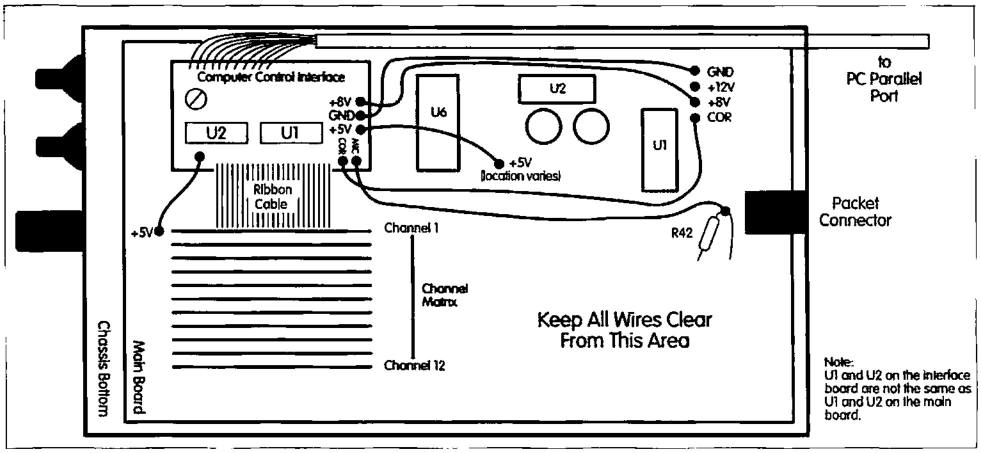

Fig. 1. The Computer Control Interface mounted above the Ramsey transceiver's address chips.

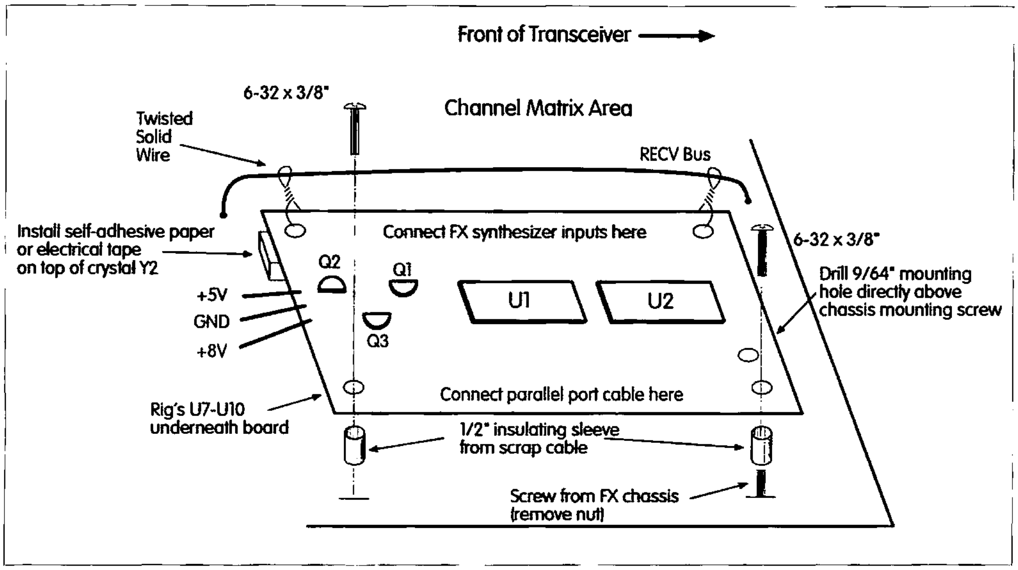

Fig. 2. Mounting details, view from the left side.

latches while Qs and Q's are serial outputs used for connecting several 4094s in tandem. The inputs are: data, strobe, clock, and output enable (OE).

A "latch" stores a voltage (low or high) and makes it available to the outside world from the chip. In our case here, the data is available for input to the rig's synthesizer chip. The term "low" means low voltage, or logic 0.

A "high" means high voltage (about 5 volts), or a logic 1. The term "rising edge" means a voltage transitioning from a low to a high (0 to 5 volts) and "falling edge" means the opposite.

When the clock input swings from a logic low to a logic high, data is shifted inside the chip's buffers. In other words, the data in the buffer for Q7 is moved to the buffer for Q8, then the data in Q6 is moved to Q7, and so on until Q1 is moved to Q2. The data that appears on the input data pin is moved to Q1. As long as the strobe input is low, the shifted data will not transfer to the output latch.

When the strobe input swings from high to low, the newly shifted data is latched to the output pins Q1 through Q8. Thus, after shifting new data, you only need to swing the strobe input from low to high and then back from high to low. If the strobe was already high and stayed there, when you shift data the outputs will reflect the data flow. For the sake of our circuit, we don't want to change the synthesizer inputs in a seemingly random fashion as we shift in the data of a new frequency, especially during scanning, so we must keep the strobe input low.

The output enable (OE) input determines the output state of Q1 through Q8. If OE is high, then the outputs contain logic lows and highs, depending on how you program the chip. However, if OE is low, then the outputs are "floating," or in a high impedance state. This is useful when you want to use the frequency selector switch on the transceiver and not let the chips interfere with other frequencies you select in the rig's channel matrix.

So, if you want to shift an eight-bit number into the chip's outputs (Q1 through Q8), do the following:

1. Keep the strobe input low and the output enable (OE) high.
2. Send a data bit into the data input.
3. Send a high to the clock input. The rising edge of the clock input causes the chip to shift all the data bits in the chip to shift one bit. The new data on the data input bit goes into D1 while the data in D7 goes into both Q8 and Qs. Having done this, send a low to the clock input. The negative edge of this transition causes the data on Qs to show up on Q's. Note that none of the bit transitions will actually appear on the D1 through D8 output latches as long as the strobe input is low.
4. Repeat steps 2 and 3 until all eight bits from a byte have been shifted into the chip.
5. Now, send a high and then a low to the strobe input. The falling edge of the strobe input copies the new data in the chip's buffers to the output latches Q1 through Q8. The new data will stay on the latch outputs no matter what is going on in the inputs, as long as the strobe remains low and OE remains high.

How the interface works in your Ramsey radio

The output enable (OE) input lends itself well to this project. It is hard-wired to the +5 connector from channel 1. If channel 1 is not selected (OE is low), outputs Q1 through Q8 will "float" and assume whatever state (high or low) as a function of another circuit.

The "other circuit" in our case is whatever frequency you select using the transceiver's frequency selector knob. Thus, when you select channels 2 through 12, you take away the +5 volts from OE and resistor R5 pulls the voltage down and causes the OE input to go low and the outputs to float. When you select channel 1, OE goes high and you will return to the frequency already stored in the interface and return to "computer control" mode.

OE shows up in bit 4 of the input port so your software can detect whether the interface is selected or not.

The interface has U1 and U2 in parallel with each other, not one in tandem behind the other. This allows only eight-bit shifts for both chips, rather than 16-bit shifts, which take longer to do. As you can see in the schematic, the interface does not use the Qs and Q's outputs.

U1 programs the upper eight-bit inputs (32k through 256) to the MC145152 synthesizer (the rig's U6 chip) while U2 programs the lower eight-bit inputs (128 through 1). Please note that the interface's U1 and U2 should not be confused with the transceiver's U1 and U2.

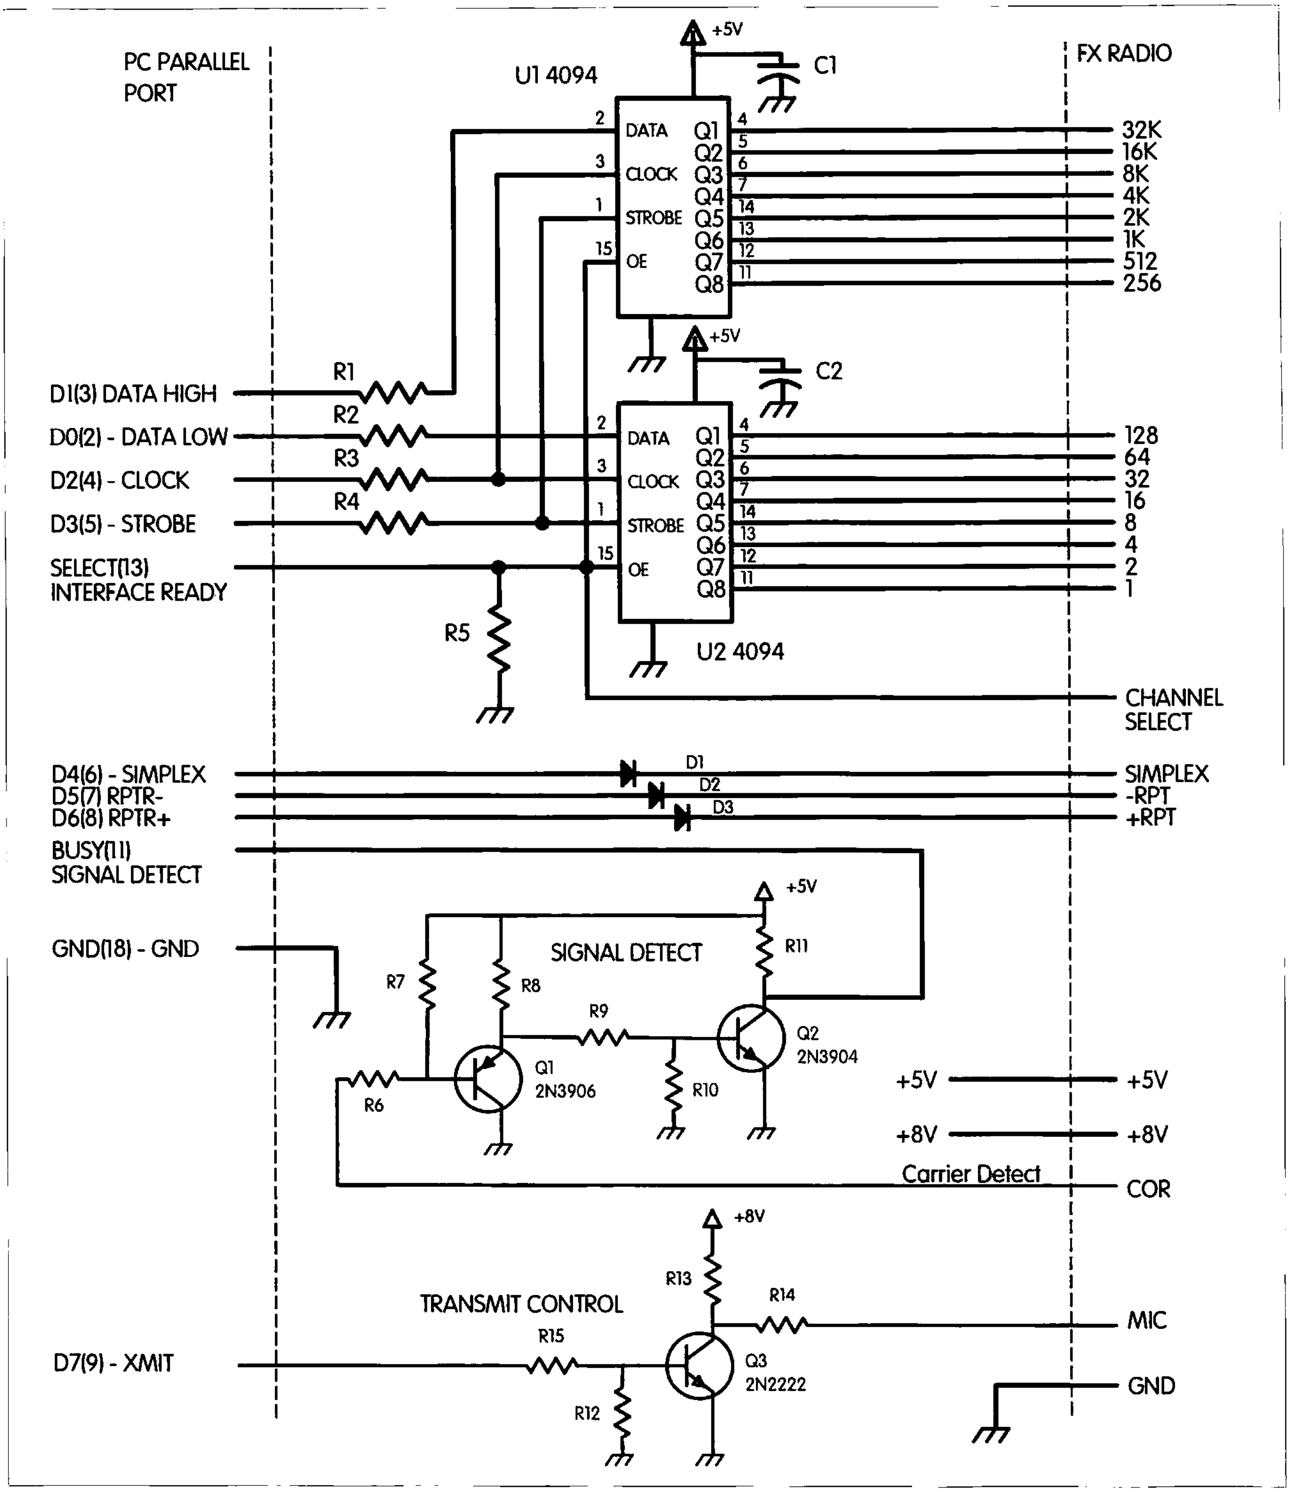

Fig. 3. Ramsey FX radio/PC interface.

The schematic shows the lower four bits of the PC's output parallel port being used for programming the inputs to the synthesizer. Bit D0 is connected to the data input of U2 while bit D1 is connected to the data input of U1. Your program will have to split the upper and lower halves of the synthesizer programming word (which is fully described in your Ramsey manual) and shift the bits (lowest bits first, or right shift) into the chips. Bit D2 controls the clock input and bit D3 controls the strobe input to both chips.

Bits D4 through D6 control the transmit offset selection on the transceiver. The programming of these bits must be consistent, and only one bit (D4, D5, or D6) can be high at a time. The Ramsey manual thoroughly explains how the transmit offsets work through the rig's adder chips (U6 through U10).

R1 through R4 limits current flow between the chip inputs and the PC

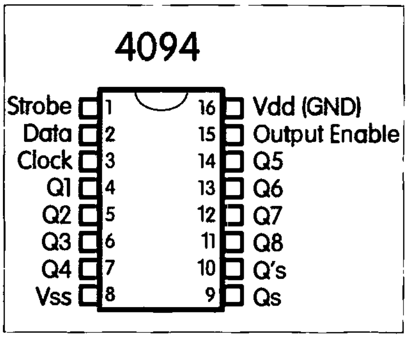

Fig. 4. Pin layout.

parallel ports whenever the PC is on and the radio (and interface) is off.

D1 through D3 protect the transceiver's 5-volt regulator when you have the transceiver on and the PC off.

Without these diodes, there may be a virtual short circuit condition when the PC is off which may cause the transceiver's 5-volt regulator to overheat and enter thermal shutdown.

The signal detect circuit allows your program to detect the presence of a signal. You can use this circuit to stop a scanning function if you sense a signal, and then resume scanning when the signal drops. The signal detect gets its signal from the COR output of the FX-146's product detector (U1). Since the COR is analog in nature, Q1 and Q2 convert the analog to digital and return a high for no signal and a low for a signal.

The COR output from your rig is part of the rig's squelch circuit. If you turn down the squelch until you hear background noise, the COR voltage will change and your PC will sense a "signal." In order for the signal detect circuit to work properly, adjust the squelch so that the background noise just drops off and leave it there.

The transmit control circuit uses the D7 output bit from the parallel port to control the transmit function.

This bit must always be low (for receive mode) when programming the frequency of the transceiver. Make sure you don't inadvertently set the transceiver in transmit mode by throwing random data on the output. In this circuit, R13 serves a dual function. First, it limits the collector current when you send a logic high to saturate Q3 and therefore lower the voltage going into the MIC input, which causes the transceiver to go into transmit mode.

Second, it keeps the MIC input high (keeps the rig in receive mode) if your PC happens to be off or in reset mode (booting up, when the output of the parallel port is in a high-impedance state). Connect the transmit control "MIC input" to the top of the rig's R42 (scrape away any insulating material first before connecting and soldering).

If, after assembling the interface circuit, the XMIT does not make your transceiver go into transmit mode, try reducing R14 to 68k or 47k. I had to do this for my FX-440 rig (100k was OK for the other three rigs).

Use the 5- and 8-volt supply directly from the transceiver. Both power supplies have ample reserves to power this interface.

Structure ot the parallel port data register:		
Port address: First parallel port (LPT1) = 378H Second parallel port (LPT2) = 278H		
	Function	Male DSUB
D0	Data low	Pin 2
D1	Data high	Pin 3
D2	Clock	Pin 4
D3	Strobe	Pin 5
D4	Simplex	Pin 6
D5	-RPT offset	Pin 7
D6	+RPT offset	Pin 8
D7	XMIT	Pin 9
Structure of the parallel port status register:		
Port address: First parallel port (LPT1) = 379H Second parallel port (LPT2) = 279H		
	Function	Male DSUB
D4	Select (1 = rig is on)	Pin 13
D7	Busy (0 = signal detect)	Pin 11
	Signal Ground	Pin 18

Table 1. Structure of the parallel ports.

A BASIC program showing how to program your radio can be downloaded from my FTP site. The ex-ample program requires Microsoft QBasic (available in DOS version 5 and above) or Microsoft QuickBasic version 4.5.

Additional programs are available from my FTP site. One is a deluxe, full-featured interactive scanner program, which you can run directly from the DOS command line.

How to find frequency limits

As with all radios, there are frequency limits. Ramsey doesn't tell you what the limits are, mainly because the limits can be changed somewhat.

They did tell you that your transceiver can be tuned to any 20 MHz segment, or 5 MHz segment for the FX-50. The transmitter range is much narrower, and it is just as well, so keep them tuned within the ham bands.

The transceiver's MC145152 frequency synthesizer has a Lock Detect output pin which, after being filtered, connects to the rig's U5, pin 5. You can connect a high impedance digital voltmeter to this pin.

When you tune to a frequency and it is within range, pin 5 will show about 5 volts, or at least more than 4 volts. If the voltage is lower than 3 volts, then you are out of range.

Remember, when building your kit, you had to tune your radio by adjusting coil L7 until you achieved a certain voltage at TP1 for a particular frequency? There is nothing sacred about the voltage value—it was Ramsey's way of ensuring that your radio would be tuned within a certain desirable frequency range, which would cover the entire ham band the rig was designed for.

You can tune L7 to move the frequency limits up or down. If you move the lower limit, you also move the upper limit. Just keep in mind that there is only so far you can go because of the limits of the coil and the overall circuitry (see **Table 2**).

Radio	Low Frequency	High Frequency
FX-50	48.650	54.550
FX-146	137.370	171.100
FX-223	204.270	265.900
FX-440	400.150	471.000

Table 2. Receiver frequency range for various radio models.

As you can see, the UHF radios have a higher frequency range than do the VHF radios. However, the transmitter still has a narrow range (by default, that helps to keep your transmissions within legal limits).

Availability

You can get all the software I have for programming your rig(s) using the circuit described in this article. The programs run in DOS mode. You'll find several programs in my FTP site; if you prefer, you can write your own software and use the frequency programming routines as a guide or an addition to your programs.

Send a blank diskette (5-1/4 or 3-1/2) plus five dollars (to cover S&H) and I will return it to you loaded with all the software I have. If you can access the Internet, check out my humble FTP site at [ftp://members.aol.com/rlucka/fxradio].

Please note one important point: Even though the Ramsey transceivers are capable of transmissions outside the ham bands, you must have an appropriate license to transmit outside the ham bands, just as you must be licensed to transmit within the ham bands. In addition, even if you are licensed to operate in a business segment that the Ramsey can tune to, the Ramsey is not type-accepted for use in these bands. Any excursions outside the ham bands must be "receive-only."

The FCC expects you to maintain strict control over your new capabilities and will enforce strict penalties for unlicensed transmissions, whether malicious or accidental.

If you have any ideas, suggestions, questions, whatever, feel free to contact me with an SASE or E-mail me at [rlucka@aol.com]. I plan to add to or improve the software and leave the latest versions in my FTP site, so check in once in a while to see what's improved or new. Some of the additions and improvements may be from your ideas, so communicate!

The transceivers are available in kit form from:

TV/VCR Tuner Applications (Part 3)

Hugh Wells W6WTU
1411 18th Street
Manhattan Beach CA 90266-4025

Spectrum analyzer

Perhaps one of the handiest tools for electronics is the spectrum analyzer. In essence, it is a receiver having an oscilloscope attached which is used to provide a spectral view of a band of selected frequencies. The amount of spectrum to be viewed can be varied for either a close-up view of the signal, or a greater amount for viewing all of the adjacent signals within the band. The usefulness of the spectrum analyzer is great, with many applications. To name a few: transmitter sideband analysis, spur generation analysis, frequency spotting and identification, identifying modulation mode, harmonic signal analysis, and use as a wide frequency range receiver.

The spectrum analyzer described here is constructed using relatively easy to obtain components so that it is a project within reach of any ham experimenter. The two main components are the TV/VCR tuner and a receiver. Although a receiver board may be constructed, almost any receiver capable of tuning to the tuner's IF (46–63 MHz) and having an AM detector will create a fine spectrum analyzer. I assume that you prefer to use a pre-built or commercial receiver, so a simple home-brew receiver will not be discussed. Many suitable receivers are available that will tune the 46–63 MHz region, such as six-meter AM and 30–50 MHz WWII military receivers. Even a 27-MHz CB AM radio used in conjunction with a 47- to 27-MHz converter will work well. The narrow IF bandwidth of the receiver provides narrow dispersion for viewing signal carrier and sideband characteristics.

The block diagram in Fig. 1 shows the major components and interconnects for a spectrum analyzer. When in operation, a sawtooth voltage is applied to the tuning voltage line, causing the tuner to sweep across a band of frequencies. Any received signal within that band will be translated to a DC voltage whose amplitude is relative to the strength of the signal which is then displayed on the vertical plane of the oscilloscope. In order to maintain a steady display on the screen, the horizontal scope sweep must be synchronized with the sawtooth generator. The sweep speed is set just high enough to eliminate viewing flicker. A high sweep speed does nothing to improve the display. Any basic oscilloscope may be used, but perhaps the main requirement for the scope is to have a DC input so that it will respond to the rectified output signal from the receiver's AM detector.

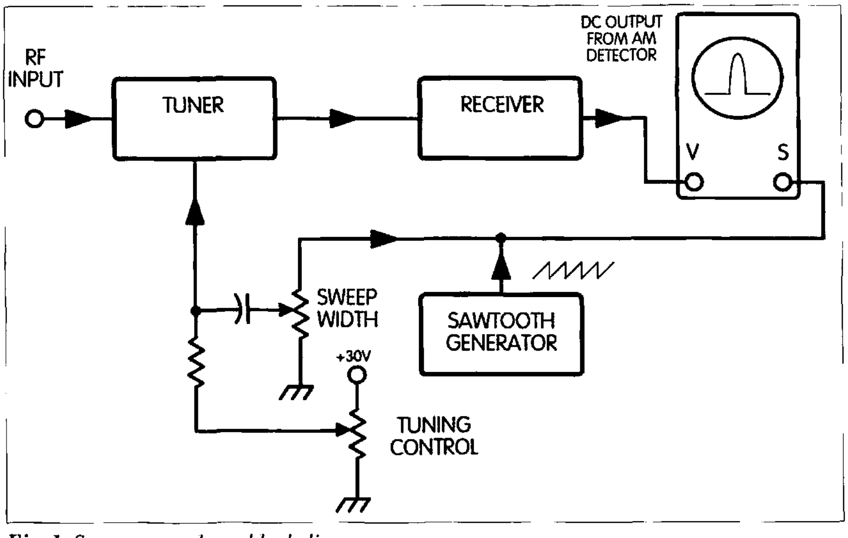

Fig. 1. Spectrum analyzer block diagram.

Fig. 2 shows the complete schematic for the spectrum analyzer with the exception of the receiver details. To drive the tuner sweep circuit, a unijunction transistor was chosen to generate the sawtooth waveform, but any sawtooth generator circuit will work in this application. In order to provide a fairly linear sawtooth ramp, a JFET is used as a constant current source for charging the timing capacitor. A voltage pulse is taken from the B2 terminal of the UJT to provide a sync pulse for the scope.

As an alternative sweep source, some oscilloscopes provide a horizontal sweep sawtooth output which may be divided down with resistors and applied to the sweep width pot. The sweep voltage amplitude as generated within the scope may be as high as 100 volts, but the maximum desired sweep voltage is about 10 volts when applied to the sweep width pot. On the average only 0.5 to 1 volt is required to provide a normal spectral display (sweep width).

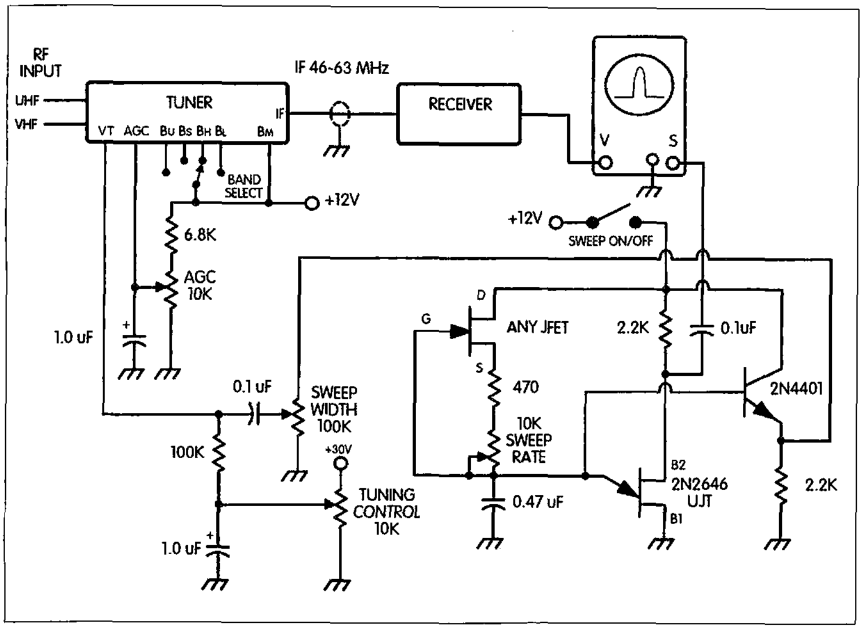

Fig. 2. Spectrum analyzer schematic.

Power supply regulation, although not as critical for the +12 volt line, is recommended to reduce tuner drift. Regulation is very critical for the tuning voltage circuit, however, and care must be taken to remove all ripple and noise. The tuning is performed by using a 10k pot across the +30 volt source. For vernier tuning control, a 10-turn pot and a counter knob are recommended.

Almost any small 24–28 volt, 100-200 mA, power transformer is suitable for use in the spectrum analyzer. It is suggested that filter capacitors have a value equal to or greater than 3300 µF to keep power supply ripple and noise to a minimum.

Mechanically, the circuit is very stable and can be mounted in any convenient manner to suit your taste.

Signal source

TV/VCR tuners were designed to be the front end of a receiver. As such, they contain a local oscillator which is used to mix with the incoming signal to create an IF of approximately 47 MHz. The tuner, as a receiver front end, covers a received frequency range of 45 to 900 MHz. The oscillator operates above the received frequency and is offset by the IF (46-63 MHz). Therefore, the oscillator operates over the range of approximately 90 to 950 MHz. The actual oscillator range is dependent upon the specific tuner. Typically, TV oscillators tune from 91 to 940 MHz while VCR oscillators tune from 108 to 955 MHz.

Some tuners are set up with a phono connector near the oscillator circuit that outputs the oscillator signal to the PLL frequency control circuit. In most cases, the output is frequency-divided prior to exiting the tuner case, making the output generally unusable. However, some tuners provide a direct oscillator output, and when that is the case, the tuner will work as a signal generator without modification. When

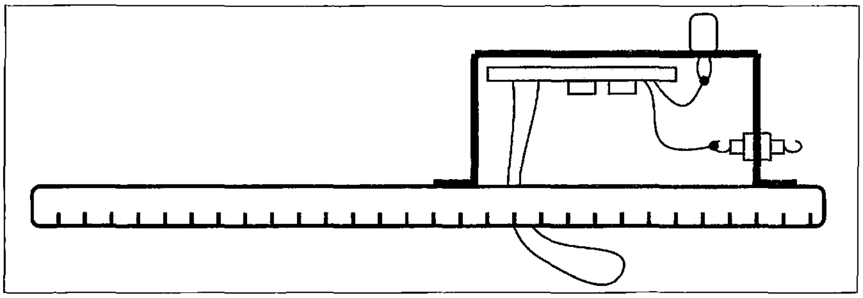

Fig. 3. Amplifier mounting and coupling. The pickup loop feeds signal from the oscillator to the amplifier board.

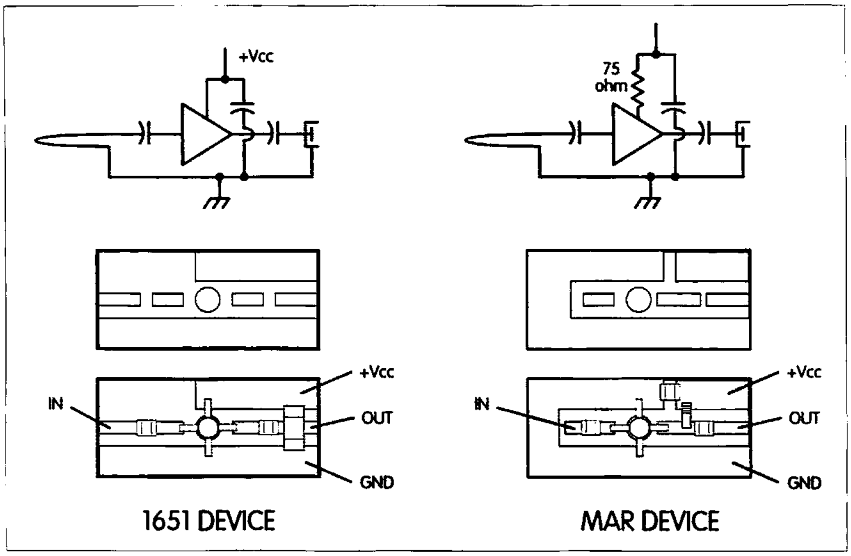

Fig. 4. Schematic, PC board layout, and parts placement for the amplifier board, shown for the two devices discussed in the article.

access to the oscillator is not available, the tuner may be modified slightly to obtain a direct signal from the oscillator. There are many techniques available to capture the oscillator signal, but only one technique will be described here.

The concept for capturing the oscillator signal is shown in Fig. 3 and involves drilling a hole in the tuner cover to provide access for a wire pickup loop to pass through the hole, allowing the loop to lie close to the oscillator circuit. The loop picks up a signal which is fed into a broadband amplifier. A coupling capacitor is connected between the loop and the amplifier to satisfy the isolated DC input requirement of the amplifier. The amplifier provides a constant load on the oscillator and is used to amplify the signal captured by the loop. If the tuner cavity is large enough, the amplifier may be mounted inside of the tuner rather than on the cover. Otherwise, the amplifier must be mounted outside of the tuner. To prevent radiation from the amplifier, the circuit must be enclosed in a metal box made from a tin can. The box is made RF-tight and soldered to the tuner cover. The box may be of any convenient dimensions, but it must be RF-tight.

Power for the amplifier is in the range of 4.5 to 5 volts. To prevent chip heating, the voltage at the chip should not exceed 5.5 volts. The power to the amplifier must be fed via a high capacity feedthrough.

A phono connector may be mounted on the amplifier box and used as an RF output connector. The amplifier output impedance is 50 ohms. To provide proper amplifier operation, the chip is mounted on a small piece of printed circuit board which is glued to the inside of the box.

The amplifier chip used in the original design of the circuit was an NEC UPC1651G. As an alternate part, a Mini-Circuits MAR-1 or MAR-2 may be used. A 75 ohm 1/4 watt resistor is used with the MAR series chip to source Vcc to the chip. An output impedance of approximately 40 ohms is achieved, which will source a 50 ohm line satisfactorily. The respective chip circuits are shown in **Fig. 4**. Capacitor values used in the circuit are not critical, as any value from about 0.001 to 0.5 uF will work. It is important to keep the physical size of the capacitor small and lead lengths kept very short. Chip capacitors are preferred when available.

After making the tuner into a signal generator, it will still function as a normal signal converter/tuner. The addition of a pickup loop will shift the oscillator frequency a small amount, but not enough to prevent the tuner from functioning as designed.

Multifunction signal device
